[Our experience of the management of poultry shows tends to convince us that there is always a great difficulty to committees in pursuing the exactly midway course that insures entries in due proportion to the appointed prizes on the one hand, and at the same time gives general satisfaction to exhibitors of different varieties of poultry on the other. Each breeder most probably selects for his choice his own particular "hobby," and fancies it the most deserving of support and distinction—in fact, supposes for the time being the breed he then holds superior to all others: hence, on the part of exhibitors, discrepancies must always prevail as to the opinion of which breed of fowls is the most deserving. Committees, on the other hand, are compelled not unfrequently, as expressed by homely phrase, "to cut their coat according to their cloth," and thus are forced to the really unenviable task of a selection among the numerous classes of such breeds as must be among the most limited, as to the amount of premiums offered. Unfortunately, statistics of their previous meetings are not invariably trustworthy to committees, for it frequently happens a class comprising only three or four entries one year calls forth the succeeding season perhaps quadruple that number, for the simple reason that, as the prizes were so easily won formerly, the next trial induces a great number of expectant winners to enter into the competition. This variation of entries seems beyond the power of computation, and thus the number of com-

petitors is altogether conjectural until the close of the time for entries makes plain the matter in dispute. Of course, even committees have their partialities for different varieties equally with the exhibitors themselves; and however anxious to arrange their schedule of prizes to meet the views of all those most interested, they must fail occasionally in so doing.

It should be kept always in mind that any show to be successful must be self-supporting; for the cases in which a voluntary subscription is to be depended on among the non-exhibiting but resident gentry is a most unusual occurrence, and a resource that after a few repetitions speedily becomes threadbare to the very core. After all experiments that have been introduced it seems that equal payments for the privilege of competition, with equal amounts gained by the successful ones in each class, is the most universally-approved arrangement. True it is, at the outset a few (and in some instances very few), pens compete, and the loss to the Society by certain classes is considerable; but, in many cases where the attempt has been renewed, the entries the year following have been so strangely reversed, that in the aggregate of the two years an absolute gain has been obtained.

We think with our correspondent, "Y. B. A. Z.," that the time the birds are detained at Worcester is too lengthy. The fact is, a better and a larger show would undoubtedly be insured had its duration been of a less protracted nature, particularly as chickens invariably suffer more from confinement than aged poultry. We trust, therefore, the Worcester Committee may think well even yet to reconsider this matter, with the view to meet the wishes of exhibitors generally, more especially as their Poultry Show of this season should boast of a very greatly-increased amount of support, on account of its taking place during the time of the Royal Agricultural Society's Meeting at Worcester.]

TAUNTON POULTRY ASSOCIATION.

THIS well-managed and remunerative Society, according to an advertisement which appears in our columns to-day, is "dissolved." This causes us much surprise, because, as some comic character observed on an undesired death, "there was no occasion for it." We are not astonished when a society retires to the catacombs after being ill-conducted, or when it is in debt, but neither of these "occasions" befell the Taunton Association. No secretary could have ministered more satisfactorily than Mr. Ballance; and we see in the printed accounts that there is a small sum in hand.

We do not think that a valid reason for dissolving is "the subscribers having failed to attend the meeting"—a more cogent reason would have been their "having failed to subscribe." Much do we hope that the subject will be reconsidered—that Mr. Ballance will resume the secretariat; and, we think, that subscriptions will increase rather than diminish, if application is made for them, when the threatened extinction of the Association is thus publicly known.

APIARIAN NOTES.

OPEN BEE-HOUSES.

THERE is nothing at all novel in the advocacy of open bee-houses; and if "A. K. H." will turn to No. 10 of Vol. XXIV., page 161, he will see that I have written in favour of them, though in a modified form. It is recommended that the hives should be on separate pedestals, but there is not the slightest objection to a double rail for their support, and in some respects this would be found to be the most convenient plan.

But, surely "A. K. H." cannot have tried the form of open house he has described at page 179, or he would hardly have brought it forward as an improvement on any known method of protecting hives. He would find it, as he has figured it, anything but a protection for his bees. The double tier of hives is fatal to it. To work supers the roof must be at such an elevation above the lower tier that rain must freely drive in at the front and back; and as to the high exposed sides, the hives might as well be out in the open air altogether. I thoroughly detest hives being placed one above another, even if the upper entrances are not immediately over the lower. Let the upper tier be dispensed with, the roof brought down to a proper distance, allowing ample room for supering, and there can be no objection to the plan. But I would do a little more before I should consider my hives safe from driving rain; the ends should be closed-in with some material, such as pieces of old floor-cloth,

matting, or boards of feather-edged deal. With a wide overhanging roof the hives would be thoroughly protected, and I have little doubt that there is no better plan of house or shed for keeping them to advantage. The back of the roof being made to open on hinges is a very great improvement and worth adopting.

Within the last two or three years I have made use of a large aviary about 25 feet long by 8 feet in width. The front is all wirework, the roof wood or galvanised iron; the back, sides, and top being quite closed-in. Having discarded the feathered occupants, it occurred to me to make use of the place as a bee-house. Parts of the wirework were cut away so as to allow plenty of room for the free flight of the bees. This has answered admirably in this place, though if it were not for the wire front the rain would probably drive in too much, as in the centre the roof is at least 16 feet in height above the ground floor. I find one very great advantage in performing operations in such a house—the bees do not readily enter through the meshes of the wirework, but they very quickly make their exit thereby, so that they seldom annoy the operator. If building a bee-house, I should be very much inclined to obtain some galvanised wire netting of very small mesh to form the front, cutting away spaces of about 8 inches by 5 for the bees. This would allow of ample circulation of air; yet be of considerable use in preventing annoyance to the bee-master from his angry subjects.

BEES IN BUILDINGS.

A short time ago I expressed myself rather adverse to keeping hives in buildings or in rooms in dwelling-houses. Since then I have received a letter from a friend giving an account of the state of his apiary, and speaking highly of the success of his experiment in making use of a large glass room originally built for the purpose of taking photographic likenesses. As he is totally unaware of the subject having been mooted in these columns, his opinion may perhaps be the more valuable. I may premise that he is an apiarian of long standing, and of far more than ordinary science and practical experience.

After giving an account of the present state of his apiary, and reporting the loss of most of his artificially-formed Ligurian stocks, he goes on to say, "My great success has been in the driven cottager's bees, formed into stocks last autumn; all these are alive and flourishing. They have been all carrying in pollen from the 30th of January and 1st of February, some of them in large quantities. These are all in my glass room, which really makes a first-rate bee-house. The temperature being equable and the room dry, the hives are earlier than any out of doors in my garden. There are seven stocks now in this room a good distance from each other, and there is less hovering and pitching about of strangers than in the garden. The floor-boards are dry and clean, and there has been no moisture on the windows all the winter. I enjoy this room vastly, and wish there were more hives in it."

So far as it goes this is evidence in favour of placing hives in rooms; but whether they will do well in this glass house for a permanency remains to be proved. I should fear the heats of summer would be very detrimental to their prosperity, and therefore must defer judgment until the close of the next autumn, when I hope we may have further and corroborative evidence of the suitability of such a plan for keeping hives.

BEST ASPECT FOR HIVES.

I do not think a "LANARKSHIRE BEE-KEEPER" can lay down any law as to the most suitable aspect in which hives can be profitably worked. That he is right in his decision that a sheltered north aspect is the best in his own locality or apiary I have no doubt or wish to dispute; but I am convinced that what would be the best aspect in one part of the country would be the worst in another. So much depends on prevailing winds or draughts of air, or the quarter from which most rain may be looked for, that it seems impossible to lay down any rule for absolute guidance.

Considerable attention has been paid by me to this very subject, and I confess that after numberless experiments I am unable to arrive at any fixed conclusion.

At this present moment I have hives facing nearly every point in the compass, and it is extremely difficult to say which are answering best. The finest takes of honey I have ever had have been respectively from east, south-east, south, and due west, and with me there is not much to choose between them; but I should in all cases be guided by what is in the garden, or near

enough to affect the bees by causing rough currents of air, or confining them too closely so as to distress them with a too sultry atmosphere.

My own inclinations rather tend to a south-eastern aspect with the shelter of a building or some large evergreen shrubs on the north at some little distance. If it can be obtained, a large bush on the south which shall in some measure shade the house about twelve o'clock, is always a desideratum, but it must in no wise interfere with the direct flight of the bees. Probably the most populous hive I have this spring, as it also was last year at the same period, is a hive facing due west. For some years past hives on this same stand have been remarkable for going through the winter with large populations, and in good or in tolerable seasons showing considerable returns from their labours.

It is far from my intention to write against placing bees in a north or any other aspect; all that I wish to contend for, is that the aspect most suitable in one part of the kingdom may not be so in another; and even more than that, a distance of only a few miles shall equally influence the judicious placing of bee-hives.—S. BEVAN FOX, *Exeter*.

BOTTLE-FEEDING FOR BEES.

SEEKING the above mode recommended in your columns, I have given it a fair trial this year and the last.

The principal disadvantage I have experienced is often of a morning finding a broad stream of food out from the entrances, and over the landing-boards. At first I concluded that the bottles must have toppled over, or that the double ply of fine cap-net had given way; but on examination the bottles were standing quite plumb and the net all right. Besides the injury this run over the combs and the main body of the bees in the very centre of the hive must cause, this stream externally attracts robbers from the strong colonies to the weak ones most in want of food, and I fear the consequences may prove disastrous. I also find feeding in bar-hives, which the most of mine are, through the narrow space betwixt the bars, a very slow proceeding in comparison to that in straw hives—for instance, where the neck of the bottle can be introduced into the hive amongst the bees. With these exceptions, which I trust some of your many contributors may assist me to overcome, I otherwise think it a vast improvement over all the other systems I have tried.—W. J.

[There is evidently something wrong in your manipulation of the bottle. Either some loose ends of string or net have caused the food to drip into the hive by means of capillary attraction, or the first rush on inverting the bottle has been so copious as to overpower the bees. Test your bottle before again using it, by inverting it filled with water and tied over with cap-net. If after being inverted the fluid remain perfectly suspended all is as it should be, and it will only be necessary when using it to invert it in the first place over the jug or other vessel containing the food, whence it should be carefully and steadily conveyed in the same position to the hive. Bees in bar-boxes may be fed with the same facility as those in common hives, if Mr. Woodbury's plan be adopted of allowing a free passage between the bars and crown-boards.]

BEES IN NORTH-STAFFORDSHIRE.—Pollen-carrying commenced on February 16th, and was brisk on March 1st and 2nd.—A NORTH-STAFFORDSHIRE BEE-KEEPER.

PRESERVING WOOLLENS FROM MOTHS.—The simplest and best way of preserving woollens through the summer from the destruction of moths, is to wrap them well up, after brushing and beating them in cotton or linen cloths. The moth can pass neither. Two covers well wrapped around and secured from the air will be effectual. An old sheet will answer.

OUR LETTER BOX.

DEALER IN ZOOPHYTES.—Can any of your readers recommend a dealer in zoophytes, residing on the coast, who is moderate in his charges? Not a dredger alone, but one who keeps a stock for sale, and is conversant with their habits.—EYESHAM.

WORK ON PIGEONS (*Almond*).—We know of no other work on the subject except those you name.

BEES OVERPOWERED BY MOTHS (*S. E., Swaffham*).—We have received the tin box containing a mass of cocoons, which shall be reported upon as soon as any of the moths arrive at maturity.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 51.9° and 33.6° respectively. The greatest heat, 75°, occurred on the 27th, in 1830; and the lowest cold, 14°, on the 25th, in 1850. During the period 161 days were fine, and on 91 rain fell.

ORCHID IMPREGINATION.

OWE Mr. James Anderson the correction of a misstatement; and as he has reproduced my letter in which the mistake was made, I will correct myself in your pages. I ought to have done so to himself privately, but I was not aware that he was so interested in the suggestion as he seems to have been.

The seed of *Odontoglossum* which he was so polite as to send me was not all barren. Some time after I had written to him the remarks which he quotes I thought I would institute a more prolonged and careful microscopical examination; and the result was that I found a few seeds—perhaps one in five hundred—in which the opaque embryo was clearly discernible in the midst of the twisted, netted, loose seed-coat. I therefore determined to sow it. In doing this I adopted the plan recommended by Mr. Beaton in page 61 of *THE JOURNAL OF HORTICULTURE* for 1862—in which the mode of dispersing the dustlike seeds by floating them on water, which is then let slowly off at the pot-bottom, leaving the seed adhering to the charcoal, peat, and crocks—struck me as beautifully ingenious, simple, and effective. This, then, I did; and the pot, standing in a saucer of water daily replenished and covered by a square of glass slightly tilted, has remained from last October till now, in shade close to the hot-water pipes in the Orchid-house.

Curiosity led me to examine the condition of the pot and its contents often; and the seed had not been sown long before I could readily discern, by the aid of a pocket-lens, the fertile seeds. These manifestly swelled and became of a tender green hue; and as the thin empty membrane of the numerous barren seeds gradually decayed away, the fertile ones were the more distinctly seen, especially on the black ground of the bits of charcoal. I presumed they were going to germinate; but one by one they disappeared, and for some time past I have not been able, with the closest scrutiny, to detect a single seed.

With regard to my suggestion of encouraging the access of bees to Orchid-houses I will add a word. While I still believe it would be found successful in securing the formation of ripe seed by many species that are now unfertile with us, I perceive a strong objection to the practice. It is known that the blossoms wither and die within a few hours after impregnation; and as this, under the free action of insects, would take place almost immediately after they had expanded, our magnificent spikes of flowers, which now adorn the house and fill it with perfume and loveliness for four, six, or eight weeks together, would scarcely last so many days. Only, therefore, in a few cases, in which the obtaining of available seed would be of superior importance to the preservation

of the bloom, would the free introduction of insects be proper. Yet, if once the raising of Orchids from seed could be depended upon as of ordinary plants, I cannot but think that it would soon become of mercantile importance as a source of obtaining specimens far more prolific than those on which we at present depend—viz., the importation of foreign specimens, and the subdivision of such as are in cultivation.

Moreover, as Orchids seem peculiarly liable to variation in the size, colour, and number of their flowers, the raising of them from seed on a large scale might reasonably be expected to yield a multitude of startling novelties, even in those species which, from long cultivation with us and wide dissemination (chiefly, however, by repeated fission of the same original), we are accustomed to consider as sufficiently familiar.

The desire to cultivate these most lovely plants is notoriously increasing, and would spread very rapidly but for the barrier presented by the high prices demanded for them. A great reduction in price would doubtless be the immediate result of an extensive and general production of seedlings. The little plants at two or three years old would be eagerly bought-up if once in the market, and grown on by many a charmed amateur, who would not venture upon the purchase of established plants ready to flower, such as are alone to be bought at our nurseries as yet. Then the interest attaching to the lengthening of the rhizome, the successive formation of larger and yet larger bulbs, the peculiarities of cultivation under such skilful teachers as Appleby and Williams, the watching for the development of flowers, would keep expectation alive; till at length the peeping-forth of the flower-sheath from some plump bulb of *Cattleya* or *Lælia*, the gradual rising of the dark bud within seen against the light, its protrusion, and the expansion of the gorgeous glorious blossom, would be confessed an ample repayment for all the anxiety, all the expense, all the labour. Surely there is a fortune to be made by some young nurseryman who will lay himself out for raising Orchid seedlings, or I am much mistaken.—P. H. GOSSE, *Torquay*.

THE ROYAL HORTICULTURAL SOCIETY'S
SECOND SPRING SHOW.

A FROSTY morning, a dense gloom hanging over the metropolis in the forenoon, and a chilly north-east wind for the remainder of the day, were circumstances by no means likely to be conducive to a large attendance of visitors; still the muster, especially of ladies, was very good, and, notwithstanding the cold and draughty place in which the Show was held, so great was the interest manifested in the flowers exhibited, that it was frequently a matter of difficulty to approach them.

Camellias and Hyacinths constituted the most prominent objects in the Show, but the former were not brought forward in such numbers as might have been expected.

In Camellias, a special prize was offered for the three
No. 756.—VOL. XXIX., OLD SERIES.

best. This was taken by Messrs. Veitch & Son, of Exeter and Chelsea, with *Valtevaredo*; General Lafayette, bright rose striped with white; and Countess of Orkney, white with rose stripe, the last-named being unquestionably the finest plant in the room.

In Class 1, six distinct kinds, Messrs. Veitch had the first prize for Madame Lebois, a fine imbricated deep rose; *Fimbriata alba plena*; Comte de Paris, a very fine plant and the flowers of a very delicate salmon pink; *Bella di Firenze*; and *Tentonia rosea*. All of these were handsome, well-flowered plants. Mr. Hally, of Blackheath, came second, being in fact the only other competitor in this class. His flowers were *Amabilis*, red; *Carminata*, a blood-red seedling; *Optima*, *Elegans*, Countess of Orkney, and *Imbricata*. Mr. Standish, of Ascot and Bagshot, likewise exhibited in this class, but not for competition, and the varieties which he brought forward were more recent than those in the second-prize lot. They consisted of *Lavinia Maggi*, very fine; Sarah Frost; Duchesse de Berri, a beautiful bluish white; Queen of Beauties, delicate rose, large and very double; *Maestra Rosa*; and *Bicolor de la Reine*, salmon and red.

In Class 2 there was no competition; and in Class 3, which was for four distinct kinds, Messrs. Veitch again walked over the course with handsome plants of *Triomphe de Lodi*, deep blush variegated with rose; *Alexina*, blush striped with rose; *Alba plena*; and *Amelia Benuco*, rose.

In Class 4, a single specimen, Messrs. Veitch were also first with a plant of *Princess Bacciocchi*, 5 feet or more in height and handsomely grown, its glossy foliage setting-off the crimson scarlet flowers to great advantage. The second prize was awarded to Mr. Salter, of Hammersmith, for a very fine plant of *Chandler's Elegans*, which was about 8 feet high, but not so bushy as the preceding.

In Classes 5 and 6, for *Rhododendrons*, there was no competition. In 7, that for single specimens, Messrs. Veitch had *Smithii superba*, a magnificent plant about 5 or 6 feet across and covered with its crimson scarlet flowers. To this the first prize was given; and the second went to Mr. Young, gardener to R. Barclay, Esq., Highgate, for *Rhododendron Blandyanum*, forming a dwarf standard about 3 feet high, and having six trusses of bright rosy crimson flowers. From the same exhibitor also came a plant of the small scented white *Ciliatum*.

The Hyacinths were superb; but the collections of Mr. Wm. Paul, of Waltham Cross, and Messrs. Cutbush, of Highgate, surpassed those of all others, both as regards the size of the spikes and bells and the excellence of the varieties shown.

Class 8 was for eighteen kinds, and here Mr. Wm. Paul was successful in carrying off the highest honours. Among the varieties he exhibited were *Koh-i-Noor*, a new and excellent double sort, with a magnificent spike of a delicate rosy salmon; *Marie*, a purplish-plum; *Duc de Malakoff*, fawn and nankeen, a fine addition to the yellow class; *Macaulay*; *Von Schiller*; *Mont Blanc*; *Solfaterre*; General Havelock; *Cavaignac*, very clear pink, and a broad spike; *Ornement de la Nature*, a delicate pink; *Snowball*, one of the finest varieties known; and *Florence Nightingale*, flesh. *Grand Lilas*, *Grandeur à Merveille*, *Howard* and *Baron von Tuyl* were also very fine. Messrs. Cutbush took second, though not without a close competition. In this collection were *Ida*, one of the best of the yellows; *Haydn*, a very fine lilac mauve; *Snowball*; *Koh-i-Noor*; *Garrick*, double blue; *Seraphine*, blush; *Grand Lilas*; *Duke of Wellington*; *Florence Nightingale*; *Grandeur à Merveille*; General Havelock; *Alba Maxima*; *Charles Dickens*; *Victoria Alexandrina*, a new and very fine crimson; and *La Prophète*, also new, pink-striped.

The only other competitors were Messrs. Carstairs & Sons, of Edinburgh, who had in their collection good spikes of *Amphion*, crimson; *Agnes*, bright rose; Lord Palmerston, a pretty blue; *Seraphine*; *Charles Dickens*; and *Ida*.

Class 9 was for twelve kinds, for amateurs only, and here the exhibitors were Mr. Carr, gardener to B. Noakes, Esq.; Mr. Young, of Highgate; and Mr. Taylor, gardener to C. A. Hanbury, Esq., of East Barnet, who stood on the prize list in the order in which they are named, but whose exhibitions fell far short of the excellence of the eminent nurserymen already mentioned.

Mr. Carr had fine blooms of Mrs. Beecher Stowe, *Von Schiller*, *Madame Van der Hoop*; and good examples of *Duke of Wellington*, *Charles Dickens*, and some others; whilst Mr. Young's collection contained a fine spike of *Howard*; *Koh-i-Noor*; *Prince Albert*, a good dark purple; *Princess Alice*, with large light blue bells; *Mont Blanc*, and other well-known sorts.

The next Class, 10, for six new kinds, only contained two exhibitions—those of Mr. Wm. Paul and Messrs. Cutbush, who were respectively first and second. Mr. Wm. Paul had *Macaulay*, which, as a rose-striped kind, was a gem; *Duc de Malakoff*, fawn; *Koh-i-Noor*, a splendid spike; *Haydn*, a beautiful mauve; *Snowball*; and *Florence Nightingale*. Messrs. Cutbush had *Feruk Khan*, a very good dark plum; *San Francisco*, a nice canary yellow; *Prince of Orange*, a fine deep rosy pink; *Maria Theresa*, with a close spike of a fine rose; *Rouge Eclatante*, a distinct double deep crimson; and *Fair Maid of Denmark*, with large pure white bells.

In Class 11, six pots, Amateurs, the first prize was withheld. Mr. Carr received the second, and among the flowers he showed were three nice spikes of Mrs. Beecher Stowe; *Lina*, small but of a fine crimson; and *Heroine*, yellow. In Mr. Young's, who was third, the best were *Grandeur à Merveille* and *Elfrida*, white.

Of early Tulips, there was again a good display, Messrs. Cutbush taking first in the class for twenty-four kinds; and Mr. W. Paul second. The former had *Grand Duc*, brownish-red with yellow edge; *Vermilion Brilliant*; *Cramoie*; *Duc d'Arenberg*, brown with yellow border; *Fabiola*, rosy violet and white; and *Rouge Luisante*, rose. Mr. Paul contributed *Grand Duc*; *Proserpine*, a rich rose; *New Yellow Tournesol*; *White Pottebakker*; *Tournesol*; and *Canary Bird*, yellow, but the flowers did not stand out so well from the foliage as in Mr. Cutbush's.

The next Class was also for six kinds, but for eighteen pots; and here again Messrs. Cutbush and Mr. W. Paul occupied the same relative positions, the former having *Duc d'Arenberg*; *Fabiola*; *Vermilion Brilliant*; *Florida*, purplish-violet; *Mathilda*, a showy red and white; and *Rouge Luisante*. Mr. Paul, whose exhibition was also excellent, had *Archduc d'Autriche*, a fine crimson and yellow; *Cottage Maid*, a pretty rose; *Standard Royal*, very showy; *Van der Neer*, a very fine purplish-violet; and *Striped Pottebakker*.

In the Amateur's Class, good pots of *Rex Rubrum*, *Tournesol*, *Perle Blanche*, and *Duc d'Arenberg* were shown by Mr. Carr, who was first. Mr. Young was second.

The Miscellaneous Class is always a large one, and on this occasion it occupied an unusually large space. Here Mr. W. Paul received a first prize for a magnificent collection of a hundred Hyacinths, among which we noticed as being particularly fine—*Macaulay*; *Marie*; *Howard*, brick red; *Snowball*; *Solfaterre*, a splendid spike; *Agnes*, bright pink; *Princess Clothilde*, a new and dark red; *Princess Charlotte*, a beautiful peach; *Ornement de la Nature*; *Aurora Rutilans*, a very fine colour—crimson; *Milton*; *Mirandoline*, pure white; *Duc de Malakoff*; and *La Nuit*, a very dark colour. *Couronne de Celle*, *Baron von Tuyl*, *Grand Lilas*, and other well-known sorts made up the remainder.

Messrs. Cutbush had also a splendid collection of one hundred pots, comprising most of the sorts above enumerated, and many other fine varieties. In Reds, *Susannah Maria* was a fine double rose; *Duke of Wellington*, a splendid spike; and of single kinds of the same colour, *Macaulay*, *Queen of Hyacinths*, and *Johanna Christina*, pale rose, were very fine. In Whites, *Sir Bulwer Lytton* was a fine double cream with a large spike; *Queen of the Netherlands*; and *Paix de l'Europe* had large spikes and pure white bells; and *Miss Burdett Coutts* is also a remarkably fine blush variety with very large bells, and the same may be said of *Tubalora*. In Blues, *Bride of Lammermoor* and *Pieneman* had very large bells; *Charles Dickens* and *Grand Lilas* were also fine; *Aurora* was a pretty straw colour tinged with pink; and *Duc de Malakoff* has been already mentioned as being an excellent new straw-coloured variety. This collection well deserved the second prize which was given to it; and Mr. Cutbush also received a similar award for twelve *Amaryllises*, of which *Admiral de Ruyter* was a rich ruby red; and *Eclatante*, a blood red with white streak. The other varieties exhibited were variously streaked with red or crimson and white.

Second prizes were awarded to Mr. Bull, of Chelsea, for a collection of new and rare plants, which were mostly the same as those exhibited at the previous Show; to Mr. W. Paul for four boxes of beautiful cut Roses, including *John Hopper*, *Madame Masson*, *Colonel de Rougemont*, and fine blooms of other leading kinds; and to Messrs. J. & C. Lee, of Hammersmith, for a collection of greenhouse plants, in which were a fine bushy plant of *Acacia Drummondii*, and two handsome specimen *Epacris*, *Eclipse* and *Miniata splendens*; several *Amaryllises*; *Eriostemon myoporoides*, a very ornamental

species; *Hedera tulipifera* and fuchsioidea, *Oncidium altissimum* with two fine spikes of flowers, and other plants.

Messrs. Veitch had also a fine collection, which included handsome plants of *Chorozema ilicifolia*, *Eriostemon densifolium* and *nerifolium*, and a beautiful specimen of the white-flowered *Rhododendron jasminiflorum*, *Azalea Exoniensis*, which was a splendid pyramid of crimson bloom, numerous varieties of *Lycaste Skinneri*, and other plants.

Of other objects, three boxes of cut Roses were shown by Paul & Son, of Chesham; cut Camellias by Messrs. Lee, of Hammersmith; and Mr. W. Paul, of Waltham Cross; *Bougainvillea* by Mr. Daniels, gardener to the Rev. C. R. Keene, Henley; collections of stove and greenhouse plants by Messrs. T. & A. Smith, of Dulwich, who also again exhibited their variegated *Hammerocallis elegans*, for which they had an extra prize. They had, besides several *Azaleas*, one of which, a double white, called *Flag of Truce*, received a special certificate from the Floral Committee. From the same firm there were also several seedling *Cinerarias*, the merits of which as well as of several other objects which were brought forward, we will leave to the pen of our talented contributor "D." of Deal, to describe.

Of tree *Mignonettes*, for which special prizes were offered, there were none to compare with the immense plants shown by Mr. Richards, gardener to Lord Londesborough, Tadcaster. These stood 5 feet in height and had fine, dense, pyramidal heads, which were covered with flowers. *Pandanus elegantissimus*, from Messrs. Veitch, and from Mr. Bull, of Chelsea, had a first-class certificate. *Trichomanes spicatum*, of a pellucid olive green, a dwarf and handsome species, came from Mr. Bull; as well as *Nephelaphyllum cordatum*, a terrestrial Orchid, forming a nice companion to the *Anætochilus*, the leaves of a very light green dotted and veined with olive green; and *Funkia univittata* with a broad white stripe up the centre of the leaf. From the same exhibitor also came *Yucca Stokesii*, *Begonia Sécrétaire* Morren, with very handsome silvery leaves, and two seedling *Geraniums*, *Beauty* and *Auriculá*, the former orange scarlet with white eye, the latter salmon with a white eye.

Rhododendron Romaine de Smet, pink and much spotted, was shown both by Messrs. Veitch and Messrs. Lee, and in both instances was commended. *Skimmia japonica vera*, from Mr. Standish, was awarded a first-class certificate; and last, but not least in importance, was the male *Aucuba japonica* in flower, the stamens and pollen being plainly visible in its small dusky flowers. Moreover, this was the first plant of the kind ever seen in flower in Europe, and its importance was, therefore, not overrated when it received a special certificate—a medal it should rather have been, as there can now be no doubt that we shall soon see the scarlet fruit of the female plants in abundance. The green-leaved *Aucuba*, or the original from which the variegated race has sprung, was also shown.

WHEN the dense yellow fog settled down on the west end of London on the morning of Wednesday last, after the promise of a bright and clear day, not a few said, "Ah! the old luck! If it does not rain, there must be fog when we have a show." Some there were more hopeful, who looked for a brighter afternoon, when the fires in London grates burnt bright, and the dense volumes of smoke had time to rise—and these latter were right. A beautiful day for the season of the year enticed out the gay and brilliant butterflies, and the gardens were well filled by a large number of Fellows and lovers of flowers. Several members of the Danish Royal family were present, and seemed much interested; while the Duchess of Cambridge and the Princess Mary, who are as regular attendants at the gardens as they are interested in the productions exhibited at the shows, were there also. The Royal party was conducted round the Exhibition and through the gardens by Sir Charles Dilke, the Rev. J. Dix, and Mr. G. Eyles.

Never was it more apparent, as observed by one of the correspondents of THE JOURNAL OF HORTICULTURE last week, how much the strength of these Exhibitions rests with the nurserymen. Had the productions of Messrs. Paul, Cutbush, Veitch, Lee, Smith, and Bull been taken away, verily there could have been little left; but the zeal and energy of these various firms contributed to make altogether a gay and brilliant assemblage. We could not but regret that the place again selected was the refreshment gallery. We saw some plants exhibited for the approval of the Floral Committee, which we should think would never recover the draught they experienced from the open door near which they were placed.

Although called the Camellia Show, it was the Hyacinths that formed the main feature of the Exhibition, and nothing could exceed the beauty of the long line of them exhibited.

Mr. Wm. Paul occupied the place hitherto held by Messrs. Cutbush & Son, who came second in the three classes, Mr. Paul standing first.

In the collection of six new and distinct varieties Mr. Paul had some very magnificent blooms, *Koh-i-Noor* being quite a model. There were in it besides, *Duc de Malakoff*, *Haydn*, *Florence Nightingale*, *Snowball*, and *Macaulay*. A still newer lot was shown by Mr. Cutbush, consisting of *Rouge Relatante*, red, semi-double; *Fair Maid* of Denmark, large white; *San Francisco*, a very fine semi-double, deeper in colour than *Ida*; *Prince of Orange*, pink, striped with carmine; *Feruk Khan*, dark blue; and *Maria Theresa*, pink, dark stripe. These were all novelties of 1863, but were not, perhaps, quite so large and fine in the bloom as Mr. Paul's.

In the class for eighteens, both Mr. Paul and Messrs. Cutbush had some very fine trusses. Amongst the former were *Haydn*, very large; *Koh-i-Noor*, a splendid spike; *Macaulay*, very fine; *Solfaterre*, large and good, novel, too, in colour—a sort of orange red. Mr. Cutbush had amongst his eighteen fine spikes of *Victoria Alexandrina*, white; *La Prophète*, pink-striped; *Ida*, fine yellow; *Florence Nightingale*, pink, with red stripe; and *Garrick*, fine blue, with a darker stripe of same colour. Amongst the 100 varieties contributed by each firm were some really magnificent blooms. Mr. Cutbush had *Van Humboldt*, dark red; *Johanna Christina*, light pink, carmine stripe; *Sir Bulwer Lytton*, white, large, and semi-double; *Duc de Malakoff*, orange, with red stripe; *La Nuit*, very dark; *Mammoth*, fine white; *Aurora*, orange yellow; *Madame Van der Hoop*, white; *Pieneman*, a large blue bell, but the bells are too far apart; *Reine des Jacinthes*, very fine; *Queen of the Netherlands*, good white; *Princess Clothilde*, dark pink; and *General Havelock*, very fine, dark. Amongst Mr. Paul's were *Aurora rutilans*, dark red; *Grand Lilas*, fine blue; *Aleda Jacoba*, yellow; *Cosmos*, late, and the spike somewhat too open; *Couronne de Celle*, blue, something like *Grand Lilas*; and *Mrs. Beecher Stowe*, pink, striped.

Messrs. Carstairs sent a nice lot of eighteen from Edinburgh, grown in small pots, for which a third prize was awarded.

In Tulips, Messrs. Cutbush was first with a very nice lot, of which the best were *Rouge Luisante*, *Vermilion Brilliant*, and *Thomas Moore*. The most favoured spot in the Exhibition was, however, that where the two boxes of Roses exhibited by the Messrs. Paul were placed, and an opportunity was afforded of seeing some of the new Roses of last season, especially in the box of Mr. William Paul. *Eugène Lebrun* was good, but eclipsed by *Olivier Delhomme* and *Charles Lefebvre*, two very bright and well-shaped flowers. *La Brillante* fully sustained its character for brightness, and *Robert Fortune* seems to be a "topper," very globular and lively in colour; but as far as fulness and size were concerned, they were all eclipsed by *John Hopper*, our new English Rose. We can testify to those who have not seen it (and the purchasers of it must comprise an extensive number, inasmuch as Mr. Ward had, up to the 1st of January, sold 2500 plants!) that it bids fair to realise all that I and others have said on its behalf. Mr. G. Paul had amongst his a fine bloom of a good dark *Prince Camille de Rohan*, *Clement Marot*, and a by-no-means-ugly bloom of *Reine des Violettes*, caught just at the right moment.

The tree *Mignonettes* deserved a prize for ugliness. Perhaps, like a *Skye Terrier*, it is in that their beauty consists; but never did we see a finer example of labour uselessly spent than in these. We would far rather have a sixpenny or ninepenny pot of this fragrant weed, such as one can purchase in Covent Garden, than the biggest and ugliest of the great plants.

There was a fine collection of *Amaryllis* from Messrs. Cutbush, of Highgate. The bulbs were as fine as could be well imagined, but the flowers were deficient in breadth of petal, giving them an open and loose appearance. *Eclatante* and *Howard* were amongst the best.

The Camellias disappointed me. The season had, I know, been a bad one—wood had not ripened last summer; but, notwithstanding, I had hoped that the prize of £10 would have brought together something better. The best flowers there were two of Mr. Standish's, not entered for competition—*Sarah Frost* and *Duchesse de Berri*. The largest were Mr. Veitch's, which obtained the prize. Amongst seedling flowers, there were some promising yearling *Cinerarias* from Messrs. Dobson, of Isleworth, and

Messrs. Smith, of Dulwich. Prince of Wales, a beautifully-shaped flower; Model of Perfection, very good, but not quite so large; and Princess of Wales were good; while Sunbeam, exhibited by Messrs. Smith, is very bright and promising. There was a pretty new Rhododendron, Romain de Smet, exhibited by the Messrs. Lee, of Hammersmith, and Mr. Veitch, of Chelsea; and Hebeclinium atro-rubens by Mr. A. Henderson, of Pine Apple Place, and Mr. Parker, of Tooting, is likely to be a useful spring-flowering plant. Mr. Henderson had also a pretty Epacris, Viscountess Hill; and Mr. Smith, of Dulwich, a nice little collection of Cyclamens, consisting of persicum and its red and spotted varieties.

I have left untouched the plants exhibited, nor have I given a nominal list of the florists' flowers, as these matters will fall to other hands; but I think one could not but see how superfluous the February Exhibition was, while, at the same time, such a Show as this tends very much to quicken the taste for early spring flowers.

The conservatory looked gay; but really there is such a thing as viewing everything in a *couleur de rose* tint, and spectacles of the most roseate hue must have been on your correspondent of last week who could see anything in the gardens. To me they seemed but little improved; while those abominations, the oil-cloth patterns of Mr. Nesfield, I heard unsparingly condemned on all hands.—D., Deal.

APRICOTS AND ORCHARD-HOUSES.

I CONFESS being much surprised at Mr. Rivers finding fault with my devoting a page and a half of No. 106 of THE JOURNAL OF HORTICULTURE to the management of the Apricot, when his own articles on his favourite orchard-houses might be measured by the dimensions of the houses themselves. To say the produce of his pen in that way is one hundredfold more voluminous than my unfortunate one on Apricots is speaking within the mark, so that the public may draw their own conclusions as to whom the term "voluminous" more particularly applies.

Mr. Rivers also says that all writers on gardening matters ought to be travelled men. Unfortunately those in private service cannot always make their travelling from place to place such a paying affair as a nurseryman can do; but, at the same time, the views they put forth are exempt from all interested motives. But as the direct reference Mr. Rivers makes to me compels my saying more of myself than I would have wished to do, I may say I believe there are only about half a dozen counties that I have never visited; while on the other hand, I have followed my calling in five counties of England, and these widely apart. I do not for one moment doubt but Mr. Rivers travels, and sees much more than I do, and I have read many of his articles with pleasure; at the same time I must say I should have liked them much better had his favourite theme usurped somewhat less space in the productions of his pen. Assuredly Mr. Rivers must have been joking when he called my article on the Apricot of one page and a half voluminous. Even his article in criticism of mine was half its length, without adducing anything fresh in the management, beyond condemning the idea of Apricots being grown against a north wall, which I happen to know was done by one of the most successful fruit-growers in the kingdom—one who, I believe, has taken as many prizes at the metropolitan shows as any man living.

Mr. Rivers says I have, "as usual," had a throw at orchard-houses. Now, on looking over the paragraph relating thereto on Apricot trees, the impartial public will, I believe, give me credit for dealing with that part of it with great delicacy. And more recent information confirms me that I spoke the feelings of nine-tenths of the fruit-growers in the kingdom. At the time I wrote it a letter from a friend was before me, detailing the unsuccessful attempt to grow Apricots under glass; and if Mr. Rivers had read the letter of "A CONSTANT READER," in No. 102 of THE JOURNAL OF HORTICULTURE, he would then have learned that there had been failures in Apricot-growing since 1829, as the writer says he had a fair crop on his open wall in 1861 and 1862 without any covering, while he had none in his orchard-house in 1861, and only three or four fruit in 1862. Surely this case required more of Mr. Rivers' attention than mine, especially as with the simple notice of Apricots not doing well under glass, I believe I have not more than incidentally mentioned orchard-houses for nearly two years; but even if I had, is not criticism legitimate?

Let us, however, take a fair view of the matter, and see what really has been done in the way of orchard-houses which has been so many years before the public. I will take the two broadest views that fruit is judged by—quality and quantity, and just compare what has been done in orchard-houses during the last twelve or twenty years with what has been done in the old-fashioned way.

Like many of your readers, I went to the great fruit show at Kensington in the beginning of October last, and was much pleased with what I saw. Amongst other things I was told there were upwards of two hundred entries of Pears, some of them of half a dozen and more dishes each, and there were twenty-one prizes awarded. Now, was it not fair to suppose that the mode said to produce the best fruit ought to have been represented in the prize list? but from inquiries I made at the time and since, I believe not one of these twenty-one prizes was given to orchard-house fruits. Now, I call this a fair test of the merits of the mode. There were some nice fruit on trees in pots exhibited, very creditable to the grower; but I think there were samples of the same kind of fruit grown in the ordinary way, quite as good, and certainly larger.

Now, as Pears are a favourite orchard-house fruit, why were none in the prize list? The answer is simple and conclusive enough. When orchard-house fruit-growers can beat those who have followed the old path it will be a very good time to vaunt their success. Hitherto (with, perhaps, one solitary case in a thousand), they have been "nowhere" in the race. It is needless saying anything about the quantity of fruit from orchard-houses: the letter of "A CONSTANT READER," page 186, could be repeated in many instances, only there is always a greater disinclination to record failures than successes.

Having a year or two ago given my opinion on orchard-houses, I may say I have seen nothing since but what confirms the views I then took of the matter. With trees planted out on a border of suitable soil, I have not the least doubt but most fruit trees may do well, and cause little trouble. Kept in pots they may occasionally do tolerably well, but with a vast amount of extra care and attention; and even with that, failures will occur. To say that a Peach will not succeed in a pot is more than I ever asserted; but I have never yet seen a fruit of that kind grown in a pot equal to the same grown in the ordinary way, and the results of fruit shows confirm my views; besides which, the term "fruit grown on trees in pots," must be accepted with caution. I have been anxious to see good Peaches in pots, and once took a journey of many miles to witness this result, and sure enough there was a fair good crop of fruit on trees in pots; but the said pots were as firmly fixed to the ground as the house itself. The roots, alive to one of Nature's laws more potent than any Mr. Rivers teaches, had gone in quest of that food intentionally denied them by the cultivator. To call such fruit "grown in pots" is a mockery.

I do not by any means doubt but that Mr. Rivers' trees are managed differently, but I have not seen them; nevertheless, I find there is a difference of opinion amongst those who have. But as Mr. Rivers says his greatest difficulty with Apricots has been in thinning the fruit, I am bound to believe him a very lucky man. By the columns of THE JOURNAL OF HORTICULTURE, there are others as well as myself who have yet much to learn on this matter; and although I have not read all the voluminous matter Mr. Rivers has written on orchard-house affairs, I have never read of orchard-house fruit beating at a fruit show that of the same kind grown in another way. At the same time, more light would be thrown on the matter, if all who have tried growing the larger kinds of fruit trees in pots would come forth and state the result of their practice, success, and failure. That there are several who have abandoned it owing to failure I have good proof; but as such people naturally shrink from avowing a failure in an enterprise they had previously advocated, it is not fair to urge them to come forward. This, however, need not prevent those who have been successful from recording their practice. For, be it remembered, that I do not deny the possibility of a good Peach being grown in an orchard-house; but I ask, Where was one grown in a pot equal to those grown elsewhere? and was any other opinion of its merits taken except that of the grower?

That it is quite possible to grow good Wheat, Barley, and Potatoes in pots I do not doubt, and "agricultural-houses" may be as fashionable hereafter as "orchard-houses" are now, the names bearing a strong resemblance; but I reckon the time is far distant when Mark Lane or Covent Garden will be in any

way influenced by the supplies from these sources. A dozen or more years have made no impression in the fruit trade; and when, as Mr. Rivers says, sturdy Oaks grow in flower-pots, will be a fitting time to look out for the other.—J. ROBSON.

GRAPES SHRIVELLING-UP WHEN IN BLOOM.

CAN you inform me the cause of my Grapes going off? My Dwarf Kidney Beans, you will find from the specimens, are affected in the same way—namely, all the blossom drops off.—K. B.

[We cannot speak quite decisively as to the cause of the misfortune, but in general such failures are the result of a check given to the system of the plant. Though you do not say so, yet we should judge from the length and consistence of the main stem of the incipient bunches, that the Vines are not deficient in vigour; but the flowers, instead of expanding, seem to have shrivelled-up and withered.

We recollect of a crop of Vines being lost from this cause, owing to a break-down of the heating apparatus at night during a severe frost in early forcing. There might have been some means resorted to to keep the frost out, if the accident had happened in the evening; but as it was, the bunches were frosted and never recovered, though the foliage suffered but little. There has hardly been frost enough this season thus to affect your Grapes, and therefore this could not be the cause. We believe that Vines set better when the temperature is pretty high even at night; but provided a good heat from sunlight is obtained during the day, a considerable decline at night will do but little harm. Contrary to all our general rules on the subject, we have several times had Vines in bloom as low as from 40° to 38°, and we did not consider they were at all injured. Of course, the heat was gradually raised during the day. Such a low temperature as that would not do for a continuance even at night; but, on the other hand, such a high temperature in darkness as 75°, and upwards, we consider to be more artificial than natural.

Once or twice we have seen bunches on a Vine affected as yours are from the explosion of a flue at night, or from the water in an open cistern being made to boil, either from a deficient supply of water, or from the flow being arrested whilst a strong fire was beneath the boiler, and the consequence was strong jets of steam or of water in a very hot state were thrown into the house, and scalding was the result; but as you do not say anything of the foliage being injured, we do not suppose that this happened in your case, though such occurrences are not uncommon in places where even the greatest and latest improvements in heating have been carried out. It matters not if one boiler heats a range of houses, and nothing more is wanted, besides tumbling-in a few barrowloads of fuel, than to regulate the taps and valves; for if this is not done, there may be burstings and explosions, even with the best-planned hot-water apparatus.

Sometimes when the wood is extra luxuriant and long-jointed, and has not been sufficiently ripened the previous autumn, somewhat similar examples will present themselves, but not exactly so; for in that case, when bunches do show, those that fail to come to perfection are apt to turn up and go off in tendril fashion at an earlier period than yours dropped their blossoms.

Again, over-excitement is apt to produce this effect, especially when there is a want of counteracting sunlight. Suppose we have a week or a fortnight of dull, cold weather, and the heat is kept up to 75° and 80° during the day, and from 70° to 75° at night, little air given, and plenty of moisture kept up in the house, the extra excitement produces a weakness in the constitution of the plant, and the most sensitive and valuable part is the first to suffer. We have seen such Vines, young bunches especially, after such dullness, closeness, and heat, hang weltering when the first sunny day came, when those with 10° or 15° lower temperature, and air also given, met the change from cloud to sunshine without any effect except apparent pleasure.

Whether any of these lesser causes have had any influence in your case you alone can determine, and we allude to them as much for the sake of some other inquirers as for your own individual case. Our opinion is that the falling of the flowers in your bunches is owing to a want of reciprocal action between the roots and the branches of the Vine. This may arise from the roots being placed deep in stagnant moisture, and, therefore, cold; or the roots may be near enough the surface, and yet wet

and cold, and, therefore, unable to meet the wants of the bunches in a high temperature within the house. But here you may say, If such were a cause, why did it not manifest itself sooner? why did the buds expand? why did the bunches show and look well, and then the flowers drop-off in this manner, instead of setting and swelling their fruit? Truly we can give no other reply than that the needed supply seems to fail at the most critical time, and that fruit under such circumstances will always suffer before leaves, though these and shoots too often feel the effects of such influence. If there is much of the stems of the Vines in the house, these would contain enough of elaborated sap to supply the bunches for some time; but if nothing fresh is obtained from the roots, there must come a period of exhaustion. The avoidance of such want of correlative action between the roots and branches must constitute the chief remedy. If the roots are very wet after this damp winter there would be no time to drain; but several rather deep pits or wells might be made in front of the border. If the border, inside or outside, were dry, then moisture and heat could easily be communicated by warm waterings. If the border were well drained, it could be forked on the surface, a little warm water added, and a covering of warm fermenting material placed over it; but if the roots are deep that will do no good. In such a case all that you can do is to prevent the border getting colder, and making it drier by litter-covering, unless when the sun shined, and reducing the temperature inside the house considerably, especially at night, that the plants may be less excited. You might also tie small weights to the points of the bunches—say bits of stone or lead, from a quarter to half an ounce in weight, and the strain thus given to the stem of the bunch will, we believe, entice more of the elaborated sap than would otherwise come to the bunch, and thus the fruit may be preserved. We see nothing more strange in this than the strength of the muscles in the arm of a blacksmith resulting from wielding the hammer. It would be needless applying such a remedy unless under such circumstances. Two years ago an enthusiast induced us to look at a viney where most of the bunches were threatening to become tendrils. By tying the weights on, and reducing the temperature until the roots were at work, a very fair crop was obtained. The border was well drained early in autumn, and covered with litter, and next season no such contrivances were necessary.

It would just be as well to examine and see if mice gnawing the stems were no cause of the disappointment, as they seem to have taken to Vines as a luxury this last winter.

You did not send any flowers of the Dwarf Kidney Beans, but the leaves did not convey any idea that they were suffering from a similar cause. The foliage was rusted, and had all the appearance of the plants having had too much water whilst the earth was cold. There were also marks of the small thrips—that is, where they had been, though we discovered none alive. The only remedy, if in fruit, is to gather this as soon as possible, and destroy the plants. If nearly in fruit, remove the worst leaves, fumigate with tobacco, and well syringe with clear soot water.—R. FISH.]

APRICOT TREES ON THE COTSWOLD HILLS.

I HAVE read the letters of both Mr. Robson and Mr. Rivers, and am thankful for what information they give.

I am inclined to think the rarefied air has much to do with the welfare of the Apricot, because this part of Oxfordshire, where the cottagers pay their rents with the proceeds of their Apricots, being on the end of the Cotswold Hills, has a very thin and bracing atmosphere. As Mr. Rivers says, the soil is oolite. But the oolite extends in a long narrow band from the south coast of England to Whitby in Yorkshire. One would like to know whether the Apricot would succeed equally well all along this band.

The oolite is rather elevated everywhere, so that it is hard to tell whether it be the elevation or the limy nature of the oolite. But if the tree grows in stiff loam very well the air may still have a great influence. Our unprotected trees have not suffered with all these frosts.—T. C. B., *Oxfordshire*.

GARDENERS' SOCIETY.

I HAVE before me your very valuable Journal of the 10th instant, containing the article by "G. A." I for one—and I only express the feelings of hundreds of the gardening community—was glad to see the subject of co-operation in gardening

brought before your readers. We must certainly interchange opinions and receive information from one another through the medium of your valuable Journal, yet still we are disunited as if we had no common interests to aid. We are unlike any other body of men in this, and, as "G. A." observes, we are each striving for his own aggrandisement irrespective of the results to our brothers of the spade. Surely, we could rise better were we to consult each other's welfare and work together in unity, which makes strength.

Shall we not, then, make as a body some response to "G. A.'s" propositions? I hope we shall, and I hope we are on the verge of some measures to the end we have to attain.

Could we not, as other professions and trades have done, join hand-in-hand to try to eradicate the existing evils which "G. A." mentions? Shall we not rally round the standard of the proposed Society, and, each putting his shoulder to the wheel, give a hearty strong push in the right direction and push the quacks, as the poet Hood says, "anywhere, anywhere, out of the world," at least out of the gardening world?

Surely, no one will doubt that we have men in our profession who are competent to effect such a union of purpose, and I do not doubt their willingness to take the management of such a Society could they be sure of the co-operation of the gardeners. Surely we are not so blinded to our own interests as to withhold our help from those who would be trying to help us; and that a Society of the character is very necessary must be obvious to all who, with an unprejudiced eye, will look at the proposal.

Who has not seen those whom "G. A." terms "utilitarians," when they have been with Dr. or Mr. So-and-So for a year or two as groom, gardener, cowman, and errand-boy creeping in as head-gardener? It is this false way of gardener-making that is ruining our profession. Not that I would try to keep these men from getting on and bettering their station in life—so far from it, that I would help them to attain it in a trustworthy way. Let them study and pass some such examination as "G. A." suggests before they are permitted to practise, and there is not one in ten who would then have to be allowed to practise.

Who has not seen many instances of the character just mentioned? I could give instances were they necessary, but every one with open eyes must have seen numbers of them; and yet they are placed on the same level as the person who has served an apprenticeship of seven or more years, and studied hard too.

Is it not surprising that gentlemen will employ such persons to take charge of valuable plants? yet they do it often. Surely, it is plain that a Society would be of great service both to masters and gardeners. The masters would then be sure of having a competent man and of good character; and if the proposal were explained to them, would surely come to our side and give us a helping hand to promote the interests of both, and we should take our stand in the world as a united instead of a divided body.

There are undoubtedly those who wish and looking-forward amongst the gardeners of England for some such Society to unite them and to protect them. I am glad to know that this is the case; and it is my opinion that, were a Society of the kind formed, they would with one accord support it, as they would be in duty bound to do. It cannot be expected that all will agree with "G. A.'s" proposition as to the government of the Society named, but his are merely hints he has been at the trouble to prepare and throw out. I certainly think the expenditure might be to a considerable extent reduced and thereby greatly bettered, for one of the points in the successful management of the Society would be to do it as economically as would be consistent with other points. But a committee of energetic men—and we have a great many in our profession—would soon surmount these matters, and every obstacle that would seem to prevent the formation of the Society proposed would vanish.—
A YOUNG GARDENER IN YORKSHIRE.

In your Number of the 10th there is a communication from a correspondent signing himself "G. A.," relative to the formation of a company, to be styled "The Company of Gardeners of Great Britain and Ireland."

All honour to him for being the first to introduce the subject; and although he may be rather sanguine, still I think the general outline of his plan is good; and as far as my humble means would allow (and I speak the sentiments of several gardeners of my acquaintance), I would give it my hearty support, for it is a want long felt by gardeners in this country.

There is, one thing I would like it better for, if it were more of a gardeners' than an employers' and amateurs' company.—
E. R., Cappoquin, Co. Waterford.

[There can be no question of the importance of the subject you allude to. The difficulty would be to find gardeners of sufficient standing, and with time at their disposal to work the Society up, so as to give it a fair start. We have every reason to believe that Mr. Fish and others you name, will have something to say on the subject. We know that though Mr. Fish looks on the whole scheme as somewhat over-sanguine and impracticable, that yet, like you, he is convinced that gardeners ought to do something of the kind to lessen those scenes of suffering and of destitution which are now so common when gardeners are laid aside by affliction, or are taken away when young, leaving families unprovided for, and for whom the Gardeners' Benevolent Society can do nothing. Before such a society in its more prominent features is organised, no respectable young gardener ought to take upon himself the responsibility of being the head of a family, without, by insurance or other means, making some provision for the day of affliction, and the probability of leaving young children behind him. The too-common carelessness shown in this respect is not creditable to gardeners in general.]

ROYAL HORTICULTURAL SOCIETY.

MARCH 18TH.

FLORAL COMMITTEE.—The Floral Committee held its meeting this day in conjunction with the second spring or the Camellia Exhibition of the Royal Horticultural Society at South Kensington. The plants placed before the Committee were neither numerous nor particularly novel and interesting. The most attractive plants were the two specimens of *Aucubas* sent by Mr. Standish, of Ascot; the one a female in flower of the green-leaved variety, till lately unknown in England, and introduced by Mr. Fortune from Japan; the other a small male plant in flower of the well-known variegated *Aucuba*, so common in all suburban gardens. The plant so well known to us is a female, and it is remarkable that the pollen-bearing plant has never before been brought into our country. We may now hope to see our old variegated friend under a new aspect, as Mr. Fortune informs us that under favourable circumstances it produces abundant scarlet berries, three times as large, and as brilliant as our common holly berries. These plants had been before the Committee on a previous occasion, and received their award. At this meeting a special certificate was voted for their being exhibited under such interesting circumstances. Mr. Standish also sent a plant of a new *Skimmia* in flower, which is supposed by some botanists to be the true *S. japonica*. Should that new variety produce an abundance of berries similar to the plant now known as *S. japonica* it will be a great acquisition. A first-class certificate was awarded.

Mr. Bull, of Chelsea, sent a new plant, *Pandanus elegantissimus*, a handsome-foliaged plant, with long, narrow, deep green, highly-polished leaves, edged with a brown margin, to which a first-class certificate was awarded. Mr. Bull also sent a new and interesting Fern, *Trichomanes spicatum*, which also received a first-class certificate. From the same firm were sent plants of *Alocasia picta*, *Nephelaphyllum cordatum*, *Fuchsia variegata*, a *Begonia*, and *Yucca Stokesii*; also three promising varieties of *Scarlet Pelargoniums*, but of which at this early period of the season no decisive opinion could be formed.

Mr. Turner sent two *Cinerarias*, one named John Spencer, which received a label of commendation, a very handsome, bright, showy, crimson variety, commended as a useful decorative plant. The other, named Mrs. Harley, was not considered an improvement on other varieties in cultivation.

Specimens of *Rhododendron Romain de Smet* were sent from Messrs. Lee, Hammersmith, and from Mr. Bull, Chelsea. A label of commendation was awarded to this plant as an early-flowering variety, with pale rosy lilac, profusely spotted flowers, but much resembling other well-known kinds.

Messrs. Lee also sent two *Camellias*—*Napoléon III.*, a delicate rose flower, shading to white, with well-cupped petals; to which was awarded a label of commendation. The other, *Jubilee rosea*, said to be a sport from *Napoléon III.*, with deeper-shaded flowers of the same colour, but inferior in form. From the same firm was sent also *Hebeclinium atro-rubens* and *cordatum*, large and coarse-foliaged plants producing heads of grey or

lavender-coloured flowers, somewhat resembling the *Ageratum*. These plants are of too robust a habit for general purposes, and would require a large conservatory to produce a good effect.

The Messrs. Smith, of Dulwich, sent a collection of *Cyclamens* of various shades of colour, also some well-grown plants of double pink and white *Primulas*. These were very beautiful, and decidedly an improvement, both in form and colour, on the semi-double flowers from which they were raised. A special certificate was awarded this interesting collection. A basket of small plants of *Azalea Flag of Truce*, a double white variety, was also sent by Messrs. Smith, and received a special certificate. This *Azalea* maintains its good character, and is not surpassed by any other double white variety, either for its purity or profusion of flowers.

A small plant of *Azalea Souvenir de Prince Albert* was sent by Mons. Verschaffelt, from Ghent. It will be remembered how highly this *Azalea* was spoken of at the *Azalea Exhibition, 1862*; it was then considered a first-class variety. The plant sent on this occasion, either from not being in condition, or from some other cause, disappointed those who had formed so favourable an opinion of it, neither colour nor form of flower at all resembled in quality those of the specimens exhibited last year.

Mr. Parker, of Tooting, sent a *Tropæolum* named *Vivid*. The plant was covered with flowers inferior both in form and colour to *Tropæolum Brilliant*. It may possess some merits from its tendency to early-flowering.

RATING OF NURSERYMEN'S GREENHOUSES, &c.

"I HAVE erected several hothouses and greenhouses employed solely for the purposes of supporting myself and family. Now the parish have just doubled my rates on the ground of the glass houses I have erected. Would it be asking too much for a reply as to whether this is lawful?—that is, whether the parish authorities can rate a nurseryman's glass houses to the poor's-rates, and, as he increases his buildings, rate additionally such buildings or not?—AN OLD SUBSCRIBER, G. R.

[We are of opinion that a nurseryman's greenhouses and his similar structures used exclusively in his trade are not rateable. We reprint the following from a former volume of our Journal:—

"A nurseryman rents a piece of ground, erects upon it greenhouses, and stocks it thoroughly. The parish then endeavours to rate him to the poor's-rate according to its improved value; and the question has arisen whether this higher rating is admissible. The question was brought before the Winchester bench of magistrates, and was decided by a majority that the higher rating is not maintainable. They held that greenhouses, unlike other buildings erected by tenants in other trades, do not attach to the land, but are always treated in law as stock in trade, which is clearly not rateable. What Lord Kenyon stated in *Penton v. Robart* (2 East 90), is so strongly in support of this view of the case, and is so illumined by that enlightened policy which should influence a decision upon this question, that we offer no excuse for its quotation:—

"The old cases upon this subject," said his lordship, "leaned to consider as realty (part of the freehold) whatever was annexed to the freehold by the occupier; but in modern times the leaning has always been the other way, in favour of the tenant, in support of the interests of trade, which is become the pillar of the state. What tenant will lay out his money in costly improvements of the land, if he must leave everything behind him which can be said to be annexed to it? Shall it be said that the great gardeners and nurserymen in the neighbourhood of this metropolis, who expend thousands of pounds in the erection of greenhouses, and hothouses, &c., are obliged to leave all these things behind them, when it is notorious that they are even permitted to remove trees, or such as are likely to become so, by the thousand, in the necessary course of their trade? If it were otherwise, the very object of their holding would be defeated. This is a description of property divided from the realty."

"Now, if a greenhouse be properly divided from the freehold, it cannot, in the case of a nurseryman, be anything but a part of his stock in trade, which, as we have already observed, is clearly not rateable. The bench were not unmindful of the recent decision in the *Queen v. Haslam* (Justice of the Peace, xv. 24); but they held, though not unanimously, that greenhouses being uniformly treated as part of a nurseryman's stock in trade, the present was distinguishable from that case."

Since the foregoing was written there has been a decision of the highest court of appeal in Scotland, determining that a nurseryman's greenhouses and hothouses are removable by him, being only part of his stock in trade. Now the poor's-rate is only

assessable upon the rent the land would let for, supposing all the stock in trade was removed. Such is our opinion; but you had better consult an attorney, and have your case placed before a barrister.]

FLUES VERSUS HOT WATER—VINES INJURED BY MICE.

I HAVE read with interest Mr. Robson's paper on the above, and I believe that we have not that advantage in hot water over flues which the extra expense should obtain. I have just such a house as Mr. Robson mentions, only wider. It is heated with a flue, and in it we grow Pines all the year; Vines up the rafters in summer; besides forcing a few Dwarf Kidney Beans, and a great many Ferns, hothouse plants, &c. They all appear to have good quarters, plenty of heat, and sufficient moisture. The flues are covered with tiles, which hold water on their tops. All our houses have flues in them, and we have no difficulty about heat.

I have had the management of houses heated with pipes for growing Pines, Vines, Peaches and plants; and here we have the same fruits growing, but heated with flues, and I see no disadvantage from them. Care is required with both, and experience before you can succeed.

Water thrown on hot flues is ruinous to everything, but especially to Grapes in bloom or when swelling. It will kill the bloom and spot the berries.

I beg to inform your worthy correspondent "R. F.," that he has not suffered alone, for my Vines have received just such treatment from mice as his own, only with me it occurred last year. About twelve months since, when I was making preparation for taking in my Vines (which are wintered outside, and the border was covered with fern), I saw that a young Vine, planted the season before, was out of its place. I took it in my hand to replace it, and to my surprise it was completely gnawed asunder. I took off the fern covering, and in so doing we caught the destructives, for there were, as is usual, a pair of mice.

Not satisfied with the destruction of one Vine, they had nibbled away all the bark from the old Vines close to the soil, but not very deeply, some part of the way around. I mixed together a good lump of clay and cowdung, put a thick plaster on the places gnawed, and let it remain on all the summer, and I believe it has done much towards the recovery of the Vines, for I perceive they are not suffering much now.—JAMES HARRIS, Gardener, Machen Rectory, near Newport, Monmouthshire.

DESTROYING WEEDS WITH OIL OF VITRIOL

AND GOOSEBERRY CATERPILLAR WITH WHITE HELLBORE.

I HAVE noticed the remarks in your Journal relative to the use of sulphuric acid for the destruction of weeds on walks; and having repeatedly seen it tried in the course of several years, can fully corroborate what has been advanced as to its excellence for that purpose, if the earth or gravel is not of a chalk or limestone formation.

The acid not only perfectly destroys the weeds, but assists in binding the gravel. Where chalk or lime about the acid is speedily neutralised, and the weeds soon re-appear; but where the soil is not of an alkaline character the effects of the acid are very permanent. A gutta percha watering-pot, being perfectly acid-proof, is far preferable to one of tin; for, as it is impossible to have the interior of the spout and rose protected with paint, these parts are speedily corroded in a metal watering-can.

If the acid and water are mixed in the watering-pot, seven parts of water to one of acid must be first introduced, or the heat evolved during the combination would probably make the gutta percha collapse. It is, perhaps, best to mix the two in a wooden tub, which will not sustain the slightest injury if the water is first put into it.

As the diluted acid not only changes the colour, but also in a few hours almost destroys the texture of cotton or linen fabrics, it should be used with caution. Woollen textures are not seriously affected; and although the colour is changed if spotted with the dilute acid, it will generally return if the material is dressed with a solution of carbonate of soda. The shoes may be effectually protected when using the acid by wearing goloshes, which are not in any way affected by it.

I tried white hellebore powder last summer as a remedy against the gooseberry caterpillar, and found it very efficacious. As soon as I perceived symptoms of the marauders on a tree, I lightly dusted it over with a little of the powder through a muslin bag. One dressing seemed to destroy all the caterpillars in existence at the time of its application.

N.B.—I was careful to obtain hellebore of the previous year's growth, and which had been quite recently powdered. Several persons tried it at my instigation, and it was always perfectly successful.—J. E. B.

HEATING A GREENHOUSE FROM A KITCHEN BOILER.

I HAVE just built a small greenhouse 9 by 6 feet. It is warmed by a four-inch pipe running round three sides and an inch pipe in front. I have connected these by inch pipes with the kitchen boiler about 20 feet off. The whole apparatus works properly, except that I cannot get heat enough—only about 14°—and that only by a most extravagant amount of firing. The boiler is an ordinary kitchen boiler, with a flue underneath and at the back, which, however, is of very little use, as it is difficult to clean-out. To increase the power of the boiler, a few bricks, or something of the sort, may be put inside to diminish the body of water in the boiler.—A CONSTANT READER.

[The diminishing the body of water in the boiler will be an advantage, and then enlarging the connecting-pipes a short distance might be managed with one-inch pipes, but in 20 feet much of the heat is lost before the house is reached. Were the pipes 3 inches, or even 2, it would be better. The pipes then should be packed either in sawdust or surrounded with a trough of wood and the end open into the house, so that the heat given off should have a free inlet there. If at the end near the boiler there were an opening to the external air, you would have a continuous supply of fresh heated air in the house. The flue at the back of the boiler should be kept clean.]

RHODODENDRON CULTURE.

WE have received the following letter from a correspondent, which, being of great interest to others similarly circumstanced, we insert, together with the remarks upon it by one of our regular contributors; but the subject is one which cannot be answered so ably as by those who have the good fortune to have ground, either natural or artificial, so well suited to the well-being of the Rhododendron as that of which our correspondent speaks. His communication runs thus:—

"I should be very glad if you, or any of your readers, could give me any information on the following points with regard to Rhododendrons:—The soil in the neighbourhood of my house is peculiarly favourable to the growth of these plants, which, indeed, sow themselves like weeds all about the place. For the last two or three years I have been raising a number of hybrids between some of the best-coloured of the ordinary crimson varieties, between Barclayanum, for instance (of which I have a magnificent specimen 20 feet high and as many through), Mrs. J. Waterer, Concessum, J. Waterer, and the like, with the idea of planting them in clumps along the road leading to my house. They are now growing so large and so numerous that I am anxious to place some of them at once in their destined positions, and with that idea to know whether, as a general rule, Rhododendron hybrids turn out well. I do not mean turn out new varieties, but handsome bloomers—superior, for instance, to the common ponticum or catawbiense. Hardihood, I believe, most of them possess. Breeding from hybrid varieties is, I am aware, often condemned; but more, I fancy, as producing weakly constitutions than deterioration of bloom. Mr. Standish remarks that nearly all his Gladiolus seedlings have produced handsome flowers. Is this the case with Rhododendrons?"

"Two years ago I tried to produce a hybrid between Rhododendron javanicum and a white catawbiense variety, but failed.

"I read last month in your pages with great interest Mr. Anderson Henry's letter regarding R. Nuttalli. I have several plants of that variety about 1½ foot high. How soon may they be expected to blossom? I fear they are not hardy, although with me the Azalea indica alba thrives and blooms magnificently out of doors, and as well as ever after the winter of 1860.

"I scarcely venture to put another question, which is this:

Are the Rhododendrons from the Neigherries, near Madras, of the same kind as the ordinary Rhododendron arboreum from the Himalayas, and are they moderately hardy? My brother, who sent me the seed some three years ago, was fully persuaded that they would prove hardy in favourable positions.—J. N. M."

[It is no easy matter to give advice in a case like the above, where the inquirer is evidently well qualified by experience to speak on many subjects himself; and favoured as he is by a situation so well adapted for the Rhododendron, and doubtless many other things, it almost excites one's envy to hear of these successes. However, we may say that our correspondent need not be in any fear from breeding from hybrids, for he is quite as likely to obtain good, useful, flowering varieties as if he confined himself to distinct species, and in all likelihood the progeny will be better than if the parents were widely dissimilar. The great object to be aimed at in such matters is to avoid the early-flowering ones, which rarely do well, and there are some varieties shy in flowering. These had better be omitted, unless they possess qualities of a kind worthy of being transmitted to some other plant. In regard to making new plantations of seedlings, it would in a general way be better to take them up and have them in a nursery for a year or two; but, assuming this to be done, there is no reason why your bed of hybrids should not be planted out at once into their permanent quarters. You must not expect them to flower in so small a state as plants raised from layer or grafting. Seedlings of all kinds are more robust than plants from cuttings, layers, or grafting, but they will flower all the stronger when they commence. Your soil must be very favourable for them, and the kinds you mention are good. It is not an easy matter to decide by appearances before flowering which are likely to turn out well; but, in a general way, those having small leaves like R. ponticum are rejected; while those with large and partly-reflexed foliage commonly represent the pale-coloured varieties; those favouring the scarlet breeds resembling, more or less, R. arboreum. These observations do not, however, hold good in every case, and it is only alluded to here as being likely to do so. Practice alone enables those daily amongst them to tell with tolerable certainty which are likely to turn out inferior, and these are, of course, rejected. Rhododendrons have, however, so much improved of late years in all the large nurseries that most of the seedlings sent out for the commonest purpose, as R. ponticum, have imbibed a tinge of the larger kinds and present larger and more varied hues, some being really very good.

In regard to the progeny of hybrids being delicate, there are certainly many exceptions; and, so far as I can give an opinion, it is only where the dissimilarity of the parents was very great that the offspring is sickly; and it is not to be wondered at that R. javanicum and R. catawbiense refused to breed, and, if they had, most likely the issue would have been sickly—much more so than the next generation from the said hybrid.

A good example of this was exhibited in Fuchsia Venus Vietrix, the first white variety of Fuchsia sent out. It was a weak grower, but subsequent seedlings from it possessed a stronger constitution, until the white ones of the present day are as robust as their darker brethren. It is, therefore, an error to suppose that hybrid seedlings are more delicate than their forerunners. Delicacy in constitution is only attained when the object aimed at by the hybridiser is the encouragement of the growth of a particular part of the plant that engenders disease. Thus, for instance, a variegated plant is in general more tender than a green one, and the improved vegetables of the Cabbage and other tribes are much less hardy than the weeds from which they originated.

It is very much to be feared that the widely different forms of the Sikkim Rhododendron will add but little to our shrubberies, excepting as objects of novelty, and many of their qualities are not desirable for out-door decoration. Mr. Cox, at Redleaf, has, we believe, established the hardihood of two or three species, but their appearance is not inviting. We shall, however, be glad to hear how you succeed with R. Nuttalli. To the best of our recollection, R. ciliatum, Russellianum, and another were the kinds that had been out of doors at Redleaf for a year or two, but they fell far short of the healthy and gay appearance the older varieties possessed. It is, however, possible, when their management becomes better known, that they may be turned to better account out of doors than they have yet been, and in favoured situations they are certainly worth the trial; and as the Indian Azaleas do so well out of doors with

the correspondent alluded to, we hope to hear of his success with other plants not usually regarded hardy.

With regard to the Rhododendron from the Neilgherry Hills, its hardihood or otherwise entirely depends on the altitude it was found at. Plants found at the base of these hills require stove heat in England, and midway up the greenhouse will do, and it is possible some of the extreme heights may furnish hardy plants; but as the Indian and Home Government have of late been at considerable expense in importing the Peruvian bark tree to this district, and a friend of the writer has gone to superintend a plantation of Coffee there, it is evident that in the district where these plants are cultivated—and both are destined for the Neilgherry Hills—Rhododendrons capable of withstanding the cold and changes of this country are out of the question. The greatest elevations must, therefore, be the only sites where hardy plants are found; and unless the severities of the cold season of their abode exceed those of an ordinary English winter, there is but faint hope of their doing well out of doors here; for, be it remembered, we have not the hot summer to ripen and perfect the wood which they have in India, so that it would not be prudent to trust more than a few plants to the rigour of an English winter until their hardihood has been in some measure confirmed. Taking into consideration the tropical heats of Madras, I should think the Neilgherry Hills do not attain sufficient altitude to furnish plants hardy enough to withstand the changes they are subjected to in England.—J. ROBSON.]

MESSRS. CUTBUSH'S HYACINTH SHOW.

THE annual Exhibition of Hyacinths at the Highgate Nurseries is one of those sights which no one should omit seeing. It has also the great advantage that one can inspect the floral beauties in quiet, and with a minuteness which is impossible at shows where the public are admitted in any number. Besides, the display of flowering-plants in the house in which the Show is held represents the decorative resources available at the season; and, from their number and excellent arrangement, they afford a good example of what a show-house may be made in skilful hands, and this with materials within the reach of persons with moderate means. Azaleas of various colours, Kalmias, *Dielytra spectabilis*, Acacias, Deutzias, Cinerarias, Cyclamens, early Tulips, &c., fill the whole of the back stage of the house, forming a dense mass of foliage and bloom, reaching nearly to the roof, and alike hiding stages and back wall.

It is, however, in Hyacinths more especially that Messrs. Cutbush possess an eminence, which is certainly surpassed by none; and this season their display of these attractive flowers is in no way inferior to that of last year. Added to this there are several attractive novelties which deserve attention. Where all the flowers are fine, it would be merely repetition to say in almost every instance fine spikes or fine bells. We shall, therefore, confine ourselves to giving a list of the names and colours of the best varieties. These were—

Double Reds.—Duke of Wellington, very pale rose, a large and splendid spike with bells closely arranged; Noble par Merite, deep rose; Koh-i-Noor, a very fine salmon; and Susanah Maria, salmon rose. Jenny Lind, deep rose; and Princess Royal, rose striped with pink, are also excellent.

Single Reds.—Solfaterre, bright orange scarlet; Von Schiller, deep salmon pink; and Victoria Alexandrina, a new crimson, are all splendid kinds, producing immense spikes. Macaulay, from its beautiful colour and size of bells, should be in every collection however small; and the following are also all of the highest excellence:—Amy, bright crimson; Cavaignac, salmon, striped with deep rose; Cosmos, rosy pink; Florence Nightingale, with large pale pink bells, striped with carmine; Howard, orange crimson; La Dame du Lac, pale rosy pink; La Prophète, pale pink striped with carmine; Lady Sale; Lina, crimson; Mrs. Beecher Stowe, deep rosy pink; Norma, delicate pink; Pelissier, a new crimson scarlet; Princess Charlotte, delicate rosy pink; Princess Clothilde, pale pink, striped with carmine; Queen Victoria, pale pink striped with red; Queen of Hyacinths and Robert Steiger, bright crimson. Aurora Rutlans, dark red; Belle Quirine, bright pink; Circe, salmon pink; Desdemona, dark crimson; Duchess of Richmond, dark red; Duke of Wellington, rose with carmine stripes; Johanna Christina; Madame Hodgson; Monsieur Feasch, pink; and Sultan's Favourite, rose striped with deep pink, can also be highly recommended.

Double Blues.—Garrick; Laurens Koster; Sir Colin Camp-

bell, light blue; Van Speyk, pale blue striped with dark blue are of the best. And Belle Mode, porcelain; Comte de St. Priest, light blue; General Antinck, pale blue; Paarlboot and Prins Van Saxe Weimar, dark blue, are likewise excellent.

Single Blues.—Argus, bright blue, with white eye; Baron Von Tuyl; Charles Dickens; Couronne de Celle, azure; Grand Lilas, and Orandates are the most choice. Bleu Mourant is also a very useful dark blue.

Double Whites.—Of these Sir Bulwer Lytton, cream, with a purple eye, is a splendid new variety. Cœur Noir, pale bluish; La Tour d'Auvergne; La Vestale, and Prince of Waterloo, are all excellent.

Single Whites.—Alba Maxima, pure white; Gigantea, deep bluish; Grandeur à Merveille; Madame Van der Hoop; Mont Blanc; Paix de l'Europe, and Snowball, are all of the highest excellence; the last-named in particular has the broadest segments of any Hyacinth known. The best of the others are Cleopatra, deep bluish; Elfrida, creamy bluish; Queen of the Netherlands, pure white, new and fine; Seraphine, pale bluish; Tubiflora, bluish, very large bells, stained on the outer side with purple; and Voltaire. Mirandoline is also a very good pure white.

Lilac and Mauve.—Of these Haydn and Prince of Wales take the first place; the former is of a splendid colour, and has a large spike. Dandy, bronzy lilac, is also good.

In *Blacks*, Othello is an excellent double; and of the single flowers General Havelock, of the deepest purple, is a splendid sort. La Nuit, Mimosa, Prince Albert, and Von Humboldt, deep purplish-black, are all first-rate.

In *Yellows*, Duc de Malakoff is new and very fine. Ida and Victor Hugo, are fine deep yellows. Aurora, pale straw, striped with pink, is also excellent.

Of the new varieties, Maria Theresa is a capital pale pink, with light carmine stripes. Prince of Orange, of a deep rose, with a bright crimson stripe up the centre of each petal, is a very fine double variety; and so is Rouge Eclatante, of a splendid deep crimson. Estella, another double red, is of a very delicate rose, with a narrow pink stripe up the centre of each petal. Fair Maid of Denmark is a most beautiful pure white, with immense bells; and San Francisco, a bright yellow, with a close spike, is a great acquisition in that colour. Feruk Khan has a very close, fine spike; the colour a dark violet purple. Pieneman, with very large porcelain blue bells, is also very fine. Lord Palmerston, a single bright blue, has a fine close spike; and Marie, deep blue, with an indigo stripe, is also good. Lamplighter, a purplish-black, with a very distinct white eye, appears a promising sort; but the spike which we saw was small, owing to the small size of the bulb which produced it. Probably another year it will improve in size, and if so the variety will prove an acquisition.

In addition to the Hyacinths, several very pretty varieties of early Tulips are also shown, as well as the collection of Amaryllids exhibited at Kensington.

We cannot do better than conclude by recommending our readers not to lose the opportunity of seeing Messrs. Cutbush's Exhibition, which will continue open till the end of the month.

METEOROLOGY OF CARDINGTON, BEDFORDSHIRE.

THE following table shows the monthly and annual fall of rain at Cardington in 1862, and the average during the last seventeen years. The greatest quantity was in 1848, 30.860 inches; and the smallest quantity in 1854, 16.245 inches: being 5.805 inches below the average of the seventeen years. The greatest monthly average fall is in October, July, and August; the least in February, March, and December; and the year ending December 31st, 1862, is 0.565 below the average:—

Month.	1862.	Average in 17 years.	Month.	1862.	Average in 17 years.
	Inches.	Inches.		Inches.	Inches.
January	1.350	1.661	August	1.820	2.337
February	0.320	1.089	September	2.310	1.880
March	3.115	1.300	October	2.410	2.624
April	2.110	1.704	November	0.980	1.634
May	2.750	1.969	December	1.250	1.419
June	1.810	2.064			
July	1.260	2.378	Total amount...	21.485	22.050

The following table shows the highest and the lowest readings

during the last seventeen years, of a self-registering thermometer at the height of 5 feet from the ground, and protected from radiation and rain; the highest readings of a self-registering maximum thermometer in the full rays of the sun, and the lowest readings of a self-registering minimum thermometer on the grass during the last thirteen years, and also the mean temperature, the number of days on which rain fell, and the quantity of rain of each year for seventeen years.

Years.	Maximum in Shade.	Minimum in Shade.	Maximum in Sun.	Minimum on Grass.	Mean Annual Temperature.	Number of days on which rain fell.	Rainfall in Inches.
	deg.	deg.	deg.	deg.			Inches.

—J. B. McLAREN, Observatory, Cardington, January, 1863.

RHODODENDRON GLAUCUM (GLAUCCUS-LEAVED RHODODENDRON).

Nat. ord., Ericacæ. Linn., Decandria Monogynia.—A small evergreen and very handsome shrub, of the average height of 2 feet, with branches of the size of a goose-quill. The leaves are oblong or broadly lanceolate, with a mucro, about 3 inches long, and 1½ inch broad, deep green above, and remarkably glaucous beneath. The umbels of seven or eight flowers grow from the ends of the branches, the flowers being a “pale pinkish-purple,” the tube campanulate, more than an inch long, and about as broad across the spreading limb of five rounded emarginate lobes. The whole plant has a powerful resinous smell. From Sikkim Himalaya, on the rocky depressed ridges of Chola, Lachen, and Lachoong, at an elevation of from 10 to 12,000 feet. Introduced, we presume, in 1850. Flowers in June.—(Gardener’s Magazine of Botany.)

HASSARD'S PORTABLE CHAIR.

THIS chair is one of the most complete of its kind ever invented, combining all the qualifications of portability, lightness, and great strength; and, from the ready manner in which it folds-up and the small space it occupies when folded, offers a great acquisition over the ordinary stools used as seats in gardens. For invalids it is invaluable, the back being a most useful and comfortable addition not generally met with in articles of this kind; and as there is no strain on any part of the chair, either when folded or not, it is almost, if not quite, impossible to break it. This has had practical proof in the original chair, which served as a camp chair for some years in the colonies, Turkey, and the Crimea, and can now be seen in as sound a state as when it started.

H.R.H. the Prince of Wales, in his late visit to Egypt, took several with him, and no complaints have been registered against

them. For horticultural fêtes its use would be invaluable, as the small space it occupies when folded enables its being easily carried, or it can be stowed away in a tool-house or other convenient building; and being made of wood, it possesses a lightness which the iron portable chairs do not.

Its uses are as follows:—1, As an ordinary chair; 2, With the back put down it makes an excellent table to a person sitting on the grass, as at a pic-nic; 3, It can be sat upon also when entirely folded-up; or, 4, makes a lounging chair if in this position the back only is put up.

Its price is only 12s. 6d., and its transformations so various that we should call it the *Protean Chair*. Major Hassard, the inventor, lives at Hilsa, near Portsmouth, and we have no doubt he would answer any relative inquiries.

Fig. 1. Shows the chair up.

Fig. 2. Folded on the ground.

Fig. 3. As a table.

Fig. 4. As a seat on the ground.

REMOVING A VINE LONG PLANTED IN A GREENHOUSE.

THE following is in answer to the questions of "F. S."

That you can remove this Vine without injuring it is not likely. If the Vine is very large and old-established, it is just as little likely that you can remove it with profit. If only a few years planted, and you resolve to do the job carefully, then the old Vine would be better than a young one. Without that care and trouble being expended, it would be best every way to let the old Vine alone and plant some fresh young ones, as their expense would be little more than that involved in moving the old one. These young Vines could not be expected to bear the first season. With proper care bestowed, the old one might do so and flourish well afterwards.

Though we can add nothing to what has been previously and lately stated, we will, to oblige you, answer your questions. And first as to soil. Good fresh soil of any kind will grow the Vine well. The chief point to secure is dryness by drainage. The best-flavoured, if not the largest, Grapes are obtained from districts and positions where there can be no stagnant water.

This dryness secured, the earth is a matter of less importance. A good loam, such as may be obtained from a roadside, will answer well. The soil that grows good vegetables and the common fruits will grow good Grapes. The fresh soil, if obtainable, is the best. That should be from 18 to 24 inches deep, and if outside the house it should slope to the sun. In late Numbers, and in another week or so, you will see much on border-making. The chief point, however, is to avoid stagnant water. The soil may have a tenth of its bulk of rough pieces of brick, and another tenth of fine brick and lime rubbish well blended together, and for every four cartloads of compost there may be a bushel of broken bones. Suppose the Vines are to be planted, the roots may be nicely spread out about 6 inches from the surface, and a little finer and richer soil strewed over them. Extra strength afterwards we would give by rich top-dressings and manure-waterings.

Now as to lifting your Vines. We wish you would have asked our advice any time between the end of September and

Christmas, as the chances would have been more in your favour. However, the fact that the buds will soon burst of themselves is not so much against you as at first sight would appear, as that will cause growth to take place all the sooner, and therefore you will only have to assist Nature in her operations. Not a day, therefore, should be lost. The first thing to do is to secure the head of the Vine and keep it as cool as possible. Then begin in front of the Vine-roots, and dig out a trench deeper than you expect the roots to reach. With a pick carefully pull down the soil and throw it behind you; and as you come to the roots save them, carefully tracing them right up to the bole or stem, and wrapping the roots as you disentangle them into cloths or mats, to keep the fibres you can save from being dried and killed by the cold air. This is no such difficult job as it would seem from our description to be.

Having taken up and removed the Vine to its place, the first object is to put the head into the desired position, and the second is to lay out and plant the roots. In such a case we would depart from the above simple mode of making a border, and 6 inches below the place we intended for the roots we would incorporate 2 or 3 inches of fresh horse-droppings if they could be found, so as to yield a mild gentle heat as well as enriching qualities. Place a couple of inches of fresh light soil over that compost, and on this lay out the roots regularly, packing them nicely, and cover with a couple of inches of soil. Then water moderately, so as to damp the roots, with water at about 140°, and as soon as settled cover with 5 inches more of soil. When that is done place 15 inches of hot fermenting material over the border, and, if possible, thatch the border, or use hurdles or cloth, to throw off the cold rains. If the job is thus done, a thermometer sunk 6 inches in the border would most likely show a temperature of from 75° to 80°, which would furnish a stimulus to root-action. The roots thus attended to, the next point is to keep the head of the Vine as cool as possible by moistening the head and keeping it shaded from the sun, so that roots may be forming in the border before the buds are much advanced. In this will consist the success. Without such care the old Vine had better be left alone.—R. FISH.

CAPE BULBS.

A CORRESPONDENT, writing from Liverpool, asks our advice on the management of the bulbs just received from the Cape of Good Hope:—*Antholyza præalta* (hardy); *Amaryllis revoluta*; *Agapanthus major* (greenhouse); *Albuca filifolia* (greenhouse); *Brunsvigia falcata* (greenhouse); *B. ciliaris* (greenhouse); *Calla æthiopica* (greenhouse); *Disa grandiflora* (greenhouse); *D. barbata*; *D. purpurea*; *Babiana rubra* (greenhouse); *B. purpurea* (greenhouse); *B. rubrocyanea* (greenhouse); *B. mixed*; *B. villosa* (greenhouse); *Gladiolus blandus*; *G. natalensis* (greenhouse); *G. hirsutus* (greenhouse); *Hemantus tigrinus*; *Hesperantha cinnamomea* (greenhouse); *Hypoxis flava*; *Geissorhiza rochensis*; *G. purpurea*; *Satyrium fragrans*; *S. cucullatum* (greenhouse); *Melanthium* (greenhouse); *Sparaxis* var.; *S. bicolor* (greenhouse); *S. purpurea*; *S. grandiflora* (greenhouse); *Ornithogalum caudatum* (greenhouse); *Ixia purpurea*; *I. ciliaris*; *I. var.*; *I. maculata* (greenhouse); *I. viridiflora* (greenhouse); *I. versicolor*; *I. flava* (greenhouse); *I. fragrans*; *Lachenalia purpurea* (greenhouse); *L. purpurea* var.; *L. alba*; *L. pendula* (greenhouse); *L. pendula* var.; *Trichonema cruciatum*; *Oxalis rosea* (greenhouse); *O. versicolor* (greenhouse); *O. alba major*; *O. alba minor*; *Nerine sarniensis* (greenhouse); *Tritonia crocata* (greenhouse); *T. fenestrata* (greenhouse); *Watsonia plantaginea* (greenhouse); *W. præcox*; *W. rosea major*; *W. rosea minor*; *W. Meriana*; *Morsea bicolor*; *Watsonia splendens*; *Wurmbea spicata*; *Anomatheca juncea* (greenhouse); *Babiana flava*; *B. plicata* (greenhouse); *Tritonia crispa* (greenhouse); *T. crispa* var.; *Lapeyrousia purpurea* (greenhouse); *Ornithogalum niveum* (greenhouse).

In reply to the inquiry of our correspondent, we may say that most of the *Ixias*, *Sparaxis*, and *Antholyzas* are hardy, and might be planted out into a warm border after being nursed awhile in a hotbed and then in a cold frame. This nursing in pots, we expect, will be necessary in order to compensate in some measure for the injuries sustained in the journey. Most of the other bulbs will require a greenhouse, especially such as the *Watsonias*, *Hemantus*, and others, that, iris-like, do not form ripened bulbs, the foliage never entirely dying down. Such bulbs as *Amaryllises*, *Oxalis*, &c., which ripen and

require a period of rest, will nevertheless benefit much by a considerable addition of heat at the growing time; for, though most of Cape plants will flourish and do pretty well in our greenhouses, most of them do better when subjected to the heat of the stove or hotbed at one time, and they will stand several degrees of frost at another. While, therefore, the bulbs are growing it would be better to keep them in a hotbed, removing them to a cooler place when they show flower; and when at rest they may be placed out of doors altogether. Those acquainted with the extremes of temperature experienced at the Cape will easily understand this. It would not, however, be advisable to suddenly subject bulbs and pseudo-bulbs recently unpacked after a long confinement to great heat. Rather let them be all potted in sandy peat, and placed first under a dark roof in a cool place, gradually increasing heat and light as the plants begin to grow.

FRUIT-TREE BORDERS CROPPED WITH VEGETABLES.

THE following inquiries relating to this very important subject being of a similar kind to many others we receive, we have called the attention of one of our regular correspondents to the matter, and subjoin his remarks, together with that of the querist, whose case is far from being an isolated one:—

"The garden in my charge is divided into four squares, with wire trellises round each square, on which are trained Apples, Pears, and Cherries, with a flower-border 5 feet wide between the trees and walk. Our wall-borders are 21 feet wide, with a fall of from 18 inches to 2½ feet, which are planted thus:—Half of south wall Peaches, the other half Pears; north wall, Plums; west wall, Cherries; east wall, Pears.

"The borders are entirely devoted to the growth of vegetables, except the west-wall border, which is under Strawberries.

"I think vegetables are highly injurious to trees, owing to spade-work being necessary in vegetable culture.

"I was thinking of planting two rows of fruit trees on each border—that is, Pears on the south and east, Plums on the north, and Cherries on the west, and training all on trellises having a fall to the walk, so that neither the front trellises would shade the back nor the back trellis would shade the wall trees; also, to have a flower-border in front to correspond with the other side of the walk. The fruit trees round the squares are upright espaliers about 5 feet high.—S. H."

[So far from your case being a solitary one of being obliged to crop your fruit-wall borders with vegetables, I firmly believe that ninety-nine out of every hundred are in the same predicament. That it is hurtful to the fruit trees I believe no one will deny; but the anxiety to have Peas a few days sooner, or a greater certainty of Cauliflowers standing the winter well, or to have Dwarf Kidney Beans in good time, or, in fact, the many things required by the household in sufficient abundance in season and out of season, induces us all to crop borders that ought to be left alone; and that very often to the permanent injury of the Peach and other trees, whose roots ought to have unmolested possession of the border. This, however, is one of those unfortunate choices between difficulties which occur in all callings, and is solved in accordance with the individual requirements of each place. If a crop of Potatoes, Peas a few days sooner, and the same with Cauliflowers, Lettuce, and the like be of importance equal to that of good Peaches and Nectarines, the preference given to the former must not be found fault with. If, however, fruit be most wanted, some sacrifice of the vegetables must be made, or a sort of compromise entered into. The last-named measure is that most generally adopted, although even in that vegetables are often allowed to usurp more than their just share of space, and our correspondent seems disposed to enter into a compromise when he suggests occupying the wall-border by trellises for training fruit trees of other kinds. In many cases, however, this would be objected to; and as vegetables must be had, it is the duty of the manager to contrive to injure the wall trees as little as possible in the endeavour to secure both fruit and vegetables. This is often done, care being taken not to crop the ground too heavily, and to manure accordingly. It is, however, better to allot a space of 6 feet from the wall to be kept free from all growth excepting that of the trees.

Our correspondent's plan of having a trellis for trained trees, instead of a vegetable-border, is not a new one. The late Mr.

Errington strongly urged it in many of his papers in the early Numbers of THE COTTAGE GARDENER; but he advocated a sort of table trellis. Arched trellises enclosing a walk exist in more places than one, and answer very well. The writer once had a sort of half-arched trellis overhanging the sunny side of a walk. This was also very successful; in fact, so obedient are most of the hardy fruits, that they can be made to assume almost any shape. Some of those already tried are as much to be admired for their novelty as their utility. However, I have no doubt that the roots of a Pear tree will do less injury to those of the Peach than the gross-feeding Cauliflower and similar vegetables; besides which, with only trees on the border, the necessity for digging deep does not exist; in fact, it is questionable whether it is necessary to dig at all or not. I once knew a gentleman—until very recently the oldest member of the Horticultural Society—who was so impressed with the propriety of letting the roots of such trees alone, that he had the Peach-tree border turfed over, and, I believe, it answered very well. Much, however, depends on the character of the soil and subsoil for the well-being of fruit trees, and there may be cases where a slight crop of vegetables, not deep-rooting, may do no harm. Healthy vigorous trees root much deeper than is generally supposed. Some men digging a well not far from whence I am writing are finding healthy useful roots at the depth of upwards of 28 feet! the soil being a sandy shale. The adjoining trees are Sycamore, Poplars, Fir, Birch, &c. The surface soil being good, these roots have not descended this depth for lack of substance near the top, but by their healthy appearance they have done so in consequence of relishing the nourishment met with there. When, therefore, the subsoil of a wall-border is one that suits the Peach and other trees planted thereon, a slight crop of vegetables does not do so much harm; but where the subsoil is of a contrary character, and the trees must thrive on the surface naturally or not at all, then by all means leave them the unlimited use of the latter, without any compromise whatever; and the condition of the trees, with other tokens, will alone enable the manager to determine how far this state of things bears on his case, and to act accordingly.—J. R.]

CINERARIA LEAVES INJURED.

I NOTICE an answer to one of your correspondents respecting his Cineraria leaves being injured. For his information (should this catch his eye), I beg to say that about the first week in January the frost was too sharp for me, and got into the greenhouse. In the morning, on going to look round, I observed the Fuchsia shoots looked very stiff. I gently tapped the pots of one or two of them, and the greater part of the shoots tumbled off; but the Cinerarias did not appear then to have suffered much. However, I noticed in the course of a fortnight that some of the plants did not grow at all, and others very little; while some did not seem affected in the least, and in a few more days the outer edges of the leaves appeared to be gradually mouldering and crumbling away, giving the plants, though nicely showing bloom, a very shabby appearance. Some of them are now all right again, but others have never recovered. I attribute this to their having been wetter than the others; consequently they felt the frost more than they would have done had they been dry.—AN AMATEUR.

THINNING BLOSSOM-BUDS OF FRUIT TREES.

I HAVE Peaches, Apricots, Nectarines, Plums, Cherries, Pears, &c., in a well-ventilated lean-to (south aspect) orchard-house in pots plunged in the borders. They are particularly full of bloom-buds, which, owing to the mildness of the late weather, began early in February to swell, and so water was given very moderately and gradually, and they were fast opening before the late change to cold. Some Pears of choice kinds are the only trees not repotted here last autumn. They came from London without balls of earth, and with the roots quite exposed; they were potted immediately, late in December, and are now crowded with bloom just showing the pink tinge.

It is quite impossible any of the above can bear one-tenth the blooms shown, and I wish to have your opinion as to the advisability of now removing them. My gardener says he would not touch one, but thin them after the setting. I recollect Mr. Rivers recommending thinning-out with sharp scissors fully one-half of Cherry-buds before they opened. If this be good prac-

tice, why not deal so with other kinds, especially in the case of the Pears I have mentioned, as it is very questionable how far the roots are established? My notion is that the merely moderate strength of a tree might be rendered of no avail in having to expend itself on such a vast quantity of bloom, though it would be equal to a very reduced quantity. Can any harm be done to the trees by my suggestion?—MANCHESTER.

[In the mere expanding of the blossoms there is little strength of the plant exhausted. We would, therefore, compromise the matter, and wait until the blossoms are so far opened as to show which have the strongest stalks, and the most prominent incipient young fruit; then, rejecting the smaller ones, thin more than half away. When these have set and have begun to swell kindly, then thin them out again, leaving about a dozen or so on each plant, or more, according to the strength. If you were sure of all the blossoms being fertile you might thin earlier; but even in the case of Cherries, many of the blossoms can never set, from imperfect organisation.]

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

PYCNOSTACHYS URTICIFOLIA (Nettle-leaved Pycnostachys).—*Nat. ord.*, Labiate. *Linn.*, Didynamia Gymnospermia. Native of Mount Zamba in tropical Africa. It has been found there at an elevation of 3000 feet, and will probably flourish in our greenhouses. Its flowers are dark blue, and appeared at Kew in January.—(*Bot. Mag.*, t. 5365.)

IMPATIENS BICOLOR (Two-coloured Balsam).—*Nat. ord.*, Balsamaceæ. *Linn.*, Pentandria Monogynia. Native of the island of Fernando at an altitude of 4000 feet. Flowers appeared in December at Kew; they have a white mouth and purple lip.—(*Ibid.*, t. 5366.)

MONOCHÆTUM HUMBOLDTIANUM (Humboldt's Monochætum).—*Nat. ord.*, Melastomaceæ. *Linn.*, Octandria Monogynia. Native of Caracas. Flowers in the stove in November and rather later. Flowers reddish-purple.—(*Ibid.*, t. 5367.)

WELWITSCHIA MIRABILIS (Wonderful Welwitschia).—*Nat. ord.*, Gnetaceæ. *Linn.*, Polygamia Monadelphia. Native of Damara and Cape Negro in western tropical Africa. This marvellous plant, it is said, sometimes measures 6 feet across the apex of the trunk, with ribbon leaves 2 and even 3 fathoms long. Mr. Anderson, the eminent African traveller, says:—"It is only found in one single locality—that is, as regards Damara Land, which locality is exceedingly circumscribed. It grows, moreover, in sandy places, and luxuriates when it can find a few stones where to fix its extraordinary tap root, penetrating often several feet deep, so that it is indeed a work of labour and patience to extract one single plant. I have been thus occupied more than an hour, and even then I have come away with only a portion of the root. The leaves attain a length of several feet, a small portion at the point only being withered; in other respects they are evergreen; they are straight-grained, and you can tear them from top to bottom without deviating a single line from a straight course. Rain rarely or never falls where this plant exists. I have crossed and recrossed Damara Land throughout its entire length and breadth, but only found the plant growing on that desperately arid flat, stretching far and wide, about Waalvisch Bay, or between the twenty-second and twenty-third degrees of south latitude. It is most common about the lower course of the river Swakop."—(*Ibid.*, tt. 5368, 5369.)

ROSE COMTESSE OUVAROFF.—This variety of the Tea-scented group was raised by M. Margottin. Colour, a soft creamy rose.—(*Floral Magazine*, pl. 137.)

PICOTEE JESSIE; CARNATION SAMUEL MORETON.—The first, raised by Mr. Turner, Slough, is a medium-edged purple. The Carnation was raised by Mr. Addis, but is in Mr. Turner's list. It is well and regularly marked.—(*Ibid.*, pl. 138.)

VERBENAS FLORA, ROSALIE, AND PURPLE EMPEROR.—*Flora*, crimson scarlet with white centre; *Rosalie*, reddish-purple, but crimson towards the centre, which is white; *Purple Emperor* is plum-coloured with white centre. They will all be let out by Messrs. Low & Son, of Clapton.—(*Ibid.*, pl. 139.)

THUNBERG'S TRICYRTIS (*Tricyrtis hirta*).—Sent by Mr. Fortune from Japan to Mr. Standish, who believes it will prove a hardy border plant. Flowers pearly white, thickly spotted with reddish-purple.—(*Ibid.*, pl. 140.)

VERBENAS—*Lord Leigh*, raised by Messrs. S. Perkins & Sons, Park Nursery, Coventry; crimson scarlet, yellow eye. Awarded a first-class certificate by the Floral Committee. *Lord Craven*, produced by Messrs. Downie, Laird, & Laing, of Sydenham and Edinburgh. "Decidedly the finest of purples."—(*Florist and Pomologist*, ii., 25.)

CHERRY—*Belle Agathe*, raised by Capt. Thiéry, of Haelen, Belgium. Of the Bigarreau character, but skin more red, flesh hard and crackling. Birds do not touch the fruit. Tree hardy and abundant bearer, ripening its fruit about the middle of September.—(*ibid.*, p. 32.)

NEW BOOK.

THE PHANTOM BOUQUET :

A Popular Treatise on the Art of Skeletonising Leaves and Seed-vessels, &c. By E. Parish, &c., Philadelphia.

THIS is well-named, for the embellishments are very beautiful and very disembodied, whilst the literary portion is equally phantom-like. There is nothing whatever new in it. The directions for skeletonising are merely the old one, requiring weeks and months for effecting the putrefaction of the pulp of the leaves under water. How old the process is may be learned from this extract.

"Some of the old London books we have lately forgotten to read give accounts of the identical process, and tell us that, as long ago as 1645, Marcus Aurelius Severinus, Professor of Anatomy and Surgery at Naples, turned his attention to the subject, and published a figure of a leaf thus delicately prepared. But this ingenious disciple of Æsculapius, according to the fashion of his time, kept the process a secret; and so we owe, probably, the first published account of the method of preparing plant-skeletons to a Dutch naturalist, Fredrick Ruysch by name, who in 1723 first gave to the world the announcement that, through the putrefactive fermentation promoted by warmth and moisture, the pulpy matter of the leaf may be loosened, so as to be separated from the fibrous skeleton, which may thus be preserved unimpaired."

We believe that a much shorter time might suffice to effect the skeletonising, and the process to attain this is worth trying to discover, for the results are beautiful, and, as Mr. Parish remarks, "adapted to embellish a home of taste."

NAMING HERBACEOUS PLANTS.

THE return of the early spring flowers reminds me of one of my gardening difficulties, which the Editors may kindly assist me in elucidating. I came into possession of an old place in the country a few years back, and amongst the many traces of the cultivated taste of my predecessor, not the least prized is the store of nice herbaceous plants which adorn the flower-borders of our small garden for the greater part of the year.

Having neither space, time, nor inclination to go into the modern bedding-out system, I would like to take stock, with the view of adding to my collection such noteworthy specimens as I might see from time to time noticed in your pages or otherwise; but the evil is that I am ignorant of the names, scientific as well as vulgar, of very many of those I possess. This I was forcibly reminded of not long ago, by ordering a lot and finding, as many came into flower, their duplicates already in the borders.

I thought I had hit upon an expedient last summer that would have thrown light upon my darkness. The principal foreman in the nursery from whence I occasionally procured a few florists' flowers, was a most intelligent, obliging fellow, thoroughly versed in horticulture, from his aristocratic titled favourites down to the little "Hyssop that springeth out of the wall," I assumed, judging from the discrimination he displayed, opening my eyes to the unseen distinctions between the "additional substance," "cleanness of club," "breadth of belt," "brightness of eye," &c., of this Pansy or that, or other florists' flower, second only to the style of your gifted Deal contributor. It was, therefore, with much confidence that I one day went off to town with a small bouquet as a first instalment, which I spread out on a frame-light before him, and stood note-book in hand ready to begin my list. Judge of my disappointment, taking up one after the other, with that curious puzzled look one could imagine in a geologist examining an antediluvian fossil, the only result

arrived at was, that in his opinion one of them "was some sort of Geranium." He, however, politely asked me to leave the flowers, and he would endeavour to get them named for me by some old gardener; but I fear the race of our good old "blue aprons" must be wearing out, as I have not heard from him since. I would, therefore, feel much obliged were you, or any contributor, to recommend any plain cheap old work on the subject, or otherwise kindly advise—TOWN-BRED.

FEATHERED HELPS IN A GARDEN.

I AM obliged by your insertion of my inquiry upon this subject, which shows that you deem the matter not unworthy of some attention; and I feel encouraged to put my own ideas into some more definite shape, more especially as I have since had an opportunity of asking the opinions of practical men on the Undercliff, from which place I am now writing. You will deal with my further remarks as you see fit.

I am afraid that no definite views are entertained by gardeners upon either branch of the question—either the domestication of birds for useful purposes in a garden, or the proper treatment of the race of small birds generally as wild. Upon the first point one gardener approves of gulls; another prefers the sandpiper, but that is, I believe, a migratory bird, and an attempt to keep it continually is, therefore, forced and unnatural; another likes the owl, as not only destroying mice, but anything else that can be picked up, and especially as working at night. Some think ducks would be useful upon special occasions and at special times. None like bantams, even Sebrights; and the habits of Guinea fowls, as non-scratchers, do not seem to have been noticed. Of course nobody ever dreamt that poultry in general could be "helps," as our Bristol friend assumes in his chapter of grievances. This, therefore, seems an open question; but upon the use of gulls I may mention that I have just seen a pair in a garden, and am assured by a medical friend, their owner, that, in addition to an unremitting attention to all vermin, one of them is as good as a watch-dog; for if an intruder finds his way into the garden at night, the bird screams, as long as he remains, loud enough to wake all the neighbourhood. But this part of the subject must depend upon local circumstances; for such birds may well be kept in small and enclosed gardens, when there would be difficulty in doing it in larger establishments. The principal question, therefore, is the proper treatment of the feathered tribe in general, and the views generally expressed by your correspondents show that it is a serious one. The views I have heard expressed are certainly in favour of birds, especially the soft-bills, as doing infinitely more good than harm, although requiring strict watching at particular times.

I rather think a true philosophy points to a protection of the race, accompanied by a complete control of their habits, in matters upon which our reason should guide their instinct. Do they not rank with the other inferior creatures which God has given for our help? Are they not all the year working for our benefit? Has the farmer or the gardener any cheaper labour than theirs? and is not the labourer worthy of his hire, in their case as well as in all others? We give our domestic animals extra food sometimes; we give our labourers extra wages at haytime and harvest; and why should not somewhat of the principle be extended to our birds? Are they not entitled to the food necessary for them? True, in the main they find it by living upon our insects; but if their want of intelligence leads them to be mischievous at seed-time and in a blossoming season, is not that a defect which our intellect should lead us to control rather than to visit the mistake with destruction? And, if when fruits are abundant they take their share, what more is it than pursuing the analogies of life? and what more is it than their right, always taking care they do not, in their want of knowledge of the properties of things, take too large or too wasteful a share? Surely it would be a great misfortune if the race were destroyed; and that is the logical sequence of the arguments against them. The race may be properly kept down like that of any other of the inferior animal creation when necessary, but that would be better done by a judicious bat-folding, when the hard-bills could be selected for puddings, and the soft-bills sent back to their work, rather than by a wholesale and indiscriminate slaughter.

I was yesterday walking through the grounds of a gentleman whose position in the scientific world entitles any opinion of his to profound respect, and who is, besides, an accomplished horti-

culturist, and possesses as fine a collection of out-door fruits, I should think, as any gentleman in England. I said to him, "How do you manage with the insect tribe with all your fruit?" His ready answer was, "Oh, I am very much in the habit of trusting to my friends the birds." "But do they not plunder you of a great deal?" "Well, of course they take their toll, possibly more than some people would like; but I am not at all sure that they take more than they have a right to," was his reply.

May not the question, then, be resolved into an adaptation of Loudon's advice as to Turnips and the turnip fly, "Sow enough for the fly and yourself too?" I think it may, and, without further argument, I have determined to try; and at the risk of being considered Utopian or anything else, and without heeding any amount of ridicule, I will give it a fair trial for at least a year, and will then report to you the result. I have a small garden here, containing a few dwarf standard Figs just coming into bearing (an immense temptation to birds), as well as good Jersey Pears, and other dwarf trees suitable for a small garden, and, contemplating a permanent residence here in the course of the summer, I am about to complete my stock both of top and bottom fruit, and I will make a point of increasing that stock so as to allow my birds 25 per cent., and will sow seeds in a like proportion. I will try hard to temper my fondness for the feathered tribe with a firm resolve to keep the 75 per cent. for myself and my friends, and I rather think the birds will have to rise early in the morning for their share.

I may add that I have bespoken a pair of gulls for day-labourers and an owl for night, and if I live the prescribed time I will carefully report the result of my efforts.—H.

I SCARCELY thought my experience, limited as it is to the practice of allowing ducks to range in my garden, was sufficiently extensive to be worth while recording in reply to your request for information on the use of feathered helps in a garden. But I see in your No. 191 a communication from R. Welch, Bristol, so thoroughly and completely condemning ducks, along with others of the feathered tribe, that I cannot refrain from saying that for several years past I have made it a rule to allow ducks, at various ages suitable to the season, to range at perfect liberty in my garden. I would not be without them on any account, but discrimination is required in admitting them. During the winter months—say from the first severe frost up to the end of February, or even into March, they may be admitted freely; after that time the old ones must be rigidly excluded, and may be allowed to run in the grass fields, where, during the breeding season, they do an immense amount of good.

So soon as you have ducklings they may run in the garden freely instead of their parents until they are five or six weeks old, but not longer; to be followed by others just hatched, up to the same age. This will bring you probably up to the end of May, or not later than the middle of June, when the flower-borders with young plants, together with the several crops of Strawberries and other fruits coming on, will require their exclusion also. Of course, where they are indiscriminately allowed to roam from one year's end to the other, they would carry death and destruction before them; but, admitted as I have instanced them, I aver that they are of inestimable value.

I first introduced ducks in consequence of the immense number of slugs and grubs with which I was troubled. These they have completely and effectually exterminated. A duck of any age will hunt out slugs and worms during the winter months. As soon as ever, or even before, the breeding season commences, they will consume every insect having life to be found in a garden. I have seen them eat up greedily the largest worms, cloaks, slugs, wireworms, and, indeed, as I said before, everything living—nothing comes wrong. The young ones, when introduced, limit themselves to worms and slugs, of which they are remarkably fond; and it is very pleasing to watch a whole brood of ducklings ranging the garden about a foot apart in regular marching order, and wheeling round and back again as soon as they reach the extremity. And, again, it is very amusing to see an old duck in the winter months range up alongside the Box-edgings, poking her bill wherever there is a chance of a slug harbouring, and then running off to the Strawberry plants, each of which will be examined in the same minute manner.

I introduced them originally from necessity, being a great lover of my garden. Having benefited by such introduction, I have long since formed a liking for them also, and I cannot re-

frain from thus recording the very great store I set upon them, although I feel that to do them full justice would require a, much abler pen than mine.—W. P. M.

WORK FOR THE WEEK.

KITCHEN GARDEN.

CLEAR-OFF all the old stumps of Coleworts, Savoy, Brussels Sprouts, Broccoli, &c., if not wanted for sprouts. This year up to this time there is no lack of winter Greens, and young Cabbages are forward and good. *Artichokes*, *Globe*, prepare a fresh plantation if necessary, by deep trenching and highly manuring the soil. *Asparagus*, forking the beds should be proceeded with. Some soot and salt may be sprinkled on them and forked-in. They are excellent stimulants when used in small quantities. *Beans*, make another sowing. The Longpod is a prolific sort; but the Green Windsor has the best appearance when sent to table. Earth-up the early crops. *Capsicums*, pot-off the young plants as soon as fit, and place them in a hot-bed frame; they are very subject to the green fly, which should be kept under by all means. *Carrots*, sow. The Early Horn is a good sort both for early and late use, as it keeps equally well with the long sorts, and is much better adapted for many soils than any of the others. *Celery*, prick out the early sown in boxes or on a slight hotbed. When it has taken fresh root-hold give it air at every favourable opportunity. *Jerusalem Artichokes*, if not yet planted no time should be lost in putting them in. *Kidney Beans*, make a sowing in pots. *Lettuce*, some of the best plants that have been wintered in frames may now be put out, some under a south wall and others in a more open situation. *Onions*, sow the main crops. If large ones are required, plant the very small bulbs of last year, or the autumn-sown plants in very rich ground; or large Onions can be had by the following method. Well tread the ground, and lay 3 inches of very rotten dung upon it; on this sow the seed, and cover with a little fine earth. *Peas*, stick the early crops as soon as they are earthed-up. A few small hornbeam boughs with the leaves on may be stuck on each side of the row. This will protect them from frost and cold winds. *Pot Herbs*, see that fresh beds of Thyme, Mint, Sage, Winter Savory, and other herbs are made. They generally want renewing every year. *Potatoes*, plant a good breadth of Flukes or any other good sorts. Protect Ash-leaved Kidneys and other early varieties as soon as they appear above ground. Sawdust is as good as anything, and it can be raked off as soon as all danger of frost is over. *Radishes*, sow for successional crops. The Turnip-rooted sort may now be sown. *Savoy*, make a good sowing of the Dwarf Green, which is the best for general purposes.

FLOWER GARDEN.

Complete any planting which circumstances compel you to do, but otherwise do not choose this season. Remember there is no time like early autumn. Prune Roses, and, as a general rule, the more severely you prune strong-growing Roses, the less they are likely to flower. If not done previously, the beds should have a good dressing of rotten dung or liquid manure. The Rose is a gross feeder. Complete the pruning and training of Clematises, Jasmines, Bignonias, and other creepers on trellises. Where you have gaps in Box-edgings insert pieces of Box to mend them. These may be clipped in April. Complete the boxing of beds and walks immediately; let the Box be trimmed neatly. Sweep and roll the lawns well, taking care that they are closely cut down now, thus laying a good foundation for the season. Nothing adds more to the beauty of a place than fine smooth turf; and where there is sufficient labour, it is a great improvement to extirpate Daisies, whose flowers mar the effect of a lawn very much. Retouch the grass edgings of the walks with all care and precision, and turn old or add new gravel where necessary, so that when your garden reaches the height of its beauty, all its parts may be in the most perfect order. Look over the beds planted with bulbs, and where necessary stir the surface soil so as to keep it open and friable, and also to give it a clean, neat, fresh appearance.

FRUIT GARDEN.

Finish the nailing of all wall trees. Tie down the branches before the buds swell too far, of the Pear trees trained *en quenouille*. Protect blossoms with canvas, bunting, fir boughs, or fronds of Ferns. The covers may be taken off occasionally on sunny days, and put on at night when frost is expected.

STOVE.

Push *Clerodendrons*, *Stephanotis*, and *Allamandas* forward as briskly as possible, but do not be in a hurry to train them. Pot-off the *Achimenes*, and any seedling plants which are sufficiently large, and start a fresh lot of *Achimenes*, *Gloxinias*, &c., to form the second succession. Stimulate the young growing plants as much as possible—that is, consistently with the state of the weather; and while you give plenty of air, at all times guard against sudden changes and cold winds. All Orchids that have commenced growing and require potting, should be attended to forthwith. This is a good time to shake out and repot *Cyrtopodiums* and *Sobralias*; they thrive best in good-sized pots, well drained, in a compost of equal parts of good turfy peat, loam, leaf mould, crocks and charcoal broken rather small mixed well together, and when the plants are growing freely, they must be well supplied with water. Pot in the same compost, omitting the loam, the following genera—*Houlletia*, *Acanthophippium*, *Mormodes*, *Lycaste*, *Cycnoches*, *Catasetum*, and *Huntleya*. This is also the best time for parting and shifting *Gongoras*, *Brassias*, and *Acroperas*, they succeed well either in baskets or pots, and should be potted rather high in sphagnum moss with a few large lumps of charcoal built in amongst it in the process of potting, and all made fast with a few rough deal pegs.

GREENHOUSE AND CONSERVATORY.

Where a large quantity of hardy shrubs is annually forced, either to decorate the drawing-room or conservatory, it is not desirable to pot a fresh stock each season, as a number of deciduous shrubs—such as *Roses*, *Lilacs*, *Honeysuckles*, &c., may, by proper treatment, be made to bloom for several successive seasons. Select, therefore, the most suitable plants when removed from the houses, and give them some kind of temporary shelter to gradually harden their foliage. Those cramped for pot-room, shift into a size larger, pot in rich turfy loam, and towards the middle of next month plunge them in an open situation in order that the wood may be ripe early. These plants from having been previously forced will bloom earlier than the new stock, of which a portion each year should be potted to replace such plants as become useless for further work. Now is a good time to commence with a stock of *Begonias* for next season's display. As they go out of bloom allow them a short rest in a rather dry house, when they may be partially disrooted, pruning-in any straggling shoots. Keep them close and syringe frequently, when they will soon commence growing. Abundance of light and a tolerable share of pot-room are necessary to insure fine plants.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

PUT-IN the bulk of the Potatoes on dry days, using the ridged-up ground for the purpose, planting the Potatoes in the hollows, and trundling-in the nice mellow soil of the ridges over them, after they had been covered slightly with material from the burnt earth and charring-heap. Placed some of the most forward sprung ones on a north border, covered them with leaf mould and then with litter; to be lifted again when we can find room, and to be placed over a mild heat from tree leaves, as we fear we have not enough of forward ones, and cannot spare a bit of glass or cloth for a fortnight. Those tubers planted in pots are now yielding a nice supply for the table.

Prepared ground for Onions, Leeks, &c., and for sowing spring vegetable seeds. Would like to have the ground mellow and warmer before sowing. In light soils this will be of less importance, and sowing may be proceeded with. Hoed over Asparagus and Sea-kale beds, so as to kill any weeds that might be coming, before giving a dressing of salt. Threw rough ashes, sawdust, and barley awns over Peas and Beans coming up. Will move the Peas shortly to the orchard-house. A row of Tom Thumb in front of one house is looking very strong and sturdy; but this Pea, though early, has little except its dwarfness and earliness to recommend it. How one of our esteemed coadjutors could sigh after the miserable small Peas that come in first, as the Sangster's and the Frames, and wish for their tasteless produce all the summer through, we cannot imagine; but, of course, he ought to please himself, and can easily do so by sowing only those small kinds often enough in succession. We think we mentioned long ago that we once were brought to book for sending old Peas to table—considered old because no one had the courage to taste them owing to their size, the Peas being fine specimens of Jeyes' Wonderful, as soft

as butter in the dog-days, but larger than Charltons when full grown, and then requiring some masticatory powers to fit them for digestion. In most small places an error is made of sowing too thickly. If the Peas were a couple of inches apart the crop would generally be more abundant; but the mice and the birds are so apt to help themselves, that in self-defence we often sow thicker, but with no great advantage. A magnificent row of Parsley in an orchard-house we must get rid of, as it is not wanted this season. Such a crop would have been worth much in 1861, and most likely we will try the same plan again. The seeds were sown at the end of June close to a row of Dwarf Kidney Beans, then bearing. By the time the Parsley was any size the Beans were removed. Parsley out of doors has needed no protection this season. Some of this Parsley will be stuck in thickly in a border for roots, as those of the common kind answer for stewing, &c., nearly as well as the Hamburg. Those who save their own seed should now mark-out some of the finest plants having compact curled leaves.

FRUIT GARDEN.

Netted some dwarf Plum trees that were a mass of fruit-buds. These trees had been well syringed with the mixture of water, soot, lime, and crowding, and the birds had let them alone until they had it all to themselves during the stillness of last Sabbath morning, then they pretty well stripped several of the trees; and it was not what they ate of the buds, so much as the numbers they nipped-off and threw down in sheer wantonness, that was the most vexing part of the affair. We know that many of the extra advocates of the little birds are so steeped in philosophic wisdom and endurance, that hardly anything conceivable could ruffle their mild well-governed spirits; and yet we think that such sights would be apt to move their choler a little, and that even they, if their favourite fruit trees were near to well-kept preserves, would acknowledge that it was possible to have too much of a good thing.

Finished pruning and nailing Peaches and Apricots out of doors. Find in the latter still traces of the frost of 1860 and 1861, in shoots and branches dying-out in places, and some kinds are not so well covered with bloom-buds as we should have expected. Watered the borders in orchard-houses, and set out and fresh-dressed the surface of trees in pots. Our house is a lean-to, with a walk near the back. We want a trellis of wood or iron for this, but have not obtained it as yet; but it looms in the future. The walk being formed of a sprinkling of gravel and sand on the surface, with an edging of brick on edge, looks well enough, but it becomes so hard and firm-set, that no water will penetrate; and when we break it up to give a good soaking, no person careful about his shoes can walk on it for some time afterwards. We incline to think that a cast-iron trellis in pieces some 9 feet long, and 15 or 18 inches wide, would be the best thing for such a purpose, where neatness and ultimate economy are considered. Our sand-and-gravel path would be the cheapest at first, but if not attended to, the soil beneath is apt to become too dry. In the meantime, having given the space thus covered a good soaking with manure water, doing it by degrees, we shall prevent the necessity of breaking-up the path often, by frequent, daily sprinklings on the surface of this pathway part, and that will so far prevent free evaporation from the hard surface. A trellis would allow of air and moisture penetrating freely.

The trees which are not yet all regulated, and which must now remain so until they are set, are as thick of bloom as they can bear. Had we time we would thin freely, for if a fruit is allowed to remain for thirty or forty blooms, it will be pretty well enough. Some people like small Peaches for tartlets, and a few may remain for that purpose before the final thinning. We do not know why, but we never knew Nectarines when young used for that purpose; but many people like Peaches as well as green Apricots. Young Grapes are also very nice, when not larger than small lead shot. When the young berries are as large, or larger than frame Peas, you would require to be on good terms with a grocer to render them palatable. When very young they are free from such extreme acidity.

Smoked the Peach-houses again for the brown beetle, which came to us last year as no common visitation, and how we cannot say. We went to bed on Saturday night, glad to think that, having been over all the trees and found none, we had succeeded in driving the ugly customer away. We took the opportunity of watering the borders of the house pretty well with chilled water, and then, having well syringed the trees before shutting the house up, we congratulated ourselves that this torment was

disposed of for a time at least. On Monday forenoon some of the lower shoots of the Peaches were as black with the enemy as if you had dusted them with charcoal dust. No doubt they had been enjoying themselves among the dry nodules of soil, had sallied out to escape the watering, and, finding the foliage sweet and fresh after our extra syringing, had resolved on having some of the best that was going. There is little difficulty in killing them by smoking, by washing with Gishurst, or other things, as a slight touch will kill; but if the touch be slight it will only set free prematurely a batch of young ones, or if one beetle escape you will soon have hundreds. If you take a good fat full-grown one—say as big as a good-sized turnip seed, and give it a squeeze with the point of your nail, or the point of a small stick, you will cause to emerge a string of young ones more or less fully formed, looking under a microscope like a rope of Onions. The myriads thus quickly produced by one insect are incalculable. On the wall-plate of a pit in a sunny day we found some running about, but have seen none since the frost. Whenever one is seen it ought, therefore, to be hunted-up; and when none are suspected, the trees, when the fruit is set, should be syringed over now and then with clear Gishurst water, clear laurel water, and clear soot and sulphur water, so that the leaves may not present such a tempting bait for them. A little of these precautions will often keep them off altogether. We found last year a beetle very similar covering entirely some plants of Horseradish; but they did not seem to care for other plants or leaves placed beside them. This one that has troubled us a little with the Peaches is very quiet and lazy during the day, but he can run about fast enough at night. If allowed their way they will soon suck all the virtue out of a shoot. If not eradicated or destroyed in summer, our experience would give us little hopes of getting rid of them by any means in winter: we question if even a severe frost would kill them—they would find means for sheltering themselves.

Proceeded with other houses much as detailed in the last and previous weeks, attending to setting Grapes, training Cucumbers, potting Melons, regulating and changing Strawberries, which are showing their gratitude for the fine sunny days.

ORNAMENTAL DEPARTMENT.

Out of doors the work much the same as in previous week. Shifting plants, and being smothered-up for want of space, we have turned out into earth-beds some thousands of bedding plants, beginning with Salvias and Calceolarias, and will follow with Geraniums and Verbenas. These, according to the size of the plants, will have an average space of 3 or 4 inches, so that they may turn out nice bushy plants in May. They will be protected from cold weather chiefly at night by whatever can be most conveniently obtained. Nothing is better than a roll of calico fixed to poles. Proceeded with making cuttings of bedding plants as room could be found for them, pricking-off Lobelias, and sowing flower-seeds in pots in heat, deferring others a little longer, &c.—R. F.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

PACKING PLANTS FOR NEW ZEALAND (A Lady).—From May to July is the best planting time there; so not a day should be lost in despatching them. Moss or damp cocoa-nut fibre dust packed closely round deciduous trees, and in a common wooden box fastened round with iron hoops would preserve them as well as any other mode. We cannot say where you can buy Hepatica or Clematis azurea grandiflora seed.

GOURDS (F. S.).—Such Gourds as Big Ben of Westminster, Dr. Lindley, Goblet, &c., grow large; but for the front of a house we would prefer a heavy crop of a less size. About removing your Vine, see another part of our columns.

WORMS IN THE SOIL OF A LAWN (R. C.).—No mode of banishing them is more effectual than watering the lawn once a-week with lime-water.

COKE AS FUEL.—CONSUMING SMOKE (J. Mackenzie).—We think good coke is cheaper than coal; but yours ought to be good at the money. The most obvious means of lessening the smoke, if coal is used, is to introduce a small pipe, say from half to three-quarters inch wide, communicating with the external air, just in front of the fireplace, which will throw the smoke back on the fire again. A small hole in the furnace door near the bottom is also useful. A simple mode is to keep the live coal at the neck of the furnace and the fresh nearest the furnace door, and shove it along as it burns. The smoke will thus be burned as it passes over the live fuel, and what is behind will be gradually coked. We have several times found that in boiler furnaces a plate inserted below the damper for sweeping the flue, with a hole of a quarter of an inch in its centre, did much to lessen the smoke, especially when the damper was partially in.

PROPOSED FLOWER PLANTING (Godetia).—As you want the plants in your beds to bloom at the same time, to be of the same height, and to present an equal mass of bloom with *Nemophila insignis*, then we would so far alter your proposed planting as thus, beginning with *Roses* at summer-house:—*Mignonette*; *Nemophila*, blue; *Eschscholtzia tenuifolia*, light yellow; *Saponaria calabrica*, bright rosy pink; *Sweet Alyssum*, or *White Nemophila*; *Nolana paradoxa violacea*, or prostrata, blue; *Mignonette*. The *Convolvulus minor* would be too rampant, and in damp seasons too green, and in the afternoons too dull. The narrow beds will look as well without divisions, the plants being allowed to touch each other. A nice ribbon in lines might also be formed of such a border. 20 by 7 feet, and then the border might slope, from having the tallest lines at the back. The *Godetias* of which you are so fond will do very well for the crosses. On one side we would sow or use *roseo-alba*, and on the other side *rubi-cunda* or *Lindleyana*. All these will bloom long if you pick off the flower-seeds and water in dry weather.

PRUNING ORANGE TREES (E.).—Very seldom, indeed, do Orange or Lemon trees require any pruning, unless they become diseased, when they may be cut back to a limited extent; or, if trained against a wall, they will occasionally want a fore shoot taken away. But when grown as bushes or trees they seldom need the knife, unless they encroach on the pathway, against the glass, or in some way or other usurp more than their allotted space, when they may be cut back by taking out some of the most offending branches, avoiding by all means giving a clipped appearance. About three weeks or a month before the season's growth commences is the best time to cut them, when they speedily recover and conceal the mutilation.

PEACH TREES IN A HOUSE WITHOUT FIRE HEAT (D. P. B.).—Your trees which are in flower will only require plenty of air until the bloom sets, when they may be syringed; and as it is not unlikely that green fly may make its appearance, a gentle fumigating once or twice with tobacco will be required about the time the fruit is setting. Disbudding may commence, but this must not be all done at once, but by degrees. The amount of water given must be regulated by the dryness or otherwise of the site. Generally speaking, deluges of cold spring water are bad; and as you say your trees are planted against the front of the house, it is likely a great part of their roots run outwards, and consequently those inside will require less water. We should hardly think your house in the north of Northumberland would be altogether safe without fire heat from some of the severe frosts now and then occurring in some seasons; but you may guard against this by covering the glass with mats, or something of that kind. After the fruit is set you may syringe the trees every morning, using rain water for the purpose.

DISA FROM THE CAPE (Frank).—The species named by you—viz., *Disa grandiflora*, *barbata*, *purpurea*, *rubra*, *culcullata*, and *fragrans*, are not all known to us—in fact, so much uncertainty of late years has arisen in the nomenclature of Orchids of this class, that it is probable some of the species you have received may exist under another name. Your best way is first to treat them as greenhouse bulbs, and after they begin to grow to increase the heat to that of the stove. If they be in masses of several bulbs together that will easily part, separate them at once, but do not tear off a half-formed offset until it be sufficiently advanced to part easily from the parent root. We shall be glad to hear how you succeed with them. Cape bulbs, once very popular, have been neglected for many years, but are again taking their proper place in public opinion.

CUTTING-IN EVERGREENS (A Subscriber).—March and April are the best months for pruning them, as the shrubs speedily afterwards make new growth, and recover the unsightly mutilation. They may be cut-in at any time during the winter; but for the reasons above given, we have always preferred delaying it until a short time before they started to grow. It is not advisable to cut all the foliage away; leave a branch or two on for a time, even if they be cut off hereafter, as they encourage the growth of the new shoots.

GREASY LIQUOR (T. H., Reigate).—Apply it to any part of the soil where Cabbageworms are to be grown.

TEMPORARY EDGING PLANTS FOR A KITCHEN GARDEN (G. Graham).—Beet, as you propose, will do; but we should prefer Parsley, or say a part of both with a little Thyme also if wanted. Having 500 yards altogether, we should say it would be better not to have it all of one kind. One ounce of Beet seed will sow 100 yards; but as the seed is not expensive, it is better to sow more than that quantity of seed on the space. Beet bears transplanting very well, and it is advisable at all times to sow a little on some favoured spot to fill up gaps in the general plantation.

KOHL RABI AND MANGOLD (Idem).—About 4 or 5 lbs. of seed of the first per acre is a fair allowance; the other is a large seed and may take double that quantity; but, in seeds that are inexpensive, and when the quantity of ground is small, it is better not to pinch seed. Sow a little of both in some favoured corner at the same time as you sow your main crop, so as to have plants to fill up gaps, &c.

ROSE TREES AND BONE MANURE (Subscriber).—If the worms which are attracted by the bones seize also upon the roots of your newly-planted Rose trees, then by all means take these up and replant them in fresh soil without the bones, allowing the latter to lie exposed to the air if possible to kill the vermin. If, however, the worms only attack the bones, no particular harm is done; and if other conditions are favourable the Rose trees will come all right. If, however, the bark of the roots is eaten away, no time must be lost in removing them, washing their roots well in lime water to efface all traces of the pest before planting them in their future situation. We are not sure what you mean by the term "worms."

JAMAICA FERNS (P. B.).—If you procured some botanist to name the specimens, your best plan then would be to advertise the collection for sale.

HEATH CUTTINGS—HEATHS IN SUMMER (Tyro).—Heath cuttings must be regularly watered as they need it: soaking them well will kill them. The glasses must be kept on until roots are formed, and then be taken off by degrees, leaving them off at night first, then morning and evening in addition, and then removing them altogether. Heath bloomed in winter, if at all free-growing, should be pruned pretty well back, kept close until fresh growth is proceeding freely, then more air given, and be fully exposed in autumn to the sun and air, and be housed in October.

APRICOT IN A GREENHOUSE (T. Wood).—If you keep your greenhouse warm in winter, or if you have a stage so as to shade the back wall, your Apricot tree will do no good as to fruiting. If you merely keep frost out in winter, have no stage which would shade the back wall, and give plenty of air in spring—then the tree will do well. From your description, however, we suspect the tree wants root-pruning. If you gave as much heat to your greenhouse as from 40° to 45° in winter, and kept it rather close in the spring, a Peach or Vine would do better than an Apricot. We would not despair of the Pear trees for next season, if you follow the same system, though we are almost afraid you have missed some of the main tap roots.

ORCHIDS (Orchidophilus).—For a bulb of *Calanthe vestita* from 2 to 3 inches would be a good size. It is somewhat difficult to renovate a neglected collection. They will require more shade, and more moisture in the atmosphere than healthy specimens; and as soon as they are moving strength may be communicated by manure-waterings of a cool nature, such as that from old cowdung, and nodules of old cowdung that has been well dried may form part of the compost. A little manure, if carefully applied, does the plants no harm, except the very tenderness of those fixed to blocks, and even these we have seen dipped in weak solutions of manure with advantage. The words "at least 3 feet high," at page 598 of the *Cottage Gardener's Dictionary* should be struck out.

FOUR BEDDING-OUT GERANIUMS (W. C. H. N. D.).—If we were confined to four kinds, we would have Christine (pink-flowered), Tom Thumb or Crystal Palace (scarlet), Bijou as a white-edged, and either Cloth of Gold or Golden Circle as a yellow-edged one. Two more kinds would do for the largest garden—that is, Mangles' Variegated or Shottesham Pet, and a deep rose-coloured one as Rubrum or Paul d'Abbe.

PINK VERBENA AND EDINGE FOR VERBENA (Idem).—As a rosy pink, Great Eastern is very good, while Ida is a delicate pink. Some of the shaded or fancy sorts make a very good pink, by the blending of the two colours composing each flower. One of the best that way is Herman Steiger, an old kind. Amongst new ones, Cheerful is a good pink; but there are so many tints having the name pink that it is difficult for one person to choose for another. As an edging for a bed on grass, the old Variegated Alyssum keeps pace with the growth of the Verbena best; and excepting for a light-coloured variety, it looks as well as anything; but if the flower be white try Perilla, or Lobelia speciosa.

FRAME HEATED BY A FLUE (J. E.).—It is most likely there has been an escape of smoke from your flue, but the same evil would arise from too much heat; by neglecting to give air sufficiently early on a bright sunny day, the small volume of air in a frame quickly becomes overheated, and bad results follow. If, however, your Cucumber plants be likely to recover, it is certainly not advisable to disturb the flue and all the contents of the frame if it can be avoided. First, therefore, ascertain, if you can, where the escape of smoke is, and if there be a drain-pipe at that place stop it up. We presume your drain-pipes are placed upon the flue and not exactly communicating with the chamber. If the latter, however, be the case, the temporary remedy is more difficult; but as the season is fast advancing when atmospheric heat will be less wanted, you might partly stop the pipes up with moss that had previously been scalded, to kill all insect life in it. A little moss put in each pipe and frequently wetted will filter the heat of some of its impurities and charge it with moisture suitable to the wants of the plants inside, Cucumbers especially delighting in a nice, agreeable, humid atmosphere. It is generally easy to detect any pernicious vapours in a pit or house by inhaling the air after previously being some time in the open air. Most gardeners know by the test of their lungs when the heat is a nice and sweet one, free alike from the rankness of unprepared dung or the smell of an Ayrton stove which fire-heated surfaces often give off. If, however, your flue be too bad to go on for the present crop, by all means have it rectified, and we have no doubt but it will act. At the same time try and bring the first light into use if you are restricted for space laterally for your fireplace. Then go deeper, so as to have the extra room above for the hot-air chamber and other overheating precautions. If your frame be a close-fitting one, it would be better to have a small opening at the back at all times. Many impurities would pass off that way that might be hurtful to the plants inside; and as you reside where coals are cheap, the little extra expense in fuel is of little moment.

NAMES OF APPLES (W. Hilder).—1, Russet Nonpareil; 2, Colonel Vaughan's; 3, Not known; 4, Court of Wick; 5, Not known.

NAMES OF PLANTS (W. C. C.).—A smooth-leaved Laureline, probably a weak shoot of the var. lucida; Erica carnea. (John Gray).—1, Notholaena distans; 2, Asplenium trichomanes; 3, Blechnum spicant; 4 and 6, Lastrea Sieboldii; 5, Woodwardia (Doodia) caudata.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE POULTRY CLUB.

UNDER the authority of this newly-formed Society a circular has just been issued. It embraces not only the proposed future operations of the collected body of its members, but also explicitly points out the evil it is intended to eradicate. In the first place it proceeds to avow the formation of the Society has arisen from "the very different awards of the judges, and the diametrically opposite opinions of arbitrators on certain points, as exemplified at our different public poultry exhibitions."

True it is that such variances of opinions have "led to the confusion" complained of; but the primary question is this: From what particular causes do these complaints arise? Decidedly the most important of our shows leave but little room for amendment in the matter of the arbitrations; but on the

contrary, not a few of our minor meetings have justly called forth considerable animadversions from the irregularity of the awards, and the perplexities thus caused to breeders.

A case in point occurring not long since is an apt illustration of the majority of instances of such misunderstandings. A show that had for many years past held its annual meetings with unvarying and increasing success, repeatedly added small sums to its surplus incomes, and promised a great increase both of size and popularity as time progressed. Unfortunately for the welfare of the Society, a new resident in the locality, himself a poultry-fancier, and then a subscriber of £5 to its revenues, proposed an alteration in respect to the previous arrangements for adjudications, which he assured the committee would prove most advantageous on the balance sheets, saving an outlay of about the amount of his subscription that had been hitherto expended in judges' fees, and an arrangement which he was convinced would also meet with universal approval when the awards were made known. The experiment was tried; as the gentleman, on whose behalf the application in committee was made, assured, that body by letter, that "he had been an enthusiastic breeder of almost every variety of poultry for more than twenty-five years, and that he had not the slightest fear as to his competency to fulfil the duties to the satisfaction of all." Again, he stated, "as it was his greatest ambition to become a poultry judge, he would not object to give two guineas to the Society, besides paying all his own expenses, if his offer were excepted." He came to duty, bearing with him not only a well-known publication for instant reference should difficulty arise, but also a manuscript of his own, written expressly for this occasion. The result was, that though the Show was advertised to open as heretofore at midday, the arbitrator now appointed had not quite completed his awards at 7 P.M. In a private letter one of the Committee since writes: "Our show is for ever ruined. The instances in which the awards were obvious enough to any poultry-lover, were got through efficiently and speedily; but in almost every case, in which competition arose, a delay of very considerable duration immediately ensued for the purpose of reference, and thus eventually the premiums then under consideration were given quite as frequently to the worst as to the better pens." The Judge declared his difficulty arose from the application of his rules to the birds before him. "In his hurry to 'skedaddle,' he left his books behind him, which (both the printed and manuscript) were unquestionably good. It would have paid our purpose better," says the Committeeman, "to have given Mr. — fifty or a hundred pounds to have stopped away."

The fact is, it wants the greatest practical experience in a poultry judge to select at once by the eye, and nicely to balance the proportionate excellence of rival pens in the short space of time allotted to the duty. It is a natural gift to a great extent; for which book-learning will never prove a fitting substitute.

It is certain, too, that our principal shows will never succumb to the dictations of the "Poultry Club," involving as it will most probably, contending personal interests; neither will the managing committee of our lesser exhibitions fail to hesitate before placing the well-doing of their particular meetings in the hands of comparative strangers. A local committee of any show must of necessity prove the most effective in its own management. Again, it is probable that none of our most reputed judges of poultry will accept office encompassed with leading-strings, or aid in furnishing the code of rules on which, by their printed admission, the successful hopes of this embryo Society depend. In our opinion, it is evident that the proposed Club is an abortion without life or power, and although formed to suppress all causes for future grumblings, yet itself it would become, if allowed to act, the nursery of dissatisfaction.

Lastly, the assumption of power by such stewards, "as happen to be present" at any local meeting where the rules of the Club are in force, will subject themselves to no very pleasing amount of personal reflections by the attempt, when called upon, as provided "to deal with the case as they think proper," in cases, too, where even they may themselves be interested competitors. Without vastly improved rules and regulations to those now issued, failure is inevitable.

REAL SPRING CHICKENS.

SAYS Mary Powell, "The sojourn of the Court at Oxford, and the number of troops and officers on duty, do cause great demand for the spring chickens and ducklings in the yard."

Spring chickens did not always bear that name. They were once called—they are now in some places—"Asparagus chickens:" the two came together. They were called, also, "Paper chickens:" little white fat things used to come in small baskets, and each was carefully wrapped in soft paper. In France they are called the *poulets à la Reine*.

"What's in a name?" Asparagus, paper, spring, or *à la Reine*—few things are so delicious. People have no idea of the extent of the trade carried on by a small portion of Sussex, nor of the amount of money turned. At this time of the year the little delicacies make from 4s. to 5s. each. They seem to be among fowls like dwarfs among human beings—age brings no increase of size. The old form gets dry and wrinkled, but it is no larger.

It sometimes happens, at the end of a season, that the hen is killed with her progeny, and they all come up together. An unpractised eye would see little difference. They cannot be produced or made anywhere but in some parts of Sussex; and although they are the most perfect specimens of choice poultry that can be conceived, they have no outward indications of purity of breed, nor have they any distinctive marks or points. They are hatched perfect in shape, and in their onward progress they never arrive at an awkward age; nor are they ever all legs and wings, or ostrich-like, as many chickens are. Their merits as table poultry are of the first order; they are small-boned, very compact, full of meat. A paper-knife would carve one well. A joint left on a plate for a time will be found, when cold, to be bedded in its own jelly. He who has not tasted one of these, carefully boiled, and eaten with a little lemon juice and salt, has yet something to try.

We are speaking of the perfect. We shall appear paradoxical when we say no young fowl will make one of these chickens: one of these chickens will never make a fowl. Many thousands of pounds are returned for these every year from Leadenhall Market; and Sussex families have lived for many years, from father to son, by breeding and fattening these chickens.

HOW THEY OBTAIN CHICKENS GRATIS IN AMERICA.

ONE of our peculiar, slab-sided, gaunt Yankees lately emigrated and settled down in the West. He was the very picture of a mean man, but as he put himself to work in good earnest to get his house to rights, the neighbours willingly lent him a hand. After he had everything fixed to his notion, a thought struck him that he had no chickens, and he was powerfully fond of sucking raw eggs. He was too honest to steal them, and too mean to buy them. At last a thought struck him—he could borrow. He went to a neighbour and thus accosted him:—

"Wal, I reckon you hain't got an old hen nor nothin' you'd lend me for a few weeks, have you, neighbour?"

"I will lend you one with pleasure," replied the gentleman, picking out the very finest in the coop, one that happened to desire to sit.

The Yankee took the hen home, and then went to another neighbour and borrowed a dozen eggs. He then sat the hen, and in due course of time she hatched out a dozen chickens.

The Yankee was again puzzled; he could return the hen, but how was he to return the eggs? Another idea—and who ever saw a live Yankee without one?—he would keep the hen until she had laid a dozen eggs.

This he did, and then returned the hen and eggs to their respective owners, remarking as he did so:—

"Wal, I reckon I've got as fine a dozen of chickens as ever you laid your eyes on, and they didn't cost me a cent nuther."—(*Prairie Farmer*.)

SAFE ARRIVAL OF LIGURIAN BEES IN AUSTRALIA.

It will be perceived by the following paragraph, copied from the "Yeoman" of December 20th, that the four stocks of Ligurian bees, whose departure for the antipodes by the "Alhambra," on the 26th September last, was duly announced in THE JOURNAL OF HORTICULTURE of the 30th of that month, have reached their destination in safety. We certainly entertained hopes that one or two out of the four stocks would survive the voyage; but that not one should have failed surpasses our most sanguine expectations, and speaks volumes for the skill displayed by "A DEVONSHIRE BEE-KEEPER" in providing for the wants of the little travellers during their voyage. The result cannot

fail to be highly gratifying to him, as well as to Mr. Edward Wilson, to whose public spirit, we believe, the colony is indebted for this interesting importation, and to Messrs. Neighbour and Son, through whom the order was given, and who superintended the transmission of the hives from Exeter to Southampton, their place of embarkation.

At a meeting of the Acclimatisation Society at Melbourne, a report was laid upon the table from the Apiarian Society, upon the state of the four hives of Ligurian bees lately arrived. It was to the effect, that, although a very large proportion of the bees had perished from the confinement, yet, in consequence of all the four queens being alive, the Society confidently anticipate that these will form the nucleus of an important addition to the bee-stock of the colony. The report stated that, in consequence of the small number of Ligurians left in each hive, it had been found necessary to strengthen the hives by placing with them some of the common bees to provide the necessary food, and also for the sake of warmth; but this proceeding will in no way impair the ultimate purity of the new swarms of bees issuing from these hives.

BEE-KEEPING AT BATH.

In the frontispiece of Jardine's Natural History, vol. vi., "Bees," 1840, is a very pretty drawing of a honey bee on a heathbell. The moral and the execution were so good, that I had it cut on my signet ring, and it has afforded me many a lesson. It was as a word in season. Since then I have wished to become a bee-keeper, but never carried my desire into effect till the spring of 1862, when, stimulated by the discussions as to the respective merits of the common and of the Ligurian bees, I purchased the "Bee-Keeper's Manual," by Henry Taylor. Thinking it desirable to obtain some experience in management before incurring the expense of £5 5s. for a swarm of Ligurians in Mr. Woodbury's hive, I had a bar-hive made in accordance with Taylor's directions, page 56. To be able to compare this with the Woodbury bar-hive, Messrs. Neighbour supplied me with one ready for use. My limited experience has shown me the advantage of this latter shape. The interval between the bars and the top-board permits the bees free access to all parts of the hive, and to ascend by several ways to the super. Moreover, the shape of the Woodbury-bars does not allow the bees so readily to form their combs in any but parallel lines. I have found that though a point of the combs in the flat-bar hive may be attached square with the side, other combs are built in different directions, just as the fancy of the first formation arose: consequently it would not be possible to remove any one bar without destroying much comb. On the other hand, the shape of the Woodbury-bar is so defined, that though the comb may not be made in a strictly straight line, a bar might be removed without much disturbance of the neighbouring comb. There can, however, be no doubt that the bees do not like to form a perfectly straight comb, however accurately a piece of guide-comb has been fixed on one or more bars.

My hive being ready, and the house for two hives ordered, late in the evening of April 26th a large swarm, called hereafter No. 1, was safely housed, unfortunately, in the novelty of the scene and operation, in the super (of Taylor's) hive. On May 3rd, another, No. 2, was properly hived in the Woodbury-hive. My garden being quite a third of a mile away, my pets cannot be watched, especially by one who from many occupations cannot see them after breakfast; nevertheless, as they have the range of very extensive public gardens, abounding in all the growing trees and shrubs that are known to be fit for this climate, besides suburban gardens well stocked with apple, pear, and other fruit trees, as well as miles of pasture land, they thrive very well, and return laden with pollen, which, from the abundant bloom of the red chestnut and red hawthorn, is more often red than yellow or white, as is usually the case.

After a while, hive No. 2 became filled with comb, and the bees began to cluster on the alighting-board, when the super was added. This was quite filled with comb in the course of the summer. No. 1 never did so well—no clustering, no need to add the super. In the autumn I removed the super and found a small quantity of liquid honey, which never solidified. I gave each hive barley-sugar. The same difference of vigour characterised my two hives. No. 1 would take none, while No. 2 fed freely. In the middle of November the troughs were taken away, the closing-blocks put in their places.

The last week of January I removed the hives from their boards, which I scraped and cleaned, as the crocus was showing bloom, and I thought they might be stirring out to see the world once more. All were then alive, but No. 1 was very light. I had ordered barleysugar to be in readiness, but, unfortunately, the cook had made it of brown sugar, and it was toffee, not barley-sugar, and I feared to give them this. This delay appeared to have been fatal, for within a week I noticed after a very fine day a large number of bees were dead in front of No. 1, and within it there was not one alive. It was a case of starvation, not a particle of anything edible was there to be found. Numbers had buried themselves in the cells in the faint attempt to find sustenance. The queen seemed to be perfect. The barleysugar came too late. The lesson I have thus early learnt is to feed my bees.

In the month of August, outside the hives I found many of the enclosed, which I presume to be larvae of the drones, as about this time the drones became less numerous, and far more languid in their movements; shortly afterwards they wholly disappeared. My bees are at present (March 4th) enjoying their feeding-trough, but do not eat so much as I had expected. When should the trough be removed? I judge from a letter in a recent Number, that the air which must necessarily pass through the hive to it tends to keep the hive cool, and so to delay the formation of brood. On lifting No. 2 I found several small white maggots beneath the edge of the box. Were these the maggots of the wax moth mentioned as one of the enemies of the hive?

Can I venture to give my bees the brown sugar cake, or must it be thrown away? I have a friend who for more than twenty years has had a Nutt's hive with the side boxes fixed in his wall with the door behind. These have thriven according to the season; but his gardener is so afraid of them, that except to move the zinc slips to give admittance to the sides, they are never touched or interfered with in any way, still they thrive; and they gave a large quantity of first-rate honey in 1861—a good illustration of the wise maxim to let well alone.—B. J. S.

[It is very possible that what you enclosed were drone larvae, but they had disappeared before your letter reached us. If closely covered, the feeding-trough will do little harm, although we decidedly prefer the bottle. We have given bees brown sugar in the form you describe, without any evil results, and, therefore, see no reason why you should not use up what you have on hand, although it might not be advisable to give it habitually. The white maggots found under the edge of the box were, doubtless, the larvae of the wax moth.]

FERTILE QUEENS—DISTANCE BEES FLY— HONEY SEASON.

The remarks of "A LANARKSHIRE BEE-KEEPER," in your excellent Journal of March 3rd, powerfully revive in my mind the two questions I ventured to put a few weeks ago. The first was, What is the best method of insuring a succession of fertile queens? The second, Are there any facts determining the distance of the flight of the bees in search of honey? I sincerely hope some of your correspondents will afford us a reply.

The remarks to which I particularly refer are these: "They might do very well in good honey weather; but as the honey season generally lasts only about two weeks here, they would, probably, lose a great many bees in ordinary weather." The fact stated in these words I think not sufficiently appreciated. "The honey season" I believe to be short everywhere; but will our friend kindly inform us which he considers to be about these two important weeks, and also what flowers bloom then from which the bees gather their harvest? How much must depend upon their proximity to the apiary? Probably the "season" may occur at different times in different localities, as the same flowers may not be within reach of the bees in different places.

I have often been surprised at the apparent contradiction even of my own observations, in their increase or decrease of weight at different periods, and my observations again differed from those of others; but as there never was an effect without a cause, one feels earnest in the desire to comprehend some of those causes which produce the mysteries as witnessed amongst "our favourites."

I know that the keen observing eyes of those I could name

among your correspondents, may see perfectly what appears so strange to us. If, therefore, they will favour us with the benefit of their knowledge we shall esteem ourselves happy.—EDWD. FAIRBROTHER, Woolwich.

P.S.—I might subscribe myself "A LONDON BEE-KEEPER," and not be far out.

[We shall be very glad if any of our able correspondents will reply to the questions asked by Mr. Fairbrother. We ourselves find it difficult to do so with any great degree of certainty. "Destroy first swarms and keep old stocks," is a very good maxim for the old-fashioned bee-keeper who wishes to secure young queens, but beyond this little can be said, unless we advise our correspondent to become a first-rate operator like "A DEVONSHIRE BEE-KEEPER" and others, in which case he will find the selection and renewal of queens easy enough. The time of honey harvest varies in different localities, and in different years. In some, such as 1860 and 1862, it never occurs at all. We know of no facts positively determining the distance traversed by bees in search of honey. Huish is so notoriously unreliable, that we do not think much of his authority. Without, therefore, any very decisive information to guide us, we venture an opinion with some diffidence, although it is founded on an experience of many years. We believe that the range to which the honey bee can profitably extend its flight is limited to a radius of a mile, or at the outside a mile and a half.]

BEE-KEEPING IN THE NORTH OF SCOTLAND.

AN old and formerly a very successful apiarian writes as follows:—"Absence from home and a careless gardener have reduced my once-numerous colonies to one stock; and another wet summer will certainly finish-off the very few remaining bees in the north. We depended chiefly on heather for main crops of honey, and I can only describe our weather for the last three years, by saying that my stocks sent to the heather about the 20th of July, that used to come back well filled, have uniformly returned lighter than they went; the incessant rain completely preventing all collecting of honey, and obliging my poor friends to use up the little they had made in summer. Formerly less rain used to fall in summer hereabouts than in any other part of Britain, and we had frost and snow in winter, which now are a matter of surprise."—M.

OUR LETTER BOX.

HENS WITH SWOLLEN EYES (*J. A. Bolton*).—Your fowls have incipient roup among them. Separate sickly from healthy birds. Give them castor oil and Bailey's pills. Feed on bread and ale, and let them have green meat. Wash their faces with cold water, vinegar, and camphor julep. It only adds to the suffering to tie up the legs and prevent a comfortable scratch.

MALAY FOWLS (*Rustic Robin*).—"Pheasant Malays" and "Malays" are as distinct as Hottentots and Caucasians. The Pheasant Malay is, properly speaking, an Indian Game fowl. It is essentially a bird of feather, quite distinct in every particular from the bird we described. Yours should be covered with feathers of a rich deep chocolate, spotted all over with spots of a glossy green black. They should have bright yellow legs, and be neither as high nor as large as the Malay.

CRÈVE CŒUR FOWLS NOT LAYING (*Lady Amateur*).—There are two things wrong in the treatment of your fowls. Either would account for partial failure, and together they may account for all your disappointment. The paved yard is very bad, and it mends it little to cover it with straw. Cover with loose gravel, mould, road sand and bricklayers' rubbish, or what you will, a few inches deep; it will keep sweet and afford a scratch, but straw will not. Next, you overfeed, and your fowls are too fat to lay. Give ground oats slaked with water night and morning. Feed on what you will at midday. Your expenses will be less, and your eggs tenfold.

LIGURIAN BEES (*B. G. S.*).—T. Woodbury, Esq., Mount Radford, Exeter, can supply you.

WORK ON BEES (*R. Legett*).—Mr. Payne's "Bee-keeping for the Many" can be had post free from our office if you enclose five postage stamps. Mr. Payne's hive is the most simple and effectual for managing bees cheaply on the depriving system. We know a party who supplies a hive and its super complete, money paid in advance.

CHOICE OF HIVES—LIGURIAN BEES (*C. E.*).—We are not acquainted with Knight's hives, nor, in fact, are we disposed to recommend any particular description of bee-hive. Why not pay a visit to Messrs. Neighbour and Sons, at 149, Regent Street, where you will find a large assortment of all kinds, from Payne's Improved cottage-hive at half-a-crown up to any price you please. For information respecting the Italians, write to T. Woodbury, Esq., Mount Radford, Exeter.

BERKSHIRE PIGS WANTED (*J. G.*).—You had better advertise in our columns, and you will have replies with more particulars than we can give you.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 55.7° and 38.3° respectively. The greatest heat, 78°, occurred on the 3rd, in 1848; and the lowest cold, 16°, on the 1st, in 1838. During the period 143 days were fine, and on 109 rain fell.

FERTILISATION OF ORCHIDS.

AD Mr. Anderson asked me two days ago for any facts illustrative of his case of unopened flowers of *Cattleya crispa* and *Dendrobium cretaceum* producing seed-capsules, I could have given no sort of information; nor can I now explain the fact. By an odd coincidence, yesterday I received a very interesting letter from Dr. Hermann Cruger, the Director of the Botanic Garden at Trinidad, who informs me that certain native species, and native species alone, of *Cattleya*, *Epidendrum*, and *Schomburgkia*, “are hardly ever known to open their flowers, but which nearly always set fruit.”

In answer to Dr. Cruger, I have asked him to look at the seed or send me some, and inform me whether it appears good.

Will Mr. Anderson have the kindness to send me a few seeds produced by his unopened flowers?

I further asked Dr. Cruger whether these Orchids in their native haunts *never* open their flowers. I can hardly believe that this can be the case, seeing how manifestly adapted the structure of their organs of fructification is to the action of insects. But it is known that several plants, such as Violets, Campanulas, Oxalis, &c., produce two kinds of flowers: one sort adapted for self-fertilisation, and the other sort for fertilisation by insect agency or other means. In some cases the two kinds of flowers differ very little in structure; and it occurs to me as possible that something of this kind may occur with Orchids.

Dr. Cruger further informs me that with certain Orchids, as in those which do not open their flowers, the pollen-masses after a time become pulpy; and though remaining still *in situ*, emit their pollen-tubes, which reach the stigma, and thus cause fertilisation.

An excellent observer, Mr. J. Scott, of the Royal Botanic Gardens of Edinburgh, will, I am sure, permit me to state that he has been making similar observations, and has seen the pollen-tubes emitted from the pollen-masses whilst still in their proper positions.

These facts were all unknown to me when I published my small work on the Fertilisation of Orchids; but I ought, perhaps, to have anticipated their occurrence, for I saw the pollen-tubes emitted from the pollen within the anthers in the Bird's-nest Orchid, and likewise in monstrous flowers of the Man Orchis. This latter fact seems related to Mr. Anderson's remark, that flowers of an imperfect character, wanting a petal or sepal, had a great tendency to produce seed-capsules.

These curious observations by Dr. Cruger, Mr. Anderson, and Mr. Scott, convince me that I have in my

No. 105.—VOL. IV., NEW SERIES.

work underrated the power of tropical Orchids occasionally to produce seed without the aid of insects; but I am not shaken in my belief that their structure is mainly related to insect agency. With most British Orchids this conclusion may be looked on as established.

I will only add that since the publication of my work, a number of persons have set seed-capsules with various tropical Orchids.

CHARLES DARWIN, *Down, Bromley, Kent.*

HISTORY AND CULTURE OF THE CHRYSANTHEMUM.

MR. GLENNY wrote, about eighteen months since, a very interesting article on the introduction of the Chinese Chrysanthemum into England. He says it flowered for the first time in this country at Mr. Colville's Nursery, King's Road, Chelsea, in November, 1795, in which year the name Chrysanthemum (Golden Flower), was first given to it by Linnaeus, who distinguished two species, calling the one with a small flower, *indicum*; and the other with a large flower, *sinense*. But after his time a diversity of opinions arose among botanists as to the proper name, some of them saying the plant belonged to the *Anthemis grandiflora*, *Anthemis artemisiæfolia*, and *Anthemis stipulacea* (Camomiles). Modern English writers call it Chrysanthemum, with the exception of Sweet, who considers it a species of *Pyrethrum*, or *Feverfew*, and places it under the head of *Dendratheuma* (shrubby kinds). These differences of opinion arise from the small membranous scales resembling chaff found on the receptacle of the flowers of the Chinese Chrysanthemum at the base of the florets, such being characteristic of the genus *Anthemis*, while the receptacle of the true genus Chrysanthemum is without chaff-like scales. Nevertheless, they are in my opinion both the same genus.

In the “Horticultural Society's Transactions” of 1831, a history of the Chrysanthemum is given by Mr. Sabine, who says they were cultivated in the gardens of Holland, and described by the celebrated Breynius as far back as 1688. He calls it *Matricaria japonica*, and speaks of six varieties. They appear afterwards to have been lost, as no gardener in 1821 knew anything of them.

In January, 1826, Mr. Sabine, again referring to the Chrysanthemum, says, speaking of the rapid progress the flower had made in this country in a few years, that the shows of the flower at the Society's gardens in 1824 and 1825, had been acknowledged by its admirers to be, taking them as a mass, the most splendid and gorgeous exhibitions ever seen even in the gayest time of the year. The Show consisted of seven hundred pot plants. They began to bloom in October, and continued till December, with now and then changing a few of them for later-blooming ones, thus enlivening the garden at a period when there was nothing else to attract attention. Many of these varieties were collected by Mr. Parks in China and Bengal during 1821, and some of them were sent home by the Society's gardener, Mr. John Potts.

No. 757.—VOL. XXIX., OLD SERIES.

The whole of the varieties in the garden at this period were forty-eight. These were introduced into the gardens of England at the following times—one came from China to France in 1789, and was brought to Kew from Paris in 1790; seven from Sir Abraham Hume, between 1798 and 1808; one from Mr. Evans, in 1802; one by Capt. Rawes, in 1816; one by Capt. Larkins, in 1817; one by Messrs. Brookes, in 1819; one by Mr. Reeves, in 1824; two from whom not known; four are English sports; and the remainder were sent from China by the Society's agents up to 1824. Mr. Colville, a nurseryman at Chelsea, sent to the Society a sport in 1822, of a pale Pink, grown from the Changeable Buff; coloured plates of several varieties of which were shown—viz., the Early Blush, Parke's Small Yellow, Blush Ranunculus, the Tasselled Yellow, the Changeable Buff, the Curled Blush, the Tasselled Lilac, and Two-coloured Red, the Pale Buff, the Windsor Small Yellow, the Clustered Yellow, the Clustered Pink, the Semi-double Orange, the Starry Purple, the Golden Lotus, the Brown Purple, the Two-coloured Incurved, the Late Quilled Yellow, Waratah, the Yellow Indian, the Double White Indian, the Small Yellow, the Quilled Pink, the Semi-double Pink, the Semi-double Quilled Orange, and the Pale Purple.

Mr. Munro, in a paper read before the Horticultural Society, in January, 1826, says—"Since the establishment of the Society in the year 1818, considerable attention has been paid to the culture of this plant, and the improvement is so great in its appearance that it rivals those grown in its native country." He then gives his mode of treatment, and I find his directions differ in a very trifling degree from what is generally practised now, both as regards compost and supplying liquid manures; and I have no doubt that in those days, had he possessed our present improved varieties, he would have grown them as fine. He speaks of a Mr. Joseph Wells as the best grower of that day, and recommends thinning the buds and watering with liquid manure as practised at the present day. On account of their delicacy, the idea of growing them in open borders was abandoned, except against south walls, while we have improved varieties sufficiently acclimatised to flower freely in the open borders.

The best mode of managing Chrysanthemums in the border I have found to be the following:—Remove the plants after cutting them down, and put them in close together in a sheltered part of the garden, covering them with a framework of thin laths to guard them from frost. When sufficiently grown—say 4 inches long, take off the suckers, and put them in small pots in light, sandy loam, on a south border, in rows, protecting them from the frost, and giving just enough water to keep them growing. If you can put them in cold frames so much the better. Then dig up the border 2 feet deep, mixing a little rotten dung with a good dressing of fibrous, turfy loam, and fork-in 8 or 9 inches deep. Let it lie rough for the winter to sweeten; plant out in the end of March, if the weather is favourable, giving to each plant a good handful of cocoa-nut fibre, which keeps the worms from it till it is well rooted. Plant the strongest suckers 2 feet apart, taking care the sparrows do not peck out the crown. Take off all side laterals as they throw out, till they show the second flower-bud. In July retain the three shoots thrown out from the crown, and take off all side shoots from the three branches as before till the flower-bud shows itself. Mulch the borders in August with cocoa-nut fibre, leaf mould, or rotten dung. Water with weak liquid manure from the 1st of August till they show their colours, and do not allow the plants to starve for want of plain water, as this throws them back, and when recovering they are apt to make a second growth, which prevents them blooming so early.

Cover them over the first week in October, to guard against frost, and if you have a frame and can put on glass they will bloom much finer and cleaner than with canvas. All buds not showing colour in October are of little use, as they seldom come to maturity in November, and it is generally so cold that the work must all be done in September and October, for border-blooming. If against south walls they will bloom much finer, as they are not so liable to the draughts as under canvas. If grown in eight-inch pots they must be treated in the same manner as in borders, except that they require a stronger liquid manure with good drainage; and if the water do not pass freely through, force through the mould a thin wire all over the pot, to open a drainage.

Now for a few words regarding the Pompon, or Chrysanthemum indicum flore pleno. About the year 1845, Mr. Fortune brought to the Society's gardens from Chusan a small semi-double, reddish, or light brown Chrysanthemum, which he called

the Chusan Daisy, on account of finding it at Chusan. The Society propagated it, and distributed it among its members. Thence it was carried to France, and came into the hands of M. Lebois, of Paris, an ardent lover of the Chrysanthemum. He seeded it, the climate being better adapted for ripening the seed than that of this country. From the seed thus obtained he raised a great many beautiful varieties of various colours, some of them exquisitely formed, and perfectly symmetrical, and, consequently, the majority of our present collections came from this source, having been obtained by Mr. Salter, of Hammer-smith. Still, I find coloured plates of beautiful Pompons in the Society's "Transactions," as far back as February, 1821.

The French gave it the name of Pompon, on account of its small compact bloom, resembling the tuft or pompon on a soldier's cap.

The following is the method adopted by me in the culture of large varieties in five-inch pots, from cuttings in June:—Last year I purchased all Mr. Salter's and Mr. Bird's new varieties. They were delivered to me in May, and I planted them out in the borders on receiving them, and allowed them to become naturalised to the smoky atmosphere for three weeks, which brought them up to the first week in June. I then took the tops off 3 inches long, and put the cuttings into 60-sized pots, one in each pot, draining the pot with a little cocoa-nut fibre, and filling up with mould composed of half light loam and half silver sand. I then plunged the pots in the front of a cucumber-frame, of the temperature of new milk, and shaded for a fortnight, giving a little watering occasionally. By the 1st of July they were well rooted. I then repotted them into five-inch pots drained with cocoa-nut fibre, the compost being two-thirds fibrous maiden loam from Epping Forest, one-third rotten dung, and one-third decayed leaf mould, pressing the mould firmly round the sides of the pot. I then put them in a cold frame for nine days with a little air to harden them off, and afterwards removed them to a sheltered, sunny spot for three weeks, attending to the watering, and every evening syringing the foliage to wash off the fallen soot, and keep off insects:

At the end of three weeks I plunged them three parts down in the front of the border, making the hole much deeper than the pot in order to obtain a free drainage. I then commenced giving weak liquid manure, composed of horse, sheep, and cow dung, all mixed together in a tub, and this I continued to follow up till they showed the colour of the flower. As soon as they began to show and throw out their side shoots I picked these out, and continued to do so till they showed their flower-bud, which was in the end of August. When the bud was properly formed I took off the side shoots on each side of the bud, where the bud looked healthy and promising; but I was obliged to let several go on to the second shoot. These did not bloom quite so early, but all did very well. The average height was 18 inches, with healthy foliage to the rim of the pot, and the blooms as perfect and nearly as large as those plants in the borders with unlimited space for growth. They bloomed in the first week in November, and attracted more notice than all the other flowers on account of the short foliage.

This system of growing large, well-shaped blooms in small pots would give very attractive specimens for exhibitions, and they might afterwards be brought into use for decorating greenhouses or cottage windows, and be kept in bloom for a month, and it is far preferable to cutting the bloom off to show, and afterwards perish in a day or two. Some of the best varieties to grow for this purpose are, of the larger kinds—Antonelli, Cardinal Wiseman, Her Majesty, Lord Palmerston, Princess Alexandra, Talbot, Cherub, Dido, Duchess of Wellington, Dupont de l'Eure, Emily, General Harding, General Slade, Globe, Ion, Jardin des Plantes, Julia Grisi, Lady Harding, Little Harry, Lord of the Isles, Madam Lebois, Marshal Duroc, Nil Desperandum, Novelty, Plutus, Raymond, Rifeman, Sparkler, Vesta, and Yellow Perfection. Of the small kinds, or Pompons—Fairest of the Fair, Julia Engelbach, Lilac Cedo Nulli, Cedo Nulli, Golden Cedo Nulli, Andromeda, Bob, Christiana, Hélène, Graziella, Jessie, Miss Julia, Mustapha, Sainte Thais, and Pyramidalis.

If the grower prefers a quantity of blooms instead of very large single ones, the flower-bud should be taken off, and the stopped side shoots allowed to remain. These will produce seven or eight blooms, but they will not flower as soon as the single bloom.

SEEDING THE CHRYSANTHEMUM.

The following mode I saw practised in Guernsey, where I went

four years ago, at Christmas, to look after some new varieties. At the town of St. Peter's, which is built on a rock a considerable height above the sea, I found the Chrysanthemum seeded freely, and that many of our newest and best varieties were raised in an alcove on the top of a rock. About one hundred pots were crowded together in the dry, and all the late blooms of the season were full of seed half ripe. I saw the petals had been carefully cut off with a sharp pair of scissors close to the florets, avoiding disturbing the pollen. The buds were quite firm with the seed. I have practised the same mode myself with perfect success. Mr. Wyness, of Buckingham Palace, has also raised a great number of very good varieties. He takes the seed off in February, and puts it into his pocket to dry for a week or two, and then sows it in a sharp heat in silver sand, and it comes up in nine days. I am persuaded that any one can seed them in the greenhouses or dry stoves in this country if kept free from damp.

INSECT ENEMIES.

The Chrysanthemum, like the Rose, Holly, Celery, and some other plants, is injured by having its leaves mined by caterpillars, which reside within the leaf and feed upon the parenchyma or pulpy part of the leaf; for if the injured leaves are examined the interior will be found quite destitute of pulp, and to contain one or several small green grubs of different sizes, which have eaten all the interior, leaving only the two surfaces of the leaf entire, and those very thin. The grub when feeding may be observed through the transparent surface of the leaf, using the two bent hooks or mandibles which it has the power to retract within or protrude from the mouth like a pair of scrapers, and by the action of which the parenchyma is entirely destroyed, and brought into a state to pass into the mouth of the larva without difficulty. When the grubs are full grown they quit the leaves and descend into the earth, where they shortly afterwards gradually become pupæ, and appear to lose all vitality, their form becoming shorter and oval, with the segments distinct and terminated at each end by two obtuse points. In this state the insect remains buried in the ground until the following spring, when the warmth gives birth to the imago of one of the most beautiful of our species of two-winged flies, which after throwing off its pupa skin and bursting through the hardened pellicle of the larva, crawls to the surface of the ground and takes flight, generally during the months of July and August; but more or less throughout the summer. There is no doubt but like the house fly, a succession of generations is produced throughout the season.

The insect of which the caterpillar mines Chrysanthemum leaves, belongs to the Dipterous or Two-winged genus, *Tephritis* of Fabricius, and is the *Tephritis artemisiæ* of Curtis, and the *Tryptera artemisiæ* of Walker, in the "Entomological Magazine," No. XI., page 84. The fly itself is about one-sixth of an inch long, and the expansion of the wings when fully extended is about one-third of an inch. It is of a pale yellowish-buff colour with a few black hairs, especially at the sides of the thorax (breast). The wings are limpid and slightly tinged with a yellowish colour, having several black spots of various shapes and sizes, and three uninterrupted bands across the body vary, in different specimens, from a rusty brown to a shining black. The head is buff with black lateral hairs, and the wings are marked with various limpid spots of various forms and sizes. In some specimens the dark marking of the wings is varied with a pale copper colour, and these present a still more beautiful appearance, the under side of the body being of a paler yellow, with the abdomen and thorax highly polished.

To destroy this perfect fly seems impracticable: therefore, the extermination of the insect must be looked to from the earliest time of their appearance in the caterpillar state. Picking off the infested leaves, or the crushing of the larva between the finger and thumb without destroying the leaf, appears the best and only mode likely to prove successful, if adopted in the beginning of summer, as the destruction of one grub at that period will not only prevent the production of a numerous progeny, but will also insure the better growth of the yet tender plant. The motions of the fly are also very peculiar, for when seated upon a leaf in the sunshine the wings are carried partially extended and at the same time partially elevated, and there is a sidling kind of motion which is possessed in common with but few other two-winged insects. It is generally found in the perfect state basking on the broad leaves of the Laurel and similar-leaved plants, as well as on the Chrysanthemum.—J. BROOME.

[The foregoing is a lecture delivered by Mr. Broome, whose cultivation of the Chrysanthemum in the Temple Gardens is so well known.]

THE PANSY.

ITS PAST HISTORY AND FUTURE PROSPECTS.

It may seem strange that I should occupy myself with a plant so common and old-fashioned, but like many things in other departments as well as in that of flowers, "it was in high repute once." Its day has not entirely gone yet; for some elderly gentlemen, occupying gardens in happy rural retreats, may still be found patronising a flower whose name harmonises so well with the abodes which it assists in adorning by its beauties. Neither has the fashionable florist entirely discarded it, and the list of prizes at country horticultural shows often contains one or more for Pansies. The pages of *THE JOURNAL OF HORTICULTURE* have from time to time been the means of placing its merits before the world as a bedding plant, and other modes of dealing with it have also been occasionally set forth; but as the articles on the subject have probably been lost sight of, a brief review of its merits, together with a slight sketch of its past history and present position, may not be unacceptable at a time when the great diversity of plants we possess renders it no easy matter to select the best.

It is impossible to say at what precise period the parent of our garden varieties of Heartsease, or Pansy, first attracted the attention of some zealous and far-seeing florist, who either spared it while destroying the other weeds in his garden, or transplanted it thither from the corn field or waste where he found it growing, for the plant (*Viola tricolor*), is a native one. At whatever date it was first introduced into gardens, the beginning of the present century found it an occupant of our mixed flower-borders, and in a state very considerably improved as compared with the parent; and its convenient mode of reproducing itself from seed, served the twofold purpose of originating new varieties and new plants to supply the place of the old ones, which seldom survived the hardships of half a dozen years.

The Pansy, however, was never honoured with much attention until about the year 1825, when its great adaptability to improvement, and the almost incalculable manner in which it could be propagated, as compared with the *Auricula*, *Ranunculus*, *Tulip*, &c., by which it had been preceded, led some enthusiastic person to bring it into notice; and so rapid was the improvement in its form and colours, that the botanist seemed almost at a loss whether to set down the fashionable occupants of a pan of Heartsease at a flower show as belonging to the genus *Viola* or not.

That all the improvements were effected at one time and by one individual it is scarcely necessary to say was not the case. A long category of names, including most of the celebrities of the day, lent able and skilful hands to the work. Amateurs and professionals alike entered into the spirit of the time, while censors settled the points by which the merits of each flower were to be judged. This work, of course, occupied some time; but I believe there was no previous example of a plant so quickly becoming fashionable, and at the same time so rapidly approaching perfection. The *Dahlia* was in the field some few years prior to it, but was several years in making much progress out of the single condition in which it first reached us. The Pansy, however, from being a second-class border flower, was quickly elevated into the condition of an occupant of the same beds that the *Tulip*, *Ranunculus*, &c., had held years before. Like them, the opening of fresh flowers was watched with interest. I believe the best varieties then in cultivation were first dignified with distinct names about 1829; and from 1832 to 1842 may be regarded as the most fashionable period of this flower.

The claims of other plants, and the changes in the public taste by the introduction of plants available for what we now call bedding purposes, were a heavy blow to florists' flowers; for although the Pansy continued to be well represented, and in many cases well patronised, its showy antagonists—the *Verbena*, *Petunia*, and other flowers, forced it from the position it once had; and though various attempts have been made to reinstate it by the introduction of varieties said to possess merits qualifying them for bedding purposes, it is only in some isolated places where these have been successful. It is, therefore, for other purposes than the ordinary summer decoration of the parterre that we must look for the Pansy again attracting attention.

Although, as we have stated, the Pansy has receded before the more fashionable occupants of the parterre of the present day in most places, there are localities where it still retains a respectable place, and these are where our variegated and other *Geraniums* do not succeed. The moist atmosphere of the north is more in accordance with the welfare of this plant than it is with that of many of its rivals, and in such situations beds of Pansies present a cheerful appearance. On the contrary, in dry sunny districts, with long periods in summer without any rain, this plant falls a victim to mildew, which it is not easy to arrest. Some years ago I had a tolerably good collection of show varieties of this plant, but one or two hot summers in succession reduced them sadly; so that eventually a yellow one called, I believe, Hon. Mrs. Harcourt, was the last survivor of a long array of names, aristocratic, warlike, and I fear I must say vulgar, for the caprice of those who give names to new plants or varieties descends to oddities as well as soars up to celebrities. Of this, however, it is not my purpose to speak; but continuing the history of the Pansy, I may say that at the present day the number of show varieties falls short of what it was twenty years ago; and I may also add, that the attempted introduction of very dark varieties into the bedding system did not receive much patronage, so that it has been left for another move in the history of the Pansy to again restore it to favour.

As before stated, the long dry summer in the south of England was sadly against the Pansy doing well, and in very many cases was fatal to it entirely. Though not an annual, its original state as an occupant in a corn field led to its destruction almost every year, and consequent reproduction by seed. This condition, however, was in some degree altered in the cultivated plant; still the tendency of the plant was to succumb when it had flowered and ripened seed, and when its roots felt the scorching effects of a bright sun in the dog days, for mildew carried off large numbers. It was, therefore, not without feelings of much satisfaction that some eight or ten years ago a new race of double Pansies was brought out, which certainly possess the qualification of withstanding the heats of summer better than any of the single sorts by which they were preceded. For many years I have disregarded all others but the double kinds, and have often turned them to useful account for furnishing the beds in winter, by striking cuttings in August, and planting them as soon as the beds were at liberty in autumn to receive them. Their tidy, stocky appearance improved the aspect of the beds; and, planted amongst Roses or in mixed borders of herbaceous plants, the double Pansy is always worth a place. The only drawback to the kind I have had so long is its liability to return to the single condition from which I expect it was originally a sport. Perhaps one or two plants in a bed may return to the condition, or parts of plants may do so; but in other respects the double is as perfect as could be wished, and the flowers bunch well in small bouquets.

I am glad, therefore, to see that other varieties in the double form are making their appearance, and hope they will be improvements on those we possess. I do not know the qualities of the one lately advertised in the columns of *THE JOURNAL OF HORTICULTURE*, but I should like it all the better if it were a clear bright yellow without the least tinge of other colour in it. Next to that, a good double white would be an acquisition. Perhaps I may be fastidious or whimsical in my choice; but I like best to look at a flower when in a growing state and attached to the plant, when, it is needless to say, its appearance differs widely from what it presents when forming along with others a bouquet, stand, or pan. In the latter case the artificial arrangement to which the flowers are subjected differs so widely from the contrast they individually would have to the plant that produced them, that a bed of flowers and a bouquet must ever be regarded as widely different. It is, therefore, to the clear yellow and clear white of the double Pansies that we must look for our flower-garden favourites in future; and however meritorious mixed coloured ones may be, there is no place for them in the bedding department.

It is hardly necessary here to advert to the easy manner in which the Pansy is propagated. Cuttings of the small wiry shoots from the centre of the plant are best, but the outside branches will also grow. All the preparation that is required is a little river sand spread over any border and slightly worked-in, a little more sand being placed on the top; then the cuttings may be put in and shaded for a week or two, watering of course when necessary. It is seldom that they are struck under glass. It is not unusual to put in cuttings of other hardy herbaceous

plants at the same time—as *Alyssum*, double *Rockets*, *Phlox*, *Pentstemons*, &c.; and if advantage can be taken of dull weather to do this work, the success will be the more certain.—J. ROBSON.

DISAS FROM THE CAPE.

AN answer is given to a question relative to these *Ochids* in the last Number, from which I beg respectfully to differ entirely, and by following it, I am inclined to think, "FRANK" would lose the best part of his collection. I do not know by name any of the *Disas* there mentioned except *grandiflora*, but they are probably allied species requiring the same treatment. That treatment I have more than once spoken of in *THE JOURNAL OF HORTICULTURE*; and shall, therefore, now merely say that it consists in treating the *Disa* in a totally different way to *Ochids* as generally so called. This beautiful terrestrial *Ochid* inhabits a ravine on the top of Table Mountain at the Cape of Good Hope; and as that is most frequently covered with the mists from the ocean, it will be at once seen that at so high an altitude, where the thermometer sinks to 32°, *Ochid*-house treatment would not suit it. I have seen quantities of *D. grandiflora* with my friend Mr. Leech, of Clapham Park, and have through his kindness a plant, now most vigorous, which will throw up its blooming-stem shortly; and this has been subjected simply to greenhouse treatment, with this addition—that it has stood in a pan of water ever since the autumn, and will continue to be so treated. I do not believe you can give it too much moisture; and I would advise "FRANK" to pot his into small pots in peat and sand, give them a good soaking, and, when the signs of growth manifest themselves, to keep them continually wet in a shady part of the greenhouse. Avoid the stove by all means. I should be glad to know by-and-by whether he has succeeded, and whether the sorts he names are all species, or whether some are not varieties of *D. grandiflora*. He may be confident that the only treatment that suits them is the one detailed above, for the knowledge of which we are indebted to Mr. Leech of Clapham.—D., Deal.

[We believe this treatment to be right; but we may hear on the subject from the authority who furnished us with the answer in our last.—EDS.]

THE ROYAL BOTANIC SOCIETY'S FIRST SPRING SHOW.

THE opening Show for the season was held on Saturday last, and for the early period of the year the display of flowering-plants was very good; whilst the beautiful cut *Roses* shown by Mr. W. Paul, of Waltham Cross, and Messrs. Paul, of Cheshunt, formed of themselves a most attractive feature. The objects exhibited were arranged with Mr. Marnock's usual good taste, on turf stages in one of the large tents, and the effect of the whole, especially when viewed from the end next the conservatory, was excellent.

Of *Hyacinths*, excellent collections were exhibited by Messrs. Cutbush, of Highgate, and Mr. W. Paul, who each furnished one hundred pots, the varieties being nearly if not exactly the same as those shown at Kensington on the 18th inst. Early *Tulips* were likewise shown in good perfection by both these gentlemen.

Of foliage and flowering plants, good collections were shown by Messrs. Veitch, A. Henderson & Co., Williams, and Bull.

Messrs. Veitch had a fine plant of *Rhododendron jasmiflorum*; Princess Bacciochi *Camellia*, a very handsome plant; *Maranta vittata*; *Eriostemon densifolium*; *Chamærops humilis*; and *Azalea Carminata*, a fine pyramid of crimson bloom.

Messrs. A. Henderson's plants consisted of *Eriostemon densifolium*, a nice bushy plant; *Boronia pinnata*; *Aphelexis macrantha purpurea*; a handsome plant of *Pandanus javanicus variegatus*; and large and fine specimens of *Dracæna ferrea* and *Maranta variegata*.

Mr. Bull contributed fine specimens of *Azalea Triumphant*, *Cibotium princeps*, *Gleichenia flabellata*, very large plants of *Pandanus utilis* and Chandler's *Elegans Camellia*, also *Yucca aloëfolia variegata*.

Mr. Williams, of Holloway, sent *Vanda suavis*, with a handsome spike of its beautiful flowers, *Pavetta borbonica*, *Cordylina indivisa*, *Azalea Empress Eugénie*, and fine plants of *Vanda insignis* and *Dendrobium nobile*.

Messrs. Lee, of Hammersmith, were likewise the exhibitors of a fine collection of plants, the same as that referred to in our columns of last week.

From Mr. Young, gardener to R. Barclay, Esq., of Highgate, came *Weigela rosea*, now well known as one of our best flowering shrubs both for in-door and out-door work, *Coleus Verschaffeltii*, handsomely grown and some 5 feet across, *Rhododendron Blandyanum*, *Caladium bicolor splendens*, *Azalea Fielderi*, and *Maranta zebrina*. Messrs. F. & A. Smith, of Dulwich, likewise showed collections of stove and greenhouse plants.

There was a class for Coniferous or other hardy evergreens in pots; and here Mr. Standish, of Ascot and Bagshot, stepped in with his new Japanese introductions, among which were the female plain-leaved *Aucuba*; *Retinospora pisifera aurea*, with its golden-tipped foliage; *Sciadopitys verticillata* and its yellow variegated variety; *Osmanthus ilicifolius* and its variety *aureus*; *Retinospora obtusa*; *Thujopsis dolabrata*, and the variety of the same with white variegations, and some others of the new acquisitions which we owe to Mr. Fortune's explorations.

Camellias were contributed by Messrs. Veitch, who had handsome plants of *Valtearedo*, *Alba plena*, *Alexina*, *Marie Morren*, a deep rose, and *Drysdali*; whilst the fine new varieties, *Queen of Beauties*, *Bicolor de la Reine*, and *Lavinia Maggi*, were exhibited by Mr. Standish.

Of Roses in pots, some magnificently flowered plants, which were the admiration of every one, came from Messrs. Paul and Son, of Cheshunt. They consisted of *Victor Verdier*, *Virginal*, *Madame Julie Daran*, *Jules Margottin*, *Goubault*, *Anna de Diesbach*, *Elize Sauvage*, *Madame de St. Joseph*, *Comtesse de Chabrillant*, *Solfaterre*, *Triomphe de l'Exposition*, *Louise Odier*, *Paul Ricaut* (the only one to which exception could be taken), and *l'Enfant Trouvé*, a beautiful yellow Tea.

To the cut Roses we have already alluded as affording a very attractive feature to the Show; but it would be tedious to enumerate all the varieties which were exhibited. It will suffice to say that nearly all the leading varieties were included in the collections, and that the flowers themselves were, with but few exceptions, all that could be desired.

Of other objects—Cyclamens were shown by Mr. Howard, gardener to B. Edgington, Esq., Wandsworth; Mr. Wiggins, gardener to W. Beck, Esq., Isleworth; and Mr. Holland, of Spring Grove, Hounslow; and the whole of the pots were very creditable to the exhibitors. Pansies came from Mr. Bragg, of Slough, and Mr. James, gardener to W. Watson, Esq. Chinese Primroses from Messrs. Cutbush and Mr. Todman. Cinerarias from Mr. Holland and Messrs. Dobson, of Isleworth, who, among others, had *Princess of Wales*, which seemed a promising sort, white, with a magenta edge.

Messrs. F. & A. Smith, of Dulwich, had several handsome double Chinese Primulas, seedling Cinerarias, their new double white *Azalea Flag of Truce*, and other plants, previously exhibited at Kensington.

In the class for new and rare plants Mr. Bull, of Chelsea, was a principal exhibitor. Many of the objects which were brought forward here have, however, been noticed in our previous reports, such as the *Yucca quadricolor* and *Stokesii*, *Pandanus elegantissimus*, *Nephelaphyllum cordatum*, &c. He had, besides, two bright scarlet *Amaryllises* called *Conqueror* and *Fire King*, which were very showy, and *Bougainvillea spectabilis* flowered in a four-inch pot, the bracts being small but well-coloured.

Messrs. Veitch had *Camellia Giannina Milli*, a pretty cupped white variety; *Filippe Parlatores*, carnation-striped on a bluish white ground; and *Giardino Santarelli*, the centre petals deep rose, and the marginal white; also *Dracena striata*, a highly ornamental foliage plant, especially the young leaves, which are of a bright pink; and *Hoteia japonica* with very ornamental spikes of small white flowers.

Messrs. A. Henderson & Co. had the lavender-flowered *Hebeclinium atro-rubens*; *Tropæolum Ball of Fire*, the flowers of which are of a splendid bright scarlet; and *Dracena cannæfolia* with immense dark green leaves. And Mr. Parker, of Tooting, among other things, contributed *Funkia univittata* and *Symphytum officinale* with the leaves deeply margined with pale yellow. *Phalænopsis Schilleriana* was exhibited by Mr. Williams, of Holloway, and Mr. Wiggins, each plant having a handsome spike of bloom, that on Mr. Wiggins's being the larger. Messrs. Lee, of Hammersmith had *Camellia Lavinia Maggi*, *Hermione*, a double white *Azalea* with here and there a carnation streak; also a box of cut Camellias.

FLOWER-GARDEN ANNUALS.

THE accompanying list of annuals has been sent to us for approval by a correspondent from Newport, Monmouthshire, and we append the remarks of a good authority; but we shall be glad to learn the opinion of others, as catalogues of annuals have become so extended of late, that it is possible many useful species may have escaped the notice alike of our correspondent and his adviser. We, however, give the list as sent us, followed by the notes that have been prepared on the subject.

- | | |
|---|---|
| 1. Asters—Dwarf Chrysanthemum-flowered and Giant Emperor. | 37. Marigolds—African and French, tall and dwarf. |
| 2. Athanasia annua. | 38. Mimulus cupreus. |
| 3. Asters—Bouquet. | 39. Nola alba. |
| 4. Ageratum mexicanum nanum. | 40. Oxysora. |
| 5. Anagallis, mixed. | 41. Oxalis tropæoloides. |
| 6. Arctotis grandiflora. | 42. Poppy—French, mixed. |
| 7. Browallia, mixed. | 43. Phlox Drummondii, mixed. |
| 8. Brachycome iberidifolium. | 44. Rhodanthe Mangelsii. |
| 9. Clarkia pulchella flore pleno. | 45. Stock—White wallflower-leaved, Ten-week, German, and Dwarf Bouquet. |
| 10. Chrysanthemum Burridgeanum. | 46. Salpiglossis, mixed. |
| 11. Calendula officinalis superba. | 47. Schizanthus, mixed. |
| 12. Centaurea gymnocarpa. | 48. Spraguea umbellata. |
| 13. Centa alba. | 49. Schizopetalon Walkeri. |
| 14. Campanula pentagonia. | 50. Silene armeria alba. |
| 15. Cotula aurea. | 51. Sabbatia campestris. |
| 16. Calandrinia umbellata. | 52. Viscaria, mixed. |
| 17. Calliopsis nigra nana. | 53. Zinnia elegans flore pleno. |
| 18. Calendula pluvialis. | |
| 19. Dianthus chinensis Heddewigii. | |
| 20. Erysimum Peroffskianum. | |
| 21. Eucharidium grandiflorum album | |
| 22. Feverfew, double white. | |
| 23. Gilia tricolor. | |
| 24. Gaillardia grandiflora. | |
| 25. Grammathe gentianoides. | |
| 26. Gypsophila muralis. | |
| 27. Heliphila araboidea. | |
| 28. Isotoma petraea alba. | |
| 29. Iberis umbellata. | |
| 30. Indian Pink, double white. | |
| 31. Iberis grandiflora alba. | |
| 32. Kaulfussia amelloides. | |
| 33. Larkspur, tall Stock-flowered (blue). | |
| 34. Leptosiphon, new French hybrids. | |
| 35. Leptosiphon densiflorus albus. | |
| 36. Lobelia speciosa. | |

Ornamental foliage.

54. Venus's Navelwort.
55. Crimson Orach.

Scented Annuals.

56. Mignonette.
57. Limnanthes Douglasii.
58. Abronia umbellata.
59. Cedronella mexicana.
60. Amblyolepis setigera.
61. Nemesis floribunda.
62. Centranthus ruber.
63. Scabiosa, dwarf scarlet.
64. Amberboa moschata and odorata.

Everlastings.

65. Helichrysum compositum maximum, mixed.

[It is no easy matter to take up a comprehensive catalogue of annuals of the present day, and give a decided opinion on what is really good. Many who grow flowering-plants on an extensive scale grow but few annuals. The mode of keeping half-hardy plants through the winter and propagating them in the spring has of late years been so much simplified, and is now carried to so much greater extent than it was years ago that, comparatively speaking, few annuals are grown on what is called the large bedding-out plan. Nevertheless annuals have their merits, and it is to be hoped some one better acquainted with them than I am will give us the benefit of his experience; but as most of those mentioned above are well known, a hasty glance at each will suffice. Additions thereto will be treated of afterwards.]

Commencing, therefore, in the numerical order they are placed in, we may say that Nos. 1 and 3 are good; 2, not known; 4, grows taller and flowers later than the same kind kept through the winter, and propagated in spring; 5, middling, only presents few flowers to look at in the distance; 6 is said to be good; 7, too tender in ordinary seasons for out-doors; 8, requires a dry soil; 9 and 10, both good; 11 and 13, varieties of *Marigold*, than which nothing looks better when they are good; 12, rather coarse; 13, not remarkable; 14, there may be some other *Campanulas* added as well as the one given—*Venus's Looking-glass* belongs to this genus; 15, not known; 17, 19, 20, and 21, all good; as likewise are 22, 23, and 24, all favourites; 25 is said to be good; 26, not remarkable; 27, good; 28, if resembling *Isotoma axillaris* it is good; 29 and 31, *Candytuft*, of which there are several good varieties; 30, also affords many useful varieties; 32, good; and 33, deservedly so, several varieties deserving attention; 34 and 35, good and hardy; 36, perhaps the best of all annuals, though not an annual either; 37, indispensable, sow several varieties; 38, requires rather moist ground; 39 and 40, good; 41, not much acquainted with; 42, good for shrubberies; 43, on a peaty or moist soil is very fine, but useless in dry places; while 44 is quite at home there; 45 needs no commendation; 46, I have never been successful with; 47, fine; 48, said to be good; 49, do not know the variety; 50, said to be good; 51, too tender for out-doors; 52, good and hardy; 53, good, the single is, perhaps, better than

the double; 54 is certainly wrongly placed; while 55 is inferior to *Perilla nankinensis*; 56 is good; 57, only slightly scented; 58, showy plant; 59, a stranger; 60, said to be good; 61, not known; 62, not much scented; 63, more remarkable for flower than scent; 64 are related to *Eschscholtzia*.

Although the above list comprises as many names as most small growers would care to have, there are, nevertheless, several other good annuals from which a selection could be made as useful and showy as that described above; and if we except the *Asters*, *Stocks*, and French and African *Marigolds*, there are four others omitted in the list that I would place before any that are in it. These are *Saponaria calabrica*, *Collinsia bicolor*, *Nemophila insignis*, and *Portulaca*. These seem to me so indispensable where annuals are grown, that I am surprised at their omission. Tastes, however, differ, and some one else may suggest others which may be thought still more deserving; but as my list is not yet complete, I may say, that in addition to those of which the names are already given, the blue *Convolvulus* is worthy a place. *Senecio elegans* and some of the *Lupinus* are also pretty; and *Delphinium chinense* as well as others is good. The double *Sunflower*, *Helianthus*, is also an excellent adjunct in the background; while *Virginian Stock*, *Scarlet Valerian*, *Bartonia aurea*, and some of the *Oenotheras* and *Godetias*, are all useful in their way. The dwarf and pretty *Clintonia pulchella* is also an acquisition, not less so being *Linum kermesinum* and others. The old *Eschscholtzia crocea* and others are rather coarse, but some admire them; and a bed of seedling *Petunias* lasts through the season well. *Venidium calenduleum* is also good; and, perhaps, the prettiest of all blue is a bed of *Salvia patens*; while *Lotus jacobaeus* and *Martynia fragrans* ought not to be forgotten. *Trachelium coruleum* is also deserving of a place everywhere. I believe some of the *Aquilegias* are good, but I have never been successful with them. Many other plants, however, might be added, but I leave the further extension of this list to other hands; I will however, mention a few having remarkable foliage which our correspondent has wisely placed in a class by themselves.

In the first place stands *Perilla nankinensis*, a plant much better than *Purple Orach*. Equal with this, but not so extensively grown is, I believe, *Amaranthus melancholicus ruber*; while in a like strain, though beautiful-flowering plants too, are *Lovelies-bleeding* and *Prince's Feather*. All these have a bronze-coloured foliage. In direct contrast with them is *Salvia argentea*, a white-leaved plant, woolly, and conspicuous. In the large-leaved class are some of the genus *Ricinus* or *Castor Oil Plants*. *Marvel of Peru* is also a singular-growing object, though not more pretty and graceful than *Canna indica*, or some of its kindred species. In a smaller way are some pretty *Grasses*, as *Stipa pennata*. The *Ice Plant* is also singular; as likewise is *Tobacco*, and the berry-bearing *Phytolacca decandra*, which, however, is very tall, though not more so than *Heracleum giganteum*; and I do not know that either of them excels a plant of the common *Hemp* for beauty of foliage. This list, however, may be extended so far as to become, perhaps, as numerous as the other.

In addition to the three classes given by our correspondent, he might have added a fourth for creepers, which would have been as interesting as any. *Cobaea scandens*, *Maurandya Barclayana*, *Eccremocarpus scaber*, *Tropaeolum peregrinum*, and some others are all useful; while *Sweet Peas* and some of the *Tropaeolums* are also indispensable—in fact, the dwarf varieties of *Tropaeolum* ought to have a prominent place in the list of flowering-annuals, which I find I have omitted. But it is a most difficult task to limit the number of species of annuals which different individuals might recommend; and supposing a person restricted the list to twenty, might I ask what would these be, omitting *Stocks* and *Asters*, which are every one's favourites? It is questionable if anything like unanimity would exist amongst the first ten persons that might be asked the question: nevertheless, the question is one well worth asking, as I confess my knowledge is far from being perfect in this matter.]

GARDEN ENGINE.

ABOUT this time last year I purchased from Mr. G. Heaven, High Street, Birmingham, a garden engine, price 9s. It throws a continuous stream to a distance of 40 feet, and is now, after twelve months hard work, as good as ever. The workmanship is rough, but there is not likely to be any

injury done to this engine which a tinman could not remedy. I was told that a Frenchman, too poor to take out a patent, was the maker.—E. H.

MESSRS. CUTBUSH'S EXHIBITION

OF HYACINTHS AND OTHER SPRING FLOWERS.

COCKNEY though I am, and born within the sound of Bow bells, 'Ighgate' ill had until last week been a *terra incognita* to me. I had never toiled up what to Londoners is, I dare say, quite a *Snowdon* or *Grassfjel*—had never admired the wondrous wit at which I suppose successive generations of citizens have laughed as they sat on those seats, where admonitions to take care of defacing them are graven with such laconic wit, that a man must be indeed bent on mischief who could do so; and even now I had not attempted the feat, had not frequent and pressing invitations from Mr. James Cutbush and my own love for the *Hyacinth* tempted me to do so. And although a correspondent has given his ideas on the subject already, I hope it may not be out of place to record my impressions of this Exhibition, so well worth the visit as it was to all who have a real love of flowers.

As *Hyacinth*-growers this firm has stood at the top of the tree for many years; and although I am not going to "reveal the secrets of the prison-house," I may say that these importations of bulbs from the first growers in Holland have during the past ten years increased twelvefold, so much more widely spread is the taste for floriculture, the stimulus to bulb-growing having been in no slight degree augmented by this very Exhibition of which I am now writing. I was quite assured of a kindly reception from Mr. Cutbush, and am indebted to him for a very pleasant morning spent amongst his spring flowers.

The greenhouse in which the display takes place abuts on the residence, and skirts it at two sides. As arranged for the Exhibition it is filled up with a stage, the back reaching up the back wall to within a few feet of the top, and with a broad shelf running round the front. The arrangement displayed considerable taste, and gave a very pleasant and bright appearance to the house. On the lowest shelf there was a row of double *Primroses*, yellow and lilac alternating. Above them was a row of the dwarf miniature *Rose* in nice bloom. Above that again a row of *Primulas* and *Mignonettes*, the *Cyclamen* on one side of the house taking the place of the *Primula*. Above that again a row of *Tulips* in pots, then a row of *Cytisus* and *Deutzia scabra* alternately; while the shelves above these were crowded with a gay mixture of *Azaleas*, *Camellias*, *Dielytra*, *Kalmias*, *Epacris*, *Cinerarias*, *Narcissus*, and other spring flowers—pots, stages, and all being hidden by the profusion of bloom and quantity of foliage. On the front shelf the *Hyacinths* were arranged, all being placed in 24-pots, and then covered with green moss gathered in Epping Forest. This plan has been adopted in preference to that formerly used of plunging the pots in moss, which was found to be too heating for the plants.

I have been anticipated in the lists I had taken of what seemed to be the most beautiful varieties; and I hardly think it is worth while again filling up space with a mere list of names, for there can be but very little difference of opinion as to what constitutes a good *Hyacinth* and what flowers come up most closely to the required standard. Many of the new varieties—and we must recollect that it will be years before these come down to the reach of ordinary mortals—cost two guineas, which is a large sum for a plant; but for a plant that only gives a good bloom once, and then must be consigned to the border, it is very high. And when we talk of improvement and the probability of something novel making its appearance, we must recollect that if a seedling be raised this year it will not come into general sale for nearly twenty years! hence we older ones must content ourselves with what we have, leaving to our juniors to look out for *Hyacinths* twice as large as anything we have now, and of all imaginable and unimaginable shades of colour. Mr. Cutbush informed me that of the beds of seedlings which he saw in Holland, by far the greater number were of that lilac shade of which *Haydn* and *Unique* may be considered as types—a colour more interesting to foreigners than to us, with whom I do not think it finds much favour.

I find that Mr. Cutbush's experience with the *Hyacinth* is the same as that of florists with every other flower, that there

are some seasons in which some kinds are especially good and others inferior—facts which are difficult to account for, but which are nevertheless true. He had told me that the bulbs were not so good this year as usual; but I am bound to say that I saw no evidence to that effect.

The collection of *Amaryllids* exhibited by Mr. Cutbush at the Show at South Kensington on the 18th were likewise in bloom, and finer bulbs I never saw; but the sorts generally wanted that breadth of petal which we consider necessary to form a first-rate flower, such as Mr. Williams's *Amaryllis Unique*. The treatment to which the bulbs had been subjected must have suited them very well, for they were of very large size and in full vigour of growth.

In the other departments of gardening Mr. Cutbush is making also great advances. The prevailing taste for Roses has induced him to erect a span-roofed house for the purpose of growing them and Vines. The stock looked uncommonly well, and contained all the best varieties of Roses. One is often tempted to ask what becomes of all the Grape Vines. At every nursery one sees that they are grown in great abundance, and all speak of them as selling well. Roses one can understand, but Vines are a different thing; and we must suppose that very few are left of the older plants, and that the new ones have taken their place. Bedding plants were also cultivated, and the usual assortment of nursery stock. I also noticed the, to me, interesting sight of a small beginning of a collection of *Auriculas*, grown not for sale, but as a little hobby of Mr. Cutbush.—*D., Deal.*

VENTILATING & WARMING HORTICULTURAL STRUCTURES.

THE articles upon this subject which have lately appeared in your Journal, are as highly instructive to the general reader as interesting to those whose knowledge enables them to understand the laws of aëration by the power of heat.

Having had much experience, and devoted much time to experiments in heating and ventilating, and having tried most of the systems for heating in general use for mansions, cottages, and horticultural structures, I have arrived at the conviction that the prevailing error is warming too much and ventilating too little. The great secret lies in combining the heating apparatus with a thorough ventilating system, and supplying a sufficient quantity of air, ever changing and circulating through the building at a proper temperature, without at the same time wasting in the chimney-flue more heat than is wanted to carry off the smoke and make the fuel combustible.

We can arrange a most economical and most useful heating apparatus for large establishments, by combining hot-water pipes with the *Polmaise*, or air-chambers having ventilating openings to regulate the quantity according to the change and perpetual alteration of temperature in the external air.

The public generally consider many of the newly-invented air-warming stoves, *Polmaise* and *Arnott's*, &c., to be failures. The principal cause why is, because the warm-air-chambers are too small to supply the proper quantity of air required to keep up the temperature, without overheating and destroying its life-sustaining properties. If we allow the air to take up the heat as fast as the fire gives it out, then the warm supply of atmosphere will not be burnt. It is through confining it too long in a small hot chamber that it becomes exhausted, and its properties destroyed. When the space required to be warmed is rightly apportioned to the apparatus employed, the air absorbs the heat as fast as it is generated without destroying the atmosphere. If we understand this rule we can use any system of heating for ventilation. Every living thing requires fresh air, plants as well as animals. Nature has provided sufficient for us all, and supplies it abundantly to the doors of the mansion, cottage, or other erection; but with doors and windows we try to keep it out, because the air in our climate is cold and damp, and, rather than admit it in that state, we try to live as long as we can in impure air, for the sake of comfort in our dwellings. To make air life-sustaining and healthy, depends upon ourselves. Cold or warm air has the property of supporting life, if it be good; but bad air destroys life. Air in circulation promotes health; but in a state of stagnation breeds disease.

The exhibitions of plants, from time to time, prove that when care is taken by the cultivator in this country he can imitate the temperature of our climate, and show clearly that heat properly

combined with air produces exotic plants equal to those of their own native homes, which are warmed by the sun. To be uniform in success will depend upon our power of assimilating an artificial atmosphere suitable to the wants of the nurslings in our conservatories.

This is a question that now requires more attention than it has hitherto received; and it is evident that no system of ventilation, unless combined with heating, can in this country provide what is wanted—that is, the knowledge how to make a comfortable and healthy artificial climate in our dwellings. A nobleman some years back, on observing my process of heating conservatories, addressed me thus—"I want you to make the climate of Italy in my own house. I cannot go to that country, but I desire its genial atmosphere." I carried out this order, not by shutting the air out, because had I done so we should have had no substitute for its healthful motion. Heat we could have, it is true; but heat is not air, and if we stop out the air we have nothing to warm. It was then and there I first adopted my plan.

We meet with people daily who are fitting-up heating apparatus, but who are not ventilating, without the slightest idea that such is the fact. I met a gentleman in the International Exhibition, 1862, who, like myself, was studying what was exhibited there as likely to be useful in the way of warming and ventilating. He told me he had been employed upon nothing but heating buildings for the last thirty years. He had fitted up 3000 apparatuses, but never combined ventilation therewith, only because he did not understand it. He could heat a building to any degree of temperature required; he wanted ventilation, but could not see anything in London worth coming from Leeds to examine. This statement was confirmed after the closing of that Exhibition; for if we refer to the Jurors' Report of Class X., Section B., Sanatory Improvements and Constructions in the International Exhibition, 1862, they say—

"As a general result it does not appear that the active thought stirring among men is in sanatory contrivances very great. The amount of education on the subject is still deficient, and all progress must be slow until the nation is brought up a little farther. There is, in fact, a desire for change, in some instances to the worse, from an ignorance of the past we have left behind. New ideas of a purely sanatory kind we have absolutely none before us. Although since 1851 the subject has grown widely, we know more of the condition of the air, more of the necessity of ventilation, and more of its difficulty; but the progress of our knowledge has not been seen in the Exhibition. Thus far we see a defect in it; the whole circle of human invention has not been exposed to view, and room is made for improvement in a future exhibition. Although we have not shown all that has been done, we must not forget that much is still undone. We have not learned the best mode of ventilating; we cannot warm and ventilate a small room so as to make it healthy and comfortable. The response in the Exhibition has not been so great as the intellect of the country led us naturally to expect.

"The great demand in this country is for warmth and dryness. Give these, and we are ready to ventilate sufficiently; deny these, and the whole population instinctively prefers bad air to cold-giving air: therefore if we ventilate sufficiently, we must warm."

There cannot be any question about there being room left for improvement, and for producing a better system of ventilating, combined with warmth, if we intend to convert the natural atmosphere into an artificial and healthy climate in-doors. Persons in the habit of attending horticultural exhibitions have frequently the opportunity of seeing prizes of flowers, fruits, and vegetables obtained by cultivators having no better systems of warming than the smoke-flue; but good gardeners understand how to assist Nature without doing her violence, and avoid going too fast with heat without plenty of air. Nevertheless, experience in horticulture convinces me that more information upon this point might be obtained if our horticulturists would set about ventilating and warming buildings to feed the plants, by supplying air as they have set about other departments of agriculture and horticulture, as, for instance, in manuring, or in thorough drainage.

To be further useful, and to meet the requirements of the poor, I have fitted-up a room to show how the common house stove can be converted into a fuel-saving, smoke-consuming, heating-and-ventilating apparatus, without costing more in the first construction of the building, but effecting a vast saving of fuel. Since I have shown this system to my friends, several have adopted it with much satisfaction. I have had an apparatus made for J. Walter, Esq., of Bearwood, for a national school he has just built at Sandhurst, near Wokingham, at his own expense. This plan can be seen in daily operation at my residence upon application.

What is wanted just now is the combination of practically-informed men to co-operate, to give publicly an account of what may be done; and this is most essential if we are to

put in a better appearance at any future exhibition. The Horticultural Society having appointed an implement committee to report upon heating and ventilating apparatus, I hope they will find out something new and more useful. I hope that this subject will before long be considered of such importance, that it will be taken up by a sufficient number of persons to make an instructive and interesting Society, to be called "The London Warming and Ventilating Associates' Society."—JOSEPH NEWTON, 30, *Eastbourne Terrace, Hyde Park.*

APRICOTS FAR NORTH.

A CIRCUMSTANCE to which I shall afterwards allude has impressed strongly on my mind, that the most satisfactory mode of cultivating the Moorpark Apricot (at least in the northern part of the kingdom), is by flued walls, or some analogous method of imparting heat without covering. In such gloomy, cold seasons as 1862, the tree is not able either to ripen the

fruit or to form flower-buds for the following crop without some such help; and in this neighbourhood, even in the most favourable situations, the Apricot trees are this spring almost destitute of blossom.

The wall of my kitchen containing the chimney, which, of course, is in constant use, is one of the boundaries of my property in this small town; and my neighbour, whose back court immediately adjoins, has availed himself of a right to nail his trees on my wall. He has just informed me that on an Apricot tree planted on that part of it behind my kitchen fire he has a most abundant crop, beautifully set, while on another tree at a short distance on the same aspect (west) there are very few blossoms. It occurs to me, that what the Apricot wants is heat sufficient to ripen the wood, stimulate the formation of flower-buds, and ward off spring frosts. The same agency when the summer is backward, will promote and insure the ripening of the fruit. It would appear, I think, that the tree is rather impatient of glass and close covering.—J. F., *Haddington.*

SMALL FLOWER GARDEN.

For this year I think of having No. 8, Purple King Verbena; Nos. 4, 5, 11, 12, yellow Calceolaria; 7, 9, plain-leaved Scarlet Geranium; 2, 14, Flower of the Day, mixed with Perilla or Veitch's *Amaranthus melancholicus*; 1, 3, 13, 15, Flower of the Day, mixed with blue Lobelia; 6, 10, *Koniga maritima*, mixed with blue Lobelia.

The above plan is only one-half of the garden. A walk 8 feet wide, edged with 5 feet of grass, divides the two beds No. 10, so that there is a corresponding arrangement on each side of the walk.—P. M. P.

[Your plan of planting will answer very well, and those beds of one colour we think you will like best. In another season you will gain variety by edging the beds. Your present principle of planting is centering, balancing, and a little cross-planting, and its simplicity will be its chief charm. The centre bed is of Purple King Verbena; and the eight beds round it are four of yellow Calceolarias, and two of the larger in Scarlet Geraniums, and two of Flower of the Day, mixed with Perilla or *Amaranthus melancholicus*. We did not find this *Amaranth* succeed well with us, and the Perilla will be too strong unless stopped very early, and so kept down that the little twigs shall mingle with the Flower of the Day. So used, the purple Spinach will also do well, and it makes with the Flower of the Day a nice soft bed to the eye.]

Your four corner beds, 1, 3, 13, 15, you propose to be mixed beds of Flower of the Day and blue Lobelia. We should have preferred something else variegated—as *Manglesii* Geranium, as your Flower of the Day will run in lines—as 1, 2, 3, and 13, 14, 15. The *Lobelia speciosa* or *L. erinus* will be too low for mixing with the Flower of the Day, unless the plants of the latter are small. If you retain Flower of the Day for these four beds, we would not mix but give a nice edging of *Lobelia speciosa*, with an outside single row of *Cerastium* next the grass. Something of the same objection appears to the two ends of your figure 3, 10, 15, 1, 6, 13, as the prevalent character would be white and blue.

We are doubtful if punching-out, as it were, 6 and 10 adds to the completeness of your figure. At any rate, if using 6 and 10, we would not employ variegated Alyssum and blue Lobelia, when their neighbours 3, 15, and 1, 13, were Flower of the Day and Lobelia. If we retained the Alyssum and wished to mix, we would use the soft lilac of *Verbena pulchella*, or *Verbena Charwoodii*. In either case the Verbena and Alyssum would be matched for strength. Nos. 6 and 10 would also do well if filled with crimson Ivy-leaved Geraniums, with an edging of Golden Chain. One charm of your little garden will consist in the good space you give between the beds.]

ERIDES MACULOSUM, VAR. *SCHROEDERI*.

Description.—An epiphytal herb with broadly strap-shaped, obtuse, and deeply emarginate oblique leaves, and a pendent, open, many-flowered panicle. Flowers very delicate, the sepals and lateral petals almost alike, obovate and obtuse, spreading, white tinged with lilac, and spotted with lilac rose. Labellum consisting of a pouch-like base, prolonged downwards into a slender arched spur, bordered above by a small tooth on each side, between which is a bifid tubercle; the middle lobe of the lip is, at first, suddenly expanded, then contracting from an angle on each side to a somewhat obtuse point, forming, thus, a narrow triangular-rhomboid limb, with the sides deflexed; the middle lobe pale lilac marked with rose, deepest at the base; the spur gradually shaded into bright yellowish-green.

History, &c.—This plant seems to bear a close resemblance to *Erides maculosum*, from which it can hardly be specifically distinct, although in the shape of the lateral teeth of the lip, and in the bifid tubercle between them, it appears to differ slightly. Considering the much greater difference between the other species, we prefer to regard this as a variety.

—A. H.

For an opportunity of figuring this very beautiful plant we are indebted to J. H. Schröder, Esq., of Stratford Green, Essex, in whose unique collection of Orchids it has blossomed several times, and by whom the following particulars are supplied:—"I purchased it at Mr. Stevens's sale, Covent Garden, being part of a small importation from the hills near Bombay. My attention was directed to it by its very distinct habit, and the remains of a flower-spike from every leaf. We have flowered it now for three years, and each year finer than the preceding, and should we be fortunate enough to attain its

native flowering habit, I need not say what a magnificent thing it will be. It appears to be a hybrid between *Erides crispum* and *maculosum*, and on that account I value it the more, as I do not think it is so likely to be introduced again."

Culture.—The following is the treatment recommended by Mr. Goode:—"The plants belonging to this lovely genus, to grow them to perfection, require to be placed, in the growing season, in the warmest and most humid part of the Orchid-house; and, in addition to the moisture suspended in the atmosphere, to be liberally syringed daily with tepid soft water. When, however, the plants are first imported, they must be thoroughly washed, both root, branch, and foliage, for until they are cleared of all kinds of filth it will be found impossible to grow them to anything like perfection. Rustic baskets, or pots with perforated sides, are the most suitable to grow them in, and the compost used should be very fibrous peat and sphagnum moss, liberally intermixed with charcoal in large and small pieces; press the compost close together, and to make sure that the plants are firm in the pots, use a few pegs to hold the soil together. Suspend the pot or basket close to the glass, and take care to keep a mild atmosphere at all times, and the plants when once established will then grow with great freedom. Water liberally, and shade in very sunny weather, and take care that the plants are not broiled by a too free admission

of air in immediate contact with them. When the growth is completed, and more especially after they begin to show bloom, they may be kept comparatively dry, but they must not at any time be subjected to a low temperature.—(A. in *Gardener's Magazine of Botany*.)

EDINBURGH HORTICULTURAL SOCIETY.

THIS Society held its first Exhibition of flowers and fruit for the present year on March the 18th, in the Music Hall, George Street. The striking contrast with regard to the weather which marked the present occasion, as compared with that which occurred at the first Exhibition last year, affords a striking proof of the fickleness of our climate. Last year it was a day of cold drizzling sleet and rain; on this occasion, although ushered in with a pinch of frost, the day was all that the most fastidious could wish for in March—a day of calm and sunshine. On such conditions depends to a large extent the success of a flower show, both in a financial point of view to the Society, and to the public in the amount of pleasure and instruction afforded by the inspection of so many of Nature's gems, and the intelligent skill which such meetings bring together. The collections of plants, and particularly Hyacinths, though less numerous than on some former occasions, particularly that of last year, were abundantly numerous and first-rate in quality, and afforded a most enjoyable feast of floral beauty to the perfect crush of the élite of Edinburgh and its environs which thronged the hall both afternoon and evening.

Before passing on to notice in detail the objects which were exhibited, we cannot refrain from expressing great regret that several of the leading nursery firms did not contribute a single object on this occasion. This, of course, told to some extent on the general appearance of the Exhibition, although the more than usual excellence and number of objects contributed by private growers, and one or two of the Edinburgh firms, fortunately

served to make up for the absence of those whose interest we would suppose it was to contribute on such occasions. There was nothing from the gigantic concern of the Messrs. Lawson, of Golden Acres, nothing from the Messrs. Dickson & Sons, next to nothing from Mr. Methven, of Leith Walk. Surely this is not to be their rule on future occasions, as none we conceive have more inducement to contribute to the prosperity of a horticultural society, nor more interest in fostering and fanning the love of flowers and fruits. Nothing but emulation and the exciting influence of competition could have brought gardening to its high state of perfection: withdraw this influence, and we would venture to predict a speedy flagging of the pace of improvement. Nor is this principle by any means confined to the science of culture; it is alike applicable to the existence, health, and vigorous action of societies. Let us hope that these great nursery establishments will in future see matters to be as we have indicated, and that our next Show at the same place will be favoured with their aid to a liberal extent.

Messrs. Carstairs & Sons contributed a unique collection of flowering-plants such as they grow for sale, which occupied the whole of a table which stretched entirely across one end of the large hall. It consisted chiefly of forced Geraniums, Azaleas, Cytisus, Camellias, Lily of the Valley (exceedingly well grown), Fairy Roses, Cinerarias, Kalmias, a large number of well-grown Hyacinths, and other bulbous plants, some half-dozen very chastely got-up bridal and hand bouquets. Altogether this was a most creditable collection, and had a fine effect at the end of

the hall, and well deserved the special award which it received from the Judges.

Messrs. Downie, Laird & Laing also had a very handsome table of plants, among which were conspicuous the beautiful *Caladium Lowii*, evidently the best of its class, Ferns, Lycopods, Hyacinths, Begonias, Marantas, some large pyramids of Azaleas (one of them that most beautiful white variety, Mary), and Dracenas, Cinerarias, and two specimens in a pot of the lovely and most useful decorative plant *Centaurea ragusina*. To this collection a special award was also given.

Messrs. Cunningham & Fraser also received a special award for a collection of beautiful Amaryllids, among which we noticed *Linnæi*, *Vittata major*, *Imantophyllum miniatum*, *Ackermanii*, *Solandraeflora*. The Amaryllis is a plant well worth far more attention than it has yet received as a winter and spring flowering bulb.

Mr. C. Alexander, of Larkfield Nurseries, contributed a table of beautiful Ferns in excellent condition for March. Mr. Methven had two large plants of *Dicksonia antarctica*, or tree Fern, which had an imposing effect—standing prominently above the other plants. We hope next season he will contribute some of the splendid Azaleas and *Rhododendrons* for which his establishment is celebrated.

Among new plants, by far the most striking was the lovely seedling *Rhododendron* Countess of Haddington, exhibited by Mr. Lees, Tynningham Gardens. This is a real gem, being a cross between *Ciliatum* and *Dalhousie*, and having the stiff compact habit of the former with a vastly superior foliage, and the sweetness and beauty of the latter. For spring decoration this must prove one of the very best things recently raised. It was awarded a special prize.

There was a quantity of seedling Cinerarias exhibited by Mr. M'Millan, gardener to J. Gibson, Esq., Woolmet, all very pretty, but not equal to varieties already in cultivation. Mr. Cumming, Newbyth, had also a lot of seedlings of this popular spring flower. One white variety among them was commended by the Judges for its dwarf and compact style of growth.

For the twelve finest Hyacinths—Gardeners and Amateurs—(we are sorry to say there were no competitors for the prizes offered to nurserymen), Mr. Reid, Grange Cemetery, was placed first with fine plants of *Seraphina*, *Miss Nightingale*, *Baron von Tuyl*, *Von Schiller*, *Charles Dickens*, *Grandeur à Merveille*, *Madame Hodgson*, *Mimosa*, *Mrs. B. Stowe*, *Alba Superbissima*, *Monsieur de Feasch*, *Robinson*. Mr. Henderson, Millbank, made an excellent second. His collection contained different from that of Mr. Reid's—*Lord Palmerston*, *Mont Blanc*, *Queen Victoria*, *Lord Wellington*, *General Havelock*, *Macauley*, *Grand Lilas*. Mr. Vair, Gogar Bank, was third with such a collection as made it difficult for the Judges to decide the question.

For the best six.—Mr. Brunton, Duncleffe, was first with *Von Schiller*, *Alba Superbissima*, *Miss Nightingale*, *Prince Albert*, and *Lord Wellington*. Mr. Bery, of Newington was second; and Mr. James Watt, Broughton Park, third, with very good specimens.

Best six Hyacinths (Amateurs).—First, Mr. M'Phail, Athole Crescent; second, Mr. Young, South Bridge.

Best six Hyacinths in glasses (Amateurs).—First, Mr. Young; second, Mr. M'Phail.

Best six Hyacinths in glasses (Ladies).—Mrs. Nelson, Salisbury House.

Best single Hyacinth in the room.—Mr. J. Vair, Gogar Bank. The best double, Mr. Henderson, Millbank.

Four pots *Narcissus*, four pots *Tulips*, four pots *Crocus* (equal).—Mr. Vair, Gogar Bank; and Mr. Henderson, Millbank. Both these collections were exceedingly well got up, and formed a very attractive feature of the Show.

Twelve finest pots hardy spring bulbs.—Messrs. Cunningham and Fraser, Comely Bank Nurseries.

Twelve finest *Rhododendrons*.—First, Messrs. Cunningham and Fraser; second, Messrs. Dickson & Co. In these collections we noticed fine specimens of *Grand Arab*, *Pasithea*, *Prince Camille de Rohan*, *Jacksonii*, *Atrorubrum*, *Dalhousie*, *Etendard de Flandre*.

The finest scarlet *Rhododendron*.—Mr. Henderson, Millbank. The finest white *Rhododendron*.—First, Mr. Henderson, Millbank; second, Mr. Lockhart, Arniston.

Two Azaleas Indica.—First Mr. Henderson, Millbank, with two unique plants of *Iveryana* and *Criterion*. To the best of our recollection Mr. Henderson has taken first prize with not only these two varieties, but these two very plants for the last four

years, and this shows how certain a cultivator he is. Mr. Lockhart, Arniston, was placed second with well-managed plants, *Roi Leopoldii* and *Iveryana*.

Two finest *Epacris*.—A second prize was awarded to Mr. Fowler, Mavisbank.

For Cape Heaths there was no competition.

Three finest Cinerarias.—First, Mr. Henderson, Millbank, for Duke of Cambridge, Constance, and Glory of Dulwich; second, Mr. M'Millan, Woolmet, for Blue Bonnet, Brilliant, and an unnamed seedling.

Two finest greenhouse or stove plants.—First, Mr. Lockhart, Arniston, for *Erica Sindriana*, and *Pultenaea subumbulata*; second, Mr. Henderson, for *Acacia Drummondii*, and Azalea *Empress Eugénie*.

Six *Camellia* blooms.—First, Mr. Henderson, with very fine blooms of *Candidissima* *Halleyi*, *Abbey Wilder*, *Elata*, *Maria Theresa*, *Duchess of Buccleuch*; second, Mr. Lockhart.

The best Table Bouquet.—First, Mr. M'Millan, gardener to J. Gibson, Esq., Woolmet; second, Mr. J. Gordon, Niddrie.

Best Hand Bouquet (Nurserymen).—First, Mr. John Fraser, Rosebank; second, Mr. C. Alexander, Larkfield Nursery.

Best Hand Bouquet (Gardeners).—First, Mr. Henderson, Millbank; second, Mr. M'Millan, Woolmet.

Two best plants *Mignonette*.—First, Mr. M'Millan, Woolmet; second, Mr. Lockhart, Arniston.

Three best pots *Lily of the Valley*, three best pots *Violets*.—Mr. Reid, Newhailes.

Three best forced *Roses*.—First, Mr. Gordon, Niddrie, for *Gloire de Dijon*, *Géant des Batailles*, and *Coupe d'Hébé*.

Two best single *Primulas*.—First, Mr. Fowler, Mavisbank. A special award was made to two exceedingly well-grown white *Primulas* from Mr. Henderson, Millbank, which were disqualified from competition on account of their being both white, instead of one red and one white, as specified in schedule.

Four *Azalea Indica*.—First, Mr. Lockhart, Arniston, with good plants of *Magnificans*, *Fildertii*, *Stanleyana*, and *Symmetry*—all first-class varieties.

Twelve plants for table decoration.—First, Mr. Thomson, Dalkeith Park, with fine plants of *Cordylina indivisa*, *Pteris umbrosa*, *Grevillea robusta*, *Adiantum formosum*, *Colens Verschaffeltii*, two *Dracena terminalis*, two *Croton angustifolium*, two *Dracena ferrea*, and *Yucca variegata*; second, Mr. Fowler, Mavisbank, with three Azaleas, two *Ardisia crenulata*, two *Epacris*, one *Acacia Drummondii*, *Dendrobium nobile*, a *Pultenæa*, and a *Cineraria*.

Six finest *Azalea Indica*.—First, Messrs. Downie, Laird and Laing.

FRUIT.

The finest bunch of Grapes.—First, Mr. Thomson, Dalkeith, with a handsome and well-preserved bunch of *Lady Downe's*. Mr. Lockhart, Arniston, made a capital second with a fine bunch of the same variety, which had been cut from the Vine for fourteen days.

An enormous bunch of *Raisin de Calabre* was exhibited from Dalkeith. It weighed $4\frac{1}{2}$ lbs., and was without a shrivelled berry. This is one of the most valuable late-keeping Grapes in cultivation, and is the best white partner for *Lady Downe's* in spring yet out.

For the best thirty-two Strawberries, Mr. Gordon got a first prize.

From Archerfield Gardens there was a *Pine Apple* of the *Hurst House* Seedling not quite ripe, in an eight-inch pot. This variety is remarkable for its compact dwarf growth, and the large fruit that it throws in a small pot. A first prize was awarded to Mr. Thomson, Archerfield, for a moderate-sized fruit of the same variety.

VEGETABLES.

For the finest collection of vegetables, Mr. Gordon, Niddrie, was placed first. His collection had Asparagus, French Beans, Mushrooms, Sea-kale, &c. Second, Mr. Thomson, Woodburn.

Twelve heaviest stalks *Rhubarb*.—First, Mr. Vair, Dulock; second, Mr. S. Dickson, Whitehill.

Six finest heads *Sea-kale*.—First, Mr. Gourlay, Musselburgh; second, Mr. Fowler, Mavisbank.

Three *Broccoli*.—First, Mr. Scarlett, Rosebank; second, Mr. Gordon, Niddrie.

Six *Leeks*.—First, Mr. Fairley, Henderson Row; second, Mr. Thomson, Woodburn.

Finest *Pint Mushrooms*.—Mr. Pender, Moredun.

BEEES IN MY ORCHARD-HOUSE.

Sunday, March 22.—What a glorious sunny day! How filled is the air with the harmony of birds! The blackbird, the thrush, the chaffinch, and, above all, the lark, are pouring forth their thanks for this foretaste of spring. Well, as is my custom after morning service, I strolled into my orchard-house, and to my surprise—for, since the winter of 1860 which destroyed all the bees in this neighbourhood, so that I am not cognisant of a single hive—I found it literally full of bees, every tree loaded with its glowing blossom had from ten to twenty of these sabbath-working little fellows all busy in apparently gathering nothing but pollen, although, I dare say, they now and then stole a sip of nectar. As soon as two large lumps of the golden dust were glued to their thighs they took their departure home—heaven knows where, and then came every minute fresh arrivals to join in the loud hum of happiness and content. I almost fancied they thanked me for giving them such an early feast; and, then, how fearless they are, alighting on a flower close to one's eye, and allowing one to watch every movement without betraying the least feeling of anger or discomposure. There is something in all this very charming, the stillness of the Sabbath thus agreeably broken by the pleasing sounds of bird and insect life.

That I am not alone in my train of thought, allow me to illustrate by quoting from a note just received from one who is at the head of the scientific world, one whose mind is so gigantic in its grasp as to be able to people the world of countless ages past with its inhabitants. May I, therefore, trespass so far as to give an extract from the note in question?—"I have been sitting in my orchard-house surrounded by the loveliest bloom, with the sun shining warm at my back, amidst the hum of bees. One hour of enjoyment of such precocious summer repays the whole year's care. To ears wearied with the din of town, to other senses offended with its fog and fumes, to the mind jarred by the inevitable conditions of official responsibilities and intellectual struggles, you may conceive the paradise of such a contrast as I am now enjoying. A Sabbath peace, broken by the pleasing songs of happy birds, and the distant call of the rook; all the worlding's world shut out. But you cannot appreciate the scene without seeing it; and the full enjoyment of my garden will be wanting until you have an afternoon with me in it."

Such are the reflections of a man of high intellect—how different from those of the prize-looking-for gardener!

I begin to think that orchard-houses are far more adapted to the refined and philosophical, than to those who calculate how many fruit each tree will produce, and if they will be able to "show" at some horticultural exhibition. What lover of his trees could bear to strip them to make-up "dishes" of fruit, or send his beautiful trees, loaded with their fair produce, some miles at the risk of every leaf and fruit being bruised, and the beauty of the tree destroyed? No amateur or real lover of gardening would risk this. I have sometimes been half tempted to send two or three of my finest trees, merely to silence those detractors and persons of confined ideas who think everything worthy of being seen should be exhibited; but I have never had the courage, feeling assured that a fine tree of fruit must be destroyed, however carefully packed, during a journey of sixty miles. Exhibiting gardeners know little of the feelings of the real lover of orchard-house culture, who enjoys his house nearly at all seasons; but if there be any difference in the measure of his enjoyment it is in spring, when the trees are in full bloom; and he looks at them, not as he looks at his wall trees, with a mixture of hope and fear—the latter largely predominating—but with a calm, delightful, confident feeling that nearly every flower will produce a fruit, and that the only trouble he looks forward to is thinning it. The climate, also, of the orchard-house, irrespective of the fruit it gives and ripens, is a source of great pleasure. I often hear from friends, who are victims to pulmonary disease, expressing the pleasure they derive from the climate of their orchard-houses. It is, indeed, at all seasons—except in bitter dark weather, when there is not a gleam of sunshine for days—perfect. In the bright sunny weather we have had for some days past, the thermometer has stood at 72° in my large house, but the ventilators at a low level, admitting two large volumes of air, made the climate like that described by the Persian poet—"The warmth was not heat;" and, I may add, in cool weather, "Its coolness is not cold." Think of this, Mr. Robson, and repent.

March 27th.—I have just paid my morning visit to my orchard-house. The trees never were more magnificent. The most striking are those with large flowers, and first among them

are the Orange Nectarines, the Pitmaston and Rivers's Orange; the latter has the largest flowers and is really gorgeous. Next to these are the varieties of Grosse Mignonne Peaches, all bright and beautiful. Then we have the Shanghai, Montagne Précocée, Early Victoria, and Early York Peaches, and the Hardwicke Seedling, and Early Newington Nectarines, all with large and showy flowers. Among those with small flowers there are some varieties almost petalless, or apetalous, to use the botanical term: the Petite Mignonne Peach is remarkable for this. Others have small petals so bright and pretty that one is always arrested by them. Such are Impératrice, Downton, Violette Hâtive, and Elruge Nectarines, and the Violette Hâtive Peach. Besides these there are many intermediate flowers, scarcely two alike in the orchard-house, unless of the same variety. The effect may be imagined when I state, that there are more than four hundred trees, three hundred of which are Peaches and Nectarines, in my house in full bloom.

Pears, Cherries, and Plums with their pearly blossoms contrast so beautifully with the bright pink of the Peaches and Nectarines, as to make the picture perfect. My largest trees are now from ten to fourteen years old; and although their roots, to use Mr. Robson's phrase, are "cramped in pots" (oh! Mr. R., they are in the most perfect and vigorous health), the Apricots are all off bloom, and have set their fruit so thickly as nearly to hide the leaf-buds. I counted seven fruit in a square inch of space, and yet such men as our nonprogressive friends, Jasper Standstill and Peter Heavyhead, say that Apricots are difficult to cultivate as house trees. I cannot help saying "pooh."

I am fearful our friend Mr. Robson will feel a little nervous irritation in seeing this, to him, disagreeable words "orchard-house," at the head of this article.—T. R.

WORK FOR THE WEEK.

KITCHEN GARDEN.

AFTER the favourable weather for out-door operations which we have lately experienced, all kinds of work here should be in a forward state. Take advantage of the dry condition of the ground to get manure wheeled upon quarters where it is wanted, and to push forward any jobs which may involve wheeling. *Beans*, earth-up growing crops, and continue sowing for succession. *Broccoli*, sow for a main crop. *Cabbage*, sow for a main autumn crop. Fork up the earth between those planted in the autumn. *Capsicums*, pot-off as soon as they are fit. *Cauli-flowers*, stir the soil round those under hand-lights, and earth them up. Sow for autumn crop if not already done. *Cardoons*, sow seed if that vegetable is esteemed. *Celery*, prick-out the early crop. *Potatoes*, plant the main crop. *Spinach*, sow small crops of the Round in drills, but little at a time, as it soon runs to seed. *Tomatoes*, these should now be potted-off. Sow seeds of herbs and other vegetables that may have been omitted during former weeks. Remove all litter and weeds. Earth-up early crops, strewing a little soot or fresh lime about them to prevent the attacks of slugs. Protect recently-sown seeds from birds by a covering of nets, or by twine stretched over the rows or beds, with pieces of glass suspended from it in a manner to clash with the wind and to flash with the sun.

FLOWER GARDEN.

All nature is now starting vigorously into life; and, however delighted we may be by looking on the productions of genius, no art can inflame our sensibilities like the glow we feel coming over us on viewing the universal mind of the Great Designer unfolding itself in every leaf and flower; and, instead of the sigh of despondency coming over us, we should feel that this is a season of the year to be joyful, and to be ready at all times to respond to all the animate and inanimate expressions of nature about us. Prosecute vigorously, till finished, improvements in this department. Bring speedily to a close the laying-down of turf and the planting of deciduous and evergreen shrubs. Make a sowing of all the showy hardy annuals in the flower garden and shrubbery borders. Pay due attention in sowing to the heights and the arrangement of colours. Gravel put on walks, especially if sloping, should be almost in a state of mortar prepared for use; well trodden and afterwards rolled, it forms a hard and durable walk. To keep Ivy close to a building, it is advisable to defoliate it about this time, and it will soon again be covered with fresh and vigorous leaves. Continue to put in cuttings of those choice

varieties of Dahlias of which it is desirable to have a good stock. Sow choice Ranunculus seed in shallow pans or boxes; cover the seed as lightly as possible, and place them in a cool frame. This is a good time to strike cuttings of Fancies; put them in round the sides of small pots, plunge in sand on a north border and cover with a hand-glass.

FRUIT GARDEN.

The season for disbudding fruit trees is fast approaching. The importance of this operation is generally acknowledged, and upon its proper performance mainly depends the production of a proper quantity of clean healthy wood of the best quality. Every tree in a good soil is capable of producing and bringing to perfection that quantity of wood and number of fruit which is proportionate to its age and the healthy condition of its roots: consequently, if by carefully thinning the fruit, and removal of superfluous shoots, the fluid is directed to all parts of the tree at nearly equal distances, the result will be that each shoot will have the power of drawing to itself that amount of sap which is necessary for its healthy support. Employ all available means of affording efficient protection to early wall trees. Whatever material be employed it should be devised that it may be speedily removed at will, to allow the trees the advantage of fine weather.

STOVE.

Here at this time much is to be done in the way of timely potting, and applying weak manure water to those plants now making their growth and filling their pots with roots. Shut-up a high temperature rather early in the afternoon, and use the syringe liberally.

GREENHOUSE AND CONSERVATORY.

The great proportion of greenhouse plants are now in activity, and very much depends on the treatment they receive at this time. The practice of dwarfing trees, shrubs, &c., which the Chinese pursue with such assiduity, is diametrically opposed to our method, which generally consists in developing things to their utmost power of expansion; yet, admitting the absurdity of a fashion that would strive against Nature, we might, nevertheless, profit by a lesson from them when, restricted in space, we are yet compelled to retain a certain number of decorative greenhouse plants, which, if permitted to increase in size, would occupy an unfair proportion of the plant-house. It becomes then necessary to adopt the Chinaman's custom, and restrict those circumstances that conduce to luxuriant growth; and in some cases, still following his practice, use the pruning-knife to both branch and root, to adapt the unfortunate subject to the limited accommodation. This is a trying period for the conservatory inmates, at least for those of delicate habit, and a slight shading may not be amiss for an hour or two on very sunny days. See that twiners which are starting into growth are kept free from insects, as these, if allowed to gain a footing upon the young tender shoots, will soon do a vast amount of mischief. Large plants of *Brugmansia* that have been kept dry and resting through the winter should now be pruned back, shaken out and repotted in readiness to be turned out of doors in a sheltered situation, where they form beautiful objects in the late summer and autumn months.

PITS AND FRAMES.

At this period it is of much importance to have a dung-bed or two of a very moderate character fitted-up for the purpose of cooling-down fresh-struck cuttings, hardening annuals, and receiving plants from either the stove or the greenhouse; for, in consequence of liberal shifts in these departments, and the rapidly increasing size of *Cinerarias*, *Pelargoniums*, &c., something will of necessity have to be removed, and a cold frame is insufficient for some of these tribes. Look well to the propagation of bedding-out plants. See that such climbers as *Rhodochiton*, *Maurandya*, *Lophospermum*, *Tropæolums*, &c., are propagated and cultivated for blanks or trellising, &c. W. KEANE.

DOINGS OF THE LAST WEEK.

AND such a glorious week for March dust, which the old proverb tells us is more valuable than gold dust to the community, and more valuable even to the agriculturist than to the gardener, as the farmer gets in now the greater part of his seeds for the season, whilst the gardener must sow only a little bit of many things at a time, to keep up a continuous fresh supply. Of course, there is a main crop of Onions to be sown, and the

weather was so tempting that we sowed a good portion of them, and a first instalment of Carrots, and just a little bit of Beetroot to come in early. Where young Onions are a desideratum there must, as with us, be a sowing at least every month during the summer, and young Carrots are so much sweeter and so much less likely to be affected by the worm, that several sowings up to June, and again a few Early Horns in September, will enable the gardener to keep on better terms with the cook, just because of the reaction of commendations of everything being "so nice" from the dining-room. April is generally early enough for Carrots, and the end of April quite time enough for Beetroot, Salsafy, &c., but a few heads of forward Beet are useful, even should a part of it run. Threw a little lime and soot over the Carrot and Onion ground, to keep worms and slugs at a distance. Placed spruce boughs, from which the leaves had fallen, over rows of Peas, which partridges and other birds seemed resolved should not get above the ground. If that does not stop them, must place narrow bands of netting over them. Singular enough, the kinds molested are fine Marrows; as yet the birds have let Frames and Dickson's Favourite alone, so, perhaps, there may be as much difference in the foliage as in the Peas. When staked, and a few bushy twigs stuck along the bottom on each side of the rows, the birds generally let them alone until they are fit for the table. Gave a good watering with manure water to Cauliflowers under hand-lights, and gave them an earthing-up. Watered those also planted out in the open air. Pricked-out Cauliflowers and Lettuces that were scattered on the surface of an early Carrot-bed under glass. Sowed more *Kidney Beans*. Looked over those bearing frequently, so that no pod should become too old, as that would be double waste; the pods being useless, and one such pod exhausting the plant more than four or half a dozen when in a nice young state. Syringed in the afternoon with clear soot water, to keep all trace of the thrips, &c., at a distance, this water being as much disliked by the vermin as it is relished by the plants. Removed Potatoes in pots under a little protection, turning them carefully out of the pots, and setting the balls in leaf mould, as a number will yet be produced, and the first bed will soon be fit for use. Hoed and raked Asparagus and *Sea-kale* beds, and threw a dusting of salt over them. As the latter is now coming strong, put two or three dozen of pots over a part, and a piece of turf over the hole in the top, and a little earth round the bottom to keep out light, and a few armfuls of dry litter over the pots; for if a sharp frost come, and the pots be exposed entirely, and the *Sea-kale* 4 inches high, and close to the sides of the pot, it would be much injured, although it would take no harm if fully exposed.

Planted out the remainder of winter Onions. We never do much with them when we leave them where sown in September, they always bulb better for the transplanting. Also, did the same with small sets of Shallots and Garlic, though in most grounds we prefer autumn planting, though they do well with us even after this time. Cleared off a quarter of Cabbage stalks, and laid out the grounds into beds 4 feet wide, with ridges between, and put several inches of half-rotten leaves in the trenches for want of better, which will come in ultimately for Celery, and in a few days will be used in the meantime for turning out great numbers of bedding plants. Pricked out Celery into pots and boxes, and sowed for succession in a mild heat. Planted out a second lot of Cucumbers. Removed the litter and earth from *Globe Artichokes*, and after removing some sucker-roots for a fresh row, will dung and fork the ground round them. This winter we expect none will be injured by the frost; but, nevertheless, we range ourselves among the protectors. We do not make much of a job of it, however; merely place some long litter round the plants somewhat tightly, and then throw some spadefuls of earth from between the rows on, and among the litter to keep it from blowing about, and then fork over the surface of the ground. If the frost should prove very intense, a barrowload or two of litter thrown over the ground will prevent the ground being much frozen. The mere forking of the ground lessens the danger from damping. Sowed in shallow drills the main crop of Parsley out of doors; also, Chervil and several kinds of herbs—as Borage, Burnet, Caraway, and some others sowed in boxes under protection, as Thyme, as the ground was rather rough for such small seeds. Sowed also in rows, 2 feet apart, a good piece of *Sea-kale* and Asparagus on a north border for want of a better. In such a place the *Sea-kale* will be strong in two years, and the Asparagus will be transplanted. Threw charred-heap-and-ashes-material over Radishes, Turnips, &c.,

and fresh planted Cabbages. Sowed a few Broccoli, Savoys, Scotch Cabbaging-kale, Brussels Sprouts, &c., to come in early, deferring the main sowing for a fortnight or three weeks to come. Gave mature waterings to Broccoli plants coming on strongly and well, there having been no frost to hurt them but what could be easily guarded against. Was obliged to remove lots of Lettuces and Endive from earth pits, as their room was wanted for bedding plants.

FRUIT GARDEN.

Here routine attention to watering, air-giving, and firing, and moving *Strawberry plants* and getting others in have been the principal work. The front of the Peach-house being cleared of early Peas in pots, which were transferred to the orchard-house, a shelf has been elevated all the way on pots; and saucers being deficient, and, besides, requiring careful management, the shelf has been covered neatly with an inch of moss, with about half an inch of riddled leaf mould and old mushroom dung on the top of the moss, and all well watered with strong, hot lime water to settle any small snails, &c., that might be in such materials, and on the top of this covering the Strawberry pots after being cleaned were placed. We have long found such a plan in places where a little drip after watering is no object, preferable to using saucers. The moss retains moisture a long time, and yet if the drainage is nearly right, there is no danger of water-logging the plant. The fine weather has made Strawberries really worth eating. As our late vinery gets cleared of plants, we shall introduce many Strawberries in the same manner, and orchard-houses too will get their share.

ORNAMENTAL DEPARTMENT.

For stove plants and Orchids, see the excellent directions of our old friend Mr. Keane. All terrestrial Orchids and stove plants in general that now require shifting will be greatly improved by bottom heat. In fact, where this can be applied, much less atmospheric heat will be necessary. This bottom heat, where it can be given, is a grand promoter of sturdy growth both in-doors and out of doors. Many tropical plants will do well out of doors in summer if only extra heat and manure can be placed beneath them. Occasionally we meet with fine specimens thus managed, but most of us find fermenting material so scarce that we can spare little or none for such purposes. In cold places, even Cucumbers and Vegetable Marrows out of doors in summer do much better if they are planted on a mound of fermenting material. Many fine-leaved plants from the tropics and more temperate latitudes south of ours would do well if holes a yard in diameter were dug out, from 2½ to 3 feet deep, filled more than half with hot dung well worked and then good earth put in, 6 inches higher than the surface, to allow for sinking. Even such hardy plants as *Brugmansias* will produce magnificent flowers and foliage from this treatment.

Cut down and repotted the flowering Begonias. Now is a good time to put in cuttings of *Clerodendrons* for next season; also cuttings of Begonia fuchsoides for blooming in winter and spring. Small plants a foot or so high should also be repotted and encouraged to grow on for a similar purpose. Large plants with masses of drooping flowers look very graceful. Care should now be taken that *Ixoras* and plants of that tribe should not have too much bottom heat, and be watched for any appearance of fly and thrips. Such plants should have a fair amount of air in these sunny days, and be syringed and shut up early in the afternoons, as sun heat is more healthy at all times than fire heat. Ferns must have plenty of shade. Potted more fine-leaved Begonias and *Gloxinias*, and placed them beneath the shade of the Vines. Repotted large *Fuchsias*. Sowed lots of tender annuals also under the shade of Vines, and will remove them as soon as they are up, so that they may have more light.

Pricked-off *Lobelias* and plants of that kind. Just now I wish every pair of hands could be multiplied threefold, as we are rather behind with some kinds of work. Few know before they try it what it is to fill large flower-gardens in the present fashion, and have little or nothing but your plant-houses to depend on as means. The great aim should be to put all bedding plants out before they become drawn or enervated. We inadvertently kept some *Bijou Geraniums* too long last season, and, but for their foliage, they took until September to recover themselves. Removed *Pelargoniums* from second vinery as it was getting too hot for them. These are at present in the cool vinery, and will soon go to the conservatory. That cool vinery—though with fruit until March and filled every inch with plants above and below, and with air on night and day,

except in frost—is now beginning to move, though the place over the Vines is shaded. We are thinning this house as quickly as we can by taking young *Geranium plants* that were standing thickly as they were struck in boxes and planting them out in earth pits, to be protected temporarily. We like to turn them out in compost consisting chiefly of leaf mould, but we are too deficient of that material to do so. Success greatly depends on shallow planting. For this purpose, the ground being rather firm, the surface soil is forked over from 2 to 3 inches deep, allowed to dry, and rough raked. Then a board is obtained, the size of the width of the pit, for standing on, and a shallow trench about 2½ inches deep taken out, a little rough fresh stuff of leaf mould hot, burnt charred heap and fresh loam, is thrown upon it, and the plants are placed along, some 3 or 4 inches apart, according to their size. A little more of this fresh rough material is thrown along and then fastened round the roots of each plant. The plants are then watered with warm water and the surface dry soil is then put over them, patted down slightly with the spade, and the next trench taken out 4 or 5 inches from the first, according to the size of the young plants. In sunny days these plants will have the foliage damped from the syringe, and anything worthy of the name of watering will not be given until a short time before bed-filling time. The chief object is to plant and keep the roots near the surface; for if they go down, when lifted they will flag considerably in the beds. From thus never potting we save a great amount of labour, and chiefly in watering. The earth pits filled with *Calceolarias* are syringed also in the middle of these sunny days, and they are doing nicely. In a brick pit, with glass over them and a few warmish leaves below, we have planted out temporarily *Amplexicaulis Calceolaria*, as that is more tender than most; and also lots of *Ageratum*, which we want strong for rows. Cuttings of that also must be put in. Planted lots of cuttings of the *Cineraria maritima*, in a strong heat. The cuttings slipped off from the base averaged 1½ inch in length, and these tiny bits will make better edgings in May than old plants or cuttings made last autumn. We shall plant out lots of *Verbenas* directly in temporary beds, and put in a fresh batch of cuttings of some of the more distinct colours.

Our readers may recollect of our filling a couple of two-light frames with *Calceolaria* cuttings, having a little heat below them. We do not believe one will miss, but we are put out so that very few are yet rooted and we want the frames for other purposes; and we suppose we must wait a week or ten days more, when a few branches will shelter them sufficiently. No one looking on them cursorily could detect any reason why they are not already rooted. All seem nice and firm at the top; but, on closer investigation, we find that the bottom of the cuttings is somewhat "hung"—that is, the earth and sand had not been pressed close enough to them, except at the surface, and that will make a week or ten days' difference in the time of rooting. We thought of this when our worthy coadjutor, Mr. Beaton, described Mrs. Bird's plan of dropping the cuttings into the holes. In such case there must be plenty of sand, more than we could spare, to wash down by the sides of the cutting, or part of the base may swing in a vacuum, as we find many of these of our spring-put-in ones do. This just shows the importance of minutiae. We do hope that our friend Mr. Beaton will soon be able to be among us, as few, like him, possess the power, with a mere sweep of the pen, of establishing a new idea or perpetuating a useful practice.—R. F.

TRADE CATALOGUES RECEIVED.

J. Salter, Versailles Nursery, Hammersmith Gate, London.—*Descriptive Catalogue of Chrysanthemums, Dahlias, Pæonies, Phloxes, Hardy Variegated Plants, &c. Spring, 1863.*

Bruce & Co., Hamilton, Canada West.—*Descriptive Catalogue of Flower, Kitchen Garden, and Farm Seeds, Bulbs, &c. 1863.*

TO CORRESPONDENTS.

CINERARIA SEEDLING (*H. A. C.*).—The *Cineraria* is of no value, and not unusual in colour. *Cinerarias* are not injured by tobacco fumigation if practised with the usual care. All the flowers you mention may be benefited by weak liquid manure of fowls' dung. One peck to thirty gallons of water would be enough, and not applied oftener than once a-week, nor until after the flower-buds appear.

MAKING A FEERNERY (*G. E. R.*).—Apply to Messrs. Veitch & Son, King's Road, Chelsea. They could send you a man to construct it. You do not say where you live, and we are not clairvoyant.

FLUES (Querist).—We do not know Mr. Ayres' address. He has long left the place you name, and the work mentioned is extinct.

INSECTS ON PLANTS IN VINERY (P. C. D.).—We discovered no insects on the leaf sent, but we saw marks that left no doubt on our minds that you have the thrips. The best remedy you can employ at present is smoking, and that repeatedly, as you cannot wash with the Vines in bloom. The next best—nay, the first best—is to take a small brush and a dish of soap water and go over the leaves of the Vines, and every little jumping or sleeping thrips you see daub him up with the soft moist brush. You would soon thus go over the house, and several catchings would clear the whole. If this is too tedious you must smoke several times, and then, when the fruit is fairly set, you may wash with clear Gishurst, at the strength of about one ounce to two gallons, dissolved the day before, and then gently poured off so as to have the liquor pure and without grounds. This you must repeat often. If you have a boy with a quick pair of eyes, the brush moistened with soap-water will be the best and most effectual remedy. Now, one word as to bedding plants in a vinery. They will do no harm when the Vines are at rest. Your house must now average 65°, and that will ruin the most of bedding plants. We were lately accused as the cause of Calceolarias being a living mass of all sorts of insects, from saying they might be kept in such houses; but no one who has read "Doings of the Last Week" but must have seen that all such plants must be removed before the temperature is much raised. Of all bedding plants Geraniums will stand most heat, especially if they have plenty of light. Without that light all the extra growth from extra heat will be more than neutralised, from their inability to bear the brims of the open air afterwards. Through excess of work, some variegated Geraniums were left too long in a vinery last spring, but they never got over it until September.

LAWN WITH MOSS AND SPIRY HARD GRASS (A Subscriber).—A mossy lawn ought to be harrowed or scratched over with a rake in spring, and slightly dressed with some fine good soil, which might be sifted, perhaps, to remove all stones, and a quantity of grass seeds mixed in the soil, it might then be spread over the lawn and rolled in. A little wood-ashes or lime is also useful to kill the moss. The hard wiry Grass is, however, more difficult to manage; but this generally succumbs to continued cutting, the finer Grasses enduring that ideal better. Most likely, however, the hard wiry Grass is on the poor land, and it may be treated the same way as that which is mossy. Lawns affected with worm casts are more difficult to manage. Watering with lime-water will keep them down for a short time only, but it is a tedious and expensive mode. Thus some take the trouble to take up their turf and put an inch or two of cinder ashes or lime-siftings underneath it. The richest grounds are most infested with worms. Weak gas-water will drive them away, but they return again if the weather be mild.

COLOURS OF BEDDING CALCEOLARIAS AND VERBENAS (A Tyro).—The Calceolarias you mention are *Kentish Hero*, orange buff; *Viscissima*, yellow; and *Sultan*, crimson. The Verbenas are *Prince of Wales*, crimson, yellow eye; *André*, purple; *St. Margaret*, light crimson; *Mrs. Cayley*, white, purple eye; and *Parfum Madeline*, white, violet eye.

QUANTITY OF COCOA-NUT FIBRE DUST REQUIRED AS A MANURE (C. S.).—“A rod (imperial), pole, or perch, or 30.25 square yards, will require one bag or three bushels of cocoa-nut fibre dust. The dust must not be scattered broadcast, but in the rows immediately over the sets; for its properties are not so stimulating as guano or farmyard manure, evidently not being so surcharged with ammonia (nitrogen); but it (the dust), yields nitrogen by the process of decomposition as in the case of all decaying vegetable substances, slowly but surely. Its advantage over manure seems to be due to that continual yield of nutrition being as abundant when the plant is developing as when it is sprouting; whereas in manure it is richer when the plant least needs nourishment.—G. A.”

GRUBS IN FLOWER-POTS (A. T.).—The grubs sent to us were the larvae either of *Elbio Marci* or *Dilophus febrilis*, two-winged heavy-flying insects of a shining black or red colour. We have generally considered the grubs feed on decaying vegetable matter; but they will doubtless also feed on the fine rootlets of plants, which should be repotted into earth which has been baked.—W.

FLOWER-GARDEN PLANS (M. C. E.).—We have no doubt that No. 1 will look very well, but we prefer No. 2, and we would not mix the edgings at all as you propose; but on all except the four narrow beds at the ends we would have a broad edging of 12 or 15 inches round each bed, and these should be all pretty level throughout, centre and edgings. Then suppose you edged 3 and 4 with blue Lobelia, we would edge 1 and 2 with variegated Alyssum. Then we would cross the others—as 5, 8, Ageratum, with borders of Tropaeolum, yellow, well diseased; 6, 7, yellow Calceolarias, band of Purple King Verbenas, and edging of Cerastium if liked. Then cross 10, 11, and 9, 12, bordering all instead of mixing, and try this for the present year. The borders must be close up, joined to the centre, but kept in a straight line from it.

BULBS IN POTS (H. B.).—To make the most of bulbs done flowering, they should be kept at first under glass, and watered well so long as the leaves remain green, then placed in a sunny place and kept dry to ripen.

CAMELLIAS AND AZALEAS AFTER FLOWERING.—(Idem).—The Camellias and Azaleas may be kept close in the greenhouse, or removed to more heat, where they will form their wood and set their buds earlier.

SOWING CLIANTHUS DAMPIERI (Idem).—The seeds of *Clianthus* must not remain long in the hot water—say ten hours. We prefer doing so before sowing, and 130°, 140° or so instead of 100°, as when you steep earth and altogether, it is apt to make a quagmire of the soil.

CUCUMBERS DISEASED (A Constant Reader, Littlehampton).—We think it is likely they have taken “the disease,” but, perhaps, it is only a burning from deficient ventilation. Stir the surface of the soil, throw a slight sprinkling of soot on the surface, and if the back of your frame or pit is very white, dull it with a mixture of soot and sulphur made into a paint. Leave also a little air on all night.

INDIAN SEEDS (T. B., Leeds).—They rarely are worth trying to cultivate. The Cape Gooseberry is *Physalis edulis*. The Marvel of Peru is *Mirabilis jalapa*, and is described in the Dictionary. The other species, perhaps, is *Mirabilis suaveolens*. The Giant Convolvulus may be *Convolvulus maximus*, a native of Ceylon. The other names are too indefinite to be identified.

ORCHARD-HOUSES (Inquirer).—The Harlow Station is the nearest to the Sawbridgeworth Na series, and we know that Mr. Rivers will admit you, or any one, to see his orchard-houses.

BURNING CLAY (Starkie Baldwin).—The clay will certainly be turned into a hard, red, lumpy substance like bricks; but we have always found that it was easily broken up into a brickdust material, which is just what is required to mix with and disintegrate a heavy soil.

MANURES (An Amateur, Surbiton).—How can we advise you without knowing the plants you are cultivating?

CLIMBER FOR GREENHOUSE WALL (J. B.).—The *Cobaea scandens* would grow very quick, but it is slightly herbaceous, though it would always be green. Perhaps as a mere cover or shade, *Cissampelos* or any other greenhouse *Cissus* would be best, as it runs closely and always presents a thickset of green.

SOWING DEODAR SEEDS (Sophia).—Split the Deodar cones and beat them a little and the seeds will drop out, or you may take them out. Sow in loam, slightly covered, and put in a cool place under glass.

COVERS OF OUR VOLUMES (Idem).—There is no difficulty in obtaining the covers through any bookseller. Their price is 1s. each.

FLOWER-GARDEN PLAN (Idem).—The colours are pretty well arranged. Such lists as you require have been often given. The other week you would see the planting of a flower-garden at Straffan—all low things. As your beds are only 3 feet across, we would prefer planting each bed of a colour. We think all these will do, except those to which we allude. The beauty of the picture will consist in having the plants about the same height. We therefore think *Perilla* will be tall for anything you have, unless you stamp it down well. For the same purpose the *Linum* will be too tall for a crimson, and the *Clarkia* would be more suitable. A crimson *Verbena* would be better still, and more lasting. For whites as in unison with *Saponarias*, you might use white *Clarkia* or white *Feverfew* pegged down; but the best would be white *Verbenas* or white *Alyssum*. For violet we fear the *Convolvulus* will be too rampant, and we would prefer such things as *Verbena Purple King* or *Charwoodii*, and for lilac such a *Verbena* as *pulchella*. At this season, however, we can only criticise the intended planting of our friends—we really cannot plant for them. The scarlet and yellow *Nasturtiums* must be well picked of leaves, or they will be too strong for the rest. We dislike the most brilliant colours being in the centre of such a group, and therefore your *Nemophila discoidalis* will do. We think you would improve your figure by having the central circle white, and as you have twelve clumps round it in six pairs, you could put a scarlet pair for violet. In the four clumps at the two corners you might put white where white is, and *vireo-vera*. The other week a list of annuals was given for a small garden.

PRIMULAS, &c. (Tyro).—Division of the plants and offsets are the modes of propagating Primulas; cuttings cannot be made of them. Tobacco paper can be bought at wholesale tobacconists, but shag tobacco we prefer for fumigating.

NAMES OF FRUIT (H. Pedley, Tenterden).—The Apple is evidently a seedling, and appears to be a good kitchen sort. The naming of it will rest with yourself. Being a good keeping Apple, it deserves to be cultivated.

NAMES OF PLANTS (E. A. S.).—It is useless to attempt naming Ferns in the seedling state, as are all those you have sent. They will alter entirely by the time they get matured. (*J. S.*)—*Dipsacus sylvestris*, or Wild Teasel. (*C. B., Knaresborough*).—It is *Daphne mezereum*, a native of England. (*F. N.*)—*Fabiana imbricata*. (*C. F.*)—*Omphalodes verna*. (*M. H. R.*)—1, *Platycodon alceiformis*; 2, *Adiantum formosum*; 3, *Adiantum cuneatum*; 4, *Selaginella uncinata*. (*M. B., Yorkshire*).—1, *Oncidium carthagenense*; 2, *O. luridum*; 3, *O. altissimum*, apparently; 4, *Dendrobium Pterid.*

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE POULTRY CLUB.

ALL associations of men for the purpose of assisting each other in harmless and useful pursuits deserve the support of their fellows, provided the grounds on which they start are sound. When, however, the object they have in view is unattainable, or appears so to some, it is the duty of these to make their notions public.

“Members to be expelled the Club at a general meeting.” What is to be the effect of expulsion? The Club is not like the Jockey Club—it has no competing ground which is its own property, or where it is paramount, and can prevent the peccant party from exhibiting.

“Committees of Poultry Exhibitions to be requested to place their Shows under the rules of the Club. The Stewards to appoint Judges when desired to do so. The Judges to judge according to the rules drawn up for their guidance.”

If the Club means to do anything at all, it ought to provide Committee, Secretary, and Judges. It should offer pen money. It might advertise that any place having a fitting building, and undertaking to provide the sum of £ —, shall, on application to the Poultry Club, be provided with a poultry show, conducted on the most approved principles. There is no objection to the appointment of Judges, but there will be difficulty about the rules. Who shall judge the Judges? Fancy a Yorkshireman at the Spangled Hamburg class, and finding in his book of rules that Golden cocks must have black breasts. He would resign—a black breast is a heresy in his eye. In the search after immaculate Judges, it will occur, perhaps, that for English Shows it may be desirable to have Judges from Scotland or Ireland. Both pin their faith to purely black breasts and tails in Dorkings. Fancy the dismay in the general class.

But the “Judge or Judges,” what are they to do? They

must judge according to the rules; and any person having a complaint of a glaring departure from the rules of judging, shall lay the same before the Stewards who may be present to investigate. The Stewards to call on the Judges for an explanation. This rule appears to be a joke. Has it entered into the minds of the framers to ask themselves whether the office is a profitable one, and whether men of standing and position in society are disposed to submit to this? Any one would suppose, and it may be so, that there are competent persons who are constantly applying for the office, and either that it affords them a livelihood, or that the office has such charms that those who seek to fill it will submit to such rules as these.

But let us deal with the programme. "A want has been felt of a fixed standard by which each variety may be judged." The list of Stewards comprises some of the most successful exhibitors in England. If there has been such difficulty in knowing how to breed for certain points of excellence essential to success, whence arises their good fortune, for it can be nothing else?

The duration of poultry shows, and their success where they are well conducted, bear good testimony to the soundness of the awards taken as a whole, while the position constantly occupied by certain yards proves that good strains hold their own.

We like clubs; contact is good and profitable for men engaged in the same pursuit. The communication of knowledge one to another; the record of novel and interesting events connected with the pursuit; compiling statistics, of which we stand so much in need; and the treatment of the poultry question as one affording a delightful and healthful amusement—all these come within the legitimate scope of a Poultry Club, and are calculated to do good; but when the Committee of Stewards talk of laying down rules for judging, we think they have only to try them among themselves with closed doors to find the impossibility of agreeing.

We believe the Club's outset to be in the wrong direction, and we anticipate a short life for it.

MALAY FOWLS.

In your Number for March 10th (which, unfortunately, I did not receive until the end of the week), I notice a letter from Mr. Fox, of Devizes, asking for a fixed standard of points to be adhered to in rearing "Malays," and referring to the variations in opinion amongst judges respecting the points of this breed. You have appended a very full, and, in the main, a very correct description of those points; but as a Malay breeder and admirer of twenty-five years standing, I am desirous of pointing out what appears to me likely to be misunderstood in your description. I refer to the use of the word "scanty," as applied to the plumage. If your meaning be that the feathers should be very short, I quite agree with you; but this is not the meaning generally attached to that word. Were it possible to number the feathers on the body of a fowl, I believe it would be found that every breed possesses the same, the difference being length and softness in some breeds, shortness and hardness in others. Amongst the latter I place the Malay. I know of no breed in which the feathers are so short and hard; but I demur to the necessity on this account, for the plumage to appear so scanty that any part of the body should exhibit a destitution of feathers. Certainly, "the plumage should not hide shape," which it would do if long, loose, and flowing; but unless the plumage be in the most perfect order, and brilliant in metallic lustre, the shape of the body and shortness of feather render this breed the most ungainly of any; and it is owing to the absence of condition in plumage, in which so many owners of Malays exhibit their birds, which gives rise to the remarks we often hear at exhibitions, in depreciation of this most valuable and (if shown as they ought to be) majestic breed. Your description ends with the sentence, "there is no fixed colour for the legs or plumage." As to plumage, of course all colours are admissible, from white to black; but the legs, in every case, should be yellow. Birds with legs of any other colour could not be exhibited in the Malay class.

I fear in many cases perfection of plumage has been lost sight by some of our judges, and prizes awarded to birds of good blood, though in wretched feather. I venture to think (and upon this principle I have ever myself acted in awarding prizes, whatever might have been the breed) that blood and feather should both be looked for in greater or less perfection; but that birds

possessing only one of these qualifications are ineligible for securing a high position on the prize list.—CHAS. BALLANCE.

[We have seen as good Malays with white legs as we ever saw with yellow; and we have seen birds in the highest condition running in a farmyard, faultless in lustre and feather, yet showing the points we noticed in our last—viz., naked parts of the body and wings.]

TAUNTON POULTRY ASSOCIATION.

I AM sorry to find that this well-managed and promising Show is dissolved. I cannot perceive what the non-attendance of the subscribers has to do with it in any way. So long as they pay their subscriptions it is quite optional whether they attend the meetings of the Association. The resignation of the Secretary is, I grant, a serious obstacle; still, is there not some enterprising gentleman on the Committee who is qualified "and at the same time willing" to undertake the laborious duties of the Secretary? I do hope Mr. Ballance will reconsider the matter, and, if he is still determined to give up the office he has held "so ably for some time," he will find a substitute.

I have sent several pens to this Show for the last two years, though the distance is over three hundred miles each way, and the birds always returned to me in excellent feather and condition, which speaks well for the general management; and the plate and prize-money were always sent to the successful competitors within a week after the closing of the Show. Mr. Ballance I always found most obliging, doing everything which lay in his power to please, and, at the same time, win the confidence of his exhibitors.

I am convinced many exhibitors have no conception of the downright hard work which devolves on a secretary in a show of say four to five hundred pens, and am the more confirmed in this opinion when I see the thoughtless remarks which are occasionally made, "that the Secretary and Committee have no right to be exhibitors." What absurdity! Why, who would do the drudgery if these unselfish individuals had not the chance of a prize? And I dare venture to say nine out of ten of the Committeemen throughout the country keep prize poultry.—WESTMORELAND.

WORCESTER AND BATH AND WEST OF ENGLAND POULTRY SHOWS.

THE POULTRY CLUB.

My attention has been directed to a letter in your columns relative to the length of time the birds have to be kept in the yard at the Worcester Show, and I say that I altogether agree in the opinion expressed by the writer. The arrangements of the approaching Bath and West of England Show appear, however, to be still more objectionable—the birds in that instance being required to be in the yard by ten on Friday morning, whilst the Show will not open till the Monday morning following. Surely the parties who have superintended these arrangements must either have had but little experience in the duties they have undertaken, or have committed a serious oversight; for unless the circumstances are of a very peculiar character indeed there can be no necessity for having the birds cooped-up so long before the Exhibition commences. Besides, as any one with the least pretension to experience in such matters well knows, few birds can undergo such an ordeal of confinement as that involved in the five days during which the Show is to be open, and the three-days confinement previously, especially at such a season of the year, without serious injury—an injury that would render them next to valueless as exhibition birds in future. It is, indeed, a question whether the chickens would survive it, the heat of June being, in fact, far more trying for birds thus penned than the cold season of December. Then the old birds will be on the point of moulting, when they are unequal to sustaining the same amount of hardship as at other times.

Before closing this communication, I will, with your permission, add a remark or two on the Poultry Club in the course of formation. I had quite expected to see the matter more fully canvassed in your paper.* It is right that those who are interested in the subject should be put in full possession of the objects contemplated in its establishment, and the mode in

* The writer had not seen what we published last week.—EDS. J. OF H.

which it is proposed to carry them out. Discussion on these points could not fail to be beneficial. What I have been able to gather from your paper, and from a friend or two who were at the private meeting of the Poultry Club, has by no means favourably impressed me.

If I am correctly informed, it is intended to frame a series of rules by which birds are to be judged—a course of procedure which could not fail to bring the Club into collision with those who have to perform the duty of judges. What gentleman of any standing as a poultry judge, would, if he had any self-respect, submit to the kind of dictation implied in placing in his hands a code of rules drawn up by parties less conversant with the subject than himself? Besides, there are points in connection with the merits of different birds for which no rules can provide, and any one who is not capable of judging poultry without the aid of printed rules, has no claims which qualify him to fill the office, and ought not to aspire to it. It would be interesting to hear the opinion of some of our best judges on the subject. If, as I also believe is the case, it is the intention of the Club to appoint the judges at some of the principal shows, I should like to know how Mr. Hewitt would feel on the matter, if his appointment should be accompanied by a number of rules to direct him in the exercise of his office. It is very problematical whether he would accept it under such conditions.

That there is great room for improvement in poultry exhibitions is undeniable; but it is questionable, not simply whether such an arrangement would work advantageously in promoting that object, but whether it would be practicable. Whatever improvement is to be effected, it is certain it must be by the mutual concurrence of both judges and exhibitors, without which the most promising arrangements would fall through.—J.

EXOTIC HONEY BEES—SIZE OF THEIR CELLS.

I AM indebted to the kindness of Mr. Charles Darwin, for specimens of bees and comb of two foreign kinds of honey bees, which differ in many respects from either of our European species. The first is a bit of virgin comb and bees sent by Mr. Mann, either from Fernando Po or the opposite mainland of west Africa. The bees, as far as I can identify them, are *Apis Adansonii*, and are much smaller than their European brethren, but with this exception appear nearly identical with the *Ligurians*, possessing the same orange-coloured abdominal rings. Their comb, on the other hand, differs in no respect from that of the common hive bee, if we except a reddish tinge, due, probably, to the colour of the honey which it once contained, and from which it had originally been secreted. Although, as before stated, the bees themselves are notably smaller, their cells are of precisely the same diameter as those constructed by the European species. Secondly, I have a piece of brood-comb and bees of the species *Apis testacea*, brought by Mr. Wallace from the island of Timor, in the Eastern Archipelago. Those bees and the allied species, *Apis dorsata*, are about one-third longer and stronger than our English honey-bee, and are indigenous to Borneo, Ceylon, Hindostan, and the islands of the Eastern Archipelago. Their extraordinary size is evidenced by the sealed brood-comb, which is no less than an inch and one-third in thickness, whilst sealed brood-comb of *Apis mellifica*, at any rate during the first year, is barely an inch thick. The great area of their wings, and the length of their abdomen, appear to me conclusive as to their wonderful powers of flight, and great honey-gathering capabilities; but I was amazed to find that the most careful measurement resulted in establishing the fact, that their cells likewise were of precisely the same diameter as those of the European species.—A DEVONSHIRE BEE-KEEPER.

WOODBURY FRAME-HIVES MADE IN STRAW.

THE advantages possessed by straw over wood as a material for the construction of bee-hives have often been pressed upon my attention by apiarists whose great experience entitles their opinions to the utmost respect, whilst the course of events in my own apiary has been such as often to give weight to their suggestions. One obstacle, however, has always stood in the way of my adopting straw hives, and this has been the difficulty of procuring them of the perfectly square form required for the

reception of frames. When last in London I drew the attention of my friends, Messrs. Neighbour & Son,* to the advantages possessed by straw, and suggested that they should endeavour to produce a straw hive which would meet my requirements. I have now much pleasure in announcing that they have perfectly succeeded, and manufacture Woodbury-hives in straw, equalling wood in firmness, squareness, and stability, and which, in fact, leave nothing to be desired; whilst their moderate price is an advantage by no means to be despised. I have already many of these hives in use in my own apiary, and I think few will regret following in this respect the example of—
A DEVONSHIRE BEE-KEEPER.

* 149, Regent Street, and 127, High Holborn.

EVENTS OF THE SEASON.

THERE was a nest of young Thrushes, nearly fledged, in Leadenhall Market last Tuesday.

SILVER PHEASANTS began laying March 17.

THE first Plover's eggs were sent up to London March 24th. The usual day is on the 25th. In 1862, the first came in on the 21st.

OUR LETTER BOX.

DIARY OF THE DAIRY, &c. (*A Gardener*).—Its publication has been abandoned, we believe.

CRÈVE CŒUR HENS DYING (*M. J.*).—The symptom, "swelling of the abdomen until it touches the ground, becoming red and death ensuing," intimates that the egg-passages are inflamed, probably from the birds being overloaded with fat. Give them a table-spoonful of castor oil, no hard corn, very little barley or other meal; but plenty of boiled potatoes and lettuce-leaves.

MANAGEMENT OF CALIFORNIAN QUAILS (*Constant Reader*).—There is little difficulty in keeping and breeding the Californian Quail. They require only a small space. Their food is simple—oats, barley, and green meat. They are very prolific, laying from twenty to thirty eggs, a few of which they may be allowed to rear themselves. A very successful breeder who keeps many pairs, has them in different divisions round a yard; one pair in each cage or pen, which is about 6 feet in depth by 3 wide. Each pair in turn has the run of the whole yard or enclosure, which is more than half greensward. This, it is said, prevents the hens from getting too fat, which is dangerous for them in the laying season, and often fatal. There is really no art in keeping them; all they require is gravel, dry dust, oats, barley, and green food, with as good a run as may be convenient.

CHICKENS WITH COLDS (*P. W. T.*).—If the chickens which snuffle and have mucus in their nostrils roost on the stones of the stable, they are suffering from chill contracted from it. They must not roost on board, brick, or stone. If they have taken to the stable they will not be satisfied elsewhere. Make up a warm corner for them, and cover it so deep with dry gravel or sand they shall not feel the damp through it. The best treatment for the snuffle, is to feed three times per day with stale bread soaked in ale. You may give, if that fails, small pieces of camphor half the size of a pea.

MALAY FOWLS' LEGS (*F. J. C.*).—We do not at all agree with you about the legs of Malays, and we repeat our opinion that the colour is not essential.

BREEDING CANARIES (*R. C. B.*).—Keep the birds together a little longer—say a fortnight—and give them egg, mawseed, and hemp, and provide them, if not already done, with building materials. Do not take out the slide, the pans will be better separated. If at the end of the fortnight the birds do not agree, we would advise you to change them; but we think that they will be sociable after a time.

REAL SPRING CHICKENS (*A Subscriber*).—The fowls that produce the "real spring chickens" are to be had in Sussex only, about Handcross, Cuckfield, the neighbourhood of Lewes, and East Grinstead. The *Brahma* *Pootra* is the fowl you want, as they will rear themselves in any weather.

PREVENTING HENS SITTING (*H. N. D., Woolwich*).—There is always more or less of cruelty in preventing hens from sitting, as it is a natural operation. The most humane plan is to shut them up in a bare place, where there is neither hay, straw, box, basket, nor hole. They will look for something or somewhere to sit upon, and, failing it, at the end of a fortnight may be turned out with the others.

COCK DROOPING (*A. H.*).—We fear some internal organ is chronically diseased. Give a dessert-spoonful of castor oil, and offer him some bread soaked in ale.

KEEPING FOWLS (*R. Godfrey*).—Your space will do for a cock and three hens of Buff Cochins-Chinas. The place under the stairs would do for a roosting-place, if enclosed. The wire-netting had better be 5 or 6 feet high and no rail along the top. Have some limy rubbish in a corner, and the floor of the roosting-place covered with 3 inches deep of sand.

LONDON MARKETS.—MARCH 30.

POULTRY.

There is but a small supply of poultry at market; but the trade is so bad, there is as much as is required.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 55.7° and 35.3° respectively. The greatest heat, 79°, occurred on the 7th, in 1859; and the lowest cold, 20°, on the 10th, in 1850. During the period 130 days were fine, and on 122 rain fell.

HARDINESS OF SIKKIM RHODODENDRONS.

R. ROBSON, at page 224, has referred to my having found two or three species of Sikkim Rhododendrons hardy. It may interest him, and perhaps others, to know that I have found all

that I have had to do with, consisting of those sent over by Dr. Hooker and distributed from Kew, perfectly hardy, with the exception of Dalhousianum and Edgworthii.

They have now been planted out in the open borders for five years, and many of them have flowered; but, unfortunately, like all the first cross with the Nepaul varieties, they flower too early to be of much use out of doors, unless in very favourable seasons.

At the time I am writing (March 30), I have ciliatum in beautiful flower; also a plant of Wallichii 5 feet high, with a fine truss expanded, and others swelling fast. This is pretty much in the way of the old campanulatum, only the colour is deeper. Robustum is another in the same way, but with larger leaves and more compact habit. Thomsoni and fulgens both look very promising, but have not flowered out of doors yet. Campylocarpum has flowered the last three years. This has a compact truss, individual flowers rather small, and the colour is a delicate violet purple. Glaucum, which is figured in the same Number, flowers very freely, and when in flower is very pretty, but the plant is not always handsome. Cinnabarinum and anthopogon have also flowered freely. Madden's argenteum is a very compact-growing plant, and when larger will have a very handsome appearance without flowers. But the gem of all for foliage is Falconeri, and it is as hardy as a laurel; but unfortunately the leaves are so large and heavy, that unless very much sheltered they get broken by high winds. Barbatum, also, has a very good foliage, and is a handsome-growing plant.

Some others which with me came up amongst the fulgens, but are very different from it, are very promising in foliage and habit, but have not yet flowered. The great fault of most of them is early flowering, and early starting into growth, by which the points of the leaves are sometimes nipped by the morning frosts, giving them in the summer the appearance of being burnt; yet, notwithstanding all drawbacks, they are an interesting race of plants, and likely to find work for the hybridiser for some years yet.

I have not had much experience with the Bhotan varieties; but I have one plant now, said to be a Bhotan,

No. 106.—VOL. IV., NEW SERIES.

which has three beautiful, yellow-looking, smooth flower-buds, with no sign of expansion yet. If it turn out well I will let you know.—JOHN COX, *Redleaf*.

FUMIGATING WITH TOBACCO.

GARDENING operations of many kinds call for a display of tact as well as of skill. In fact, those two qualities are closely allied, and to a certain extent are, or should be, inseparable. What the skilful man does he does well, but tact enables him to do it quickly, and often with imperfect means. Thus he economises time and material while doing everything at the right time and in the right place. Much has been said about taking time by the forelock and having everything done in advance, so that one may be prepared for a season of pressure; but this is only one side of the question, and the man of tact has no occasion to hurry at any particular season, although he does not, to ordinary observation, keep in advance of his work.

In no particular is a display of tact more requisite than in doing battle with the various pests which to the careless gardener are a source of trouble and anxiety, but which the man who possesses tact takes as a matter of course, for he knows how, when, and where to meet them. The appearance of green fly, thrips, scale, mealy bug, red spider, &c., on his plants, if they do appear, gives him no anxiety, for he applies the remedy or remedies, and it is done with; but then comes the question, What are the remedies? A dozen gardeners will answer the question in as many different ways.

In my school-boy days I remember almost every boy in the school had a way of his own of forming the figure 8. One would commence below on the right hand, another on the left; one would begin at the top, another would make a regular pothook of it, and some, again, would make a horizontal dash to connect the points, and so on. In this way gardeners differ in performing some of the most simple operations for destroying green fly. One says, Use nothing but the best tobacco, and apply it by means of the bellows; another says, Use the flower-pot pierced with holes. One says tobacco paper is best; another, Try Neal's pastils; and consequently Neal's pastils are tried, probably with not sufficient strength, and the fly is not killed, or the dose is too strong, and the plants are killed as well as the fly. Advice of this kind is often given and taken; mishaps occur through misunderstanding or misapplying the remedies, which are set down as ineffectual, and are, with those who recommend them and the vendors, mentally consigned to the rubbish-heap, if a more unpleasant situation does not happen to be before the mental vision of the disappointed experimentalist.

In the process of fumigating with tobacco or tobacco paper—for, in my opinion, both are equally safe and effective—I could never perceive the necessity of being in the smoke myself, or of seeing others inside the house with it, for apart from the fact of the operator being

No. 758.—VOL. XXIX., OLD SERIES.

almost suffocated, the door has to be opened as, half choked, he leaves probably before the work is complete. There is another objection: the smoke hangs about a person's dress, while the smell does not improve by age, and lasts for several days. To be inside the house during the operation is by no means necessary, as I have always found: consequently, I never use the ordinary fumigating-bellows and dislike them, although some are so firmly attached to them as to prefer them to every other appliance for fumigating.

Now, the various ways and means of fumigating which have come under my own immediate observation convince me that more depends upon the way in which the smoke is applied, and on adapting the quantity to the space to be fumigated, than on the material itself. I have used the different sorts of tobacco and also tobacco paper, and find that nothing better could be wished; yet one is no better than the other. I once wished to try the pastils, but at the nursery where I applied for them they said they had not any at the time, and that their experience of them was that they destroyed everything but the insects. How true this was I had no opportunity of proving. I have heard from those who have tried them that they are unsafe; but, as I never take the bare word of others in such matters, having known several instances of plants being killed or injured, as was alleged, with bad tobacco or tobacco paper, but in reality, as I am pretty certain, through the quantity being disproportioned to the space, I can, therefore, say nothing in their favour or otherwise. With regard to tobacco and tobacco paper, I have used both in several different ways; and if I have found the leaves of plants marked or the insects not killed, I blame myself, and not the material, for that is entirely blameless.

In the first place, it is always best—at least, I have found it so—to fumigate towards night, when the house is shut up and there is no fear of the sun shining on it, and then, as it has been often recommended, it is better to smoke two nights in succession than to depend on one fumigation, especially when it is for thrips, because it takes a strong dose to kill these all at once, and the quantity of smoke necessary to do so may injure the plants; but when the insects have had a weaker dose it makes them sick, and before they have recovered, a similar dose the following night settles them.

It is, then, worth while to take the measure of the enclosed space, and find out, if possible, just the exact quantity of tobacco or paper that will give the required quantity of smoke. This is advisable, both on the score of economy and to save time and trouble in doing the work effectually. There is more tobacco wasted through doing the work ineffectually than many would believe. I have been surprised myself when told that 7 or 8 lbs. of tobacco had been used, or rather misused, for smoking two small houses within three weeks, and this in cases where the operators were supposed to understand the matter. I have found half a pound of tobacco, or the same weight of paper, quite sufficient for a house 30 feet long by 16 wide and 9 feet in height; and this made into two fumigations, with, perhaps, a trifle the most at the last performance. A pit or frame will require much less, for it must be remembered that the height makes a great difference in the quantity of material requisite; for the farther the plants are from the roof the denser the smoke should be. In a pit the plants are generally within a few inches of the glass, and it is in such structures that plants are generally injured from an over-strong application of smoke. It is, therefore, advisable to use but a very small quantity of tobacco in smoking pits and frames, and to increase the quantity if the dose is found ineffectual.

In applying the smoke, the plan I generally prefer is to take a common flower-pot—a 32 size is very convenient—place it on a larger one that stands on the ground inverted, so that the apertures of both are clear for the draught of air. Put in the upper one a few pieces of charcoal ignited, and when they are thoroughly alight tear up some brown paper and put in, and then put on the tobacco or tobacco paper, which will consume gradually and give out a good smoke. Another plan I have generally adopted with regard to small houses, frames, &c., is to take some coarse brown paper, steep it in a solution of saltpetre, dry it, then spread out the tobacco on pieces of 6 inches or a foot square, roll both together, and tie with twine or matting. Then suspend by one end and light the other; let two or three of these be lighted according to the size of the house or pit, and let them smoulder. If properly done, this will be found as clean and effectual a method of fumigating as need be.

F. CHITTY.

RHODODENDRON CULTURE.

In your article on the above subject in your Number for the 24th ult., I was surprised to find it mentioned that the Sikkim *Rhododendron ciliatum* did not succeed well out of doors. With us, about 550 feet above the level of the sea, it, with several others of its class, grows and blooms far better outside than in pots in the conservatory. I may instance *Falcooneri*, *fulgens*, *Thomsoni*, *Hookeri*, besides the three arboreums, *scarlet*, *rose*, and *white*, *Russellianum*, &c., as sorts that have been out here for from five to eight years, and are growing luxuriantly, but have not all flowered as yet. One, *ciliatum*, has been out thirteen years, and is now covered with bloom, being about 2½ feet high and more than 3 feet in diameter; I enclose a flower and a leaf of it; the latter is, I think, double the size I have ever seen the foliage of it on house plants.

With respect to hybridising generally I do not entirely agree with Mr. Robson. I have found the best results from avoiding too much similarity between the parent plants; for instance, in crossing two *Fuchsias*—say *Clio* and *Queen of Hanover*, the progeny, from seventy to eighty plants, were wretched, with leaves like *microphylla*, and worthless flowers; while in crossing a dark and light variety the progeny were often good, while some took after the one parent and some after the other.

Recollecting that the original *Fuchsias gracilis*, *globosa*, &c., which now grow 7 feet high outside, were once considered greenhouse plants, I planted-out several of the improved varieties about six years since, which I find do nearly as well as the common sorts. For instance: *Venus di Medici* in the open ground is about 3 feet high now and as much in diameter. Some are still killed to the ground in a hard winter, but come up again strong before the 1st of April, and are beautiful objects in the flower garden.—H. H. GLENVILLE.

SENSATION NAMES.

PRAY give a little wholesome advice to some of your contributors and advertisers with regard to the naming of novelties, &c. Our nervous system had scarcely recovered itself from the weekly attacks of the "Roaring Lion Strawberry" when we were as much astonished, as we had been terrified before, by the announcement of the "Good-Gracious Polyanthus." Some of your readers, if we recollect rightly, were rather shocked at the last-named epithet; but we are free to confess we were not morally sensitive on the point, but merely regarded the name as simply ridiculous. We have, however, been slightly startled by the sudden appearance in your No. 104 of the "Phantom Bouquet," the subject of which is a review of a book of that name on the art of skeletonising leaves, &c. The author has, probably, taken a leaf out of Mr. Home's book, or accompanied that spirited individual in an aerial exploit, hovering occasionally over garden rubbish-heaps, and holding communion with departed vegetation. How this may be we know not, but this we know, that it would be well to check the prevailing taste for such absurdities; and if you would be instrumental in doing this you would confer a favour on the majority of your readers, and especially—R. T. E., *Shrewsbury*.

THE WARDEN OF WINCHESTER'S GARDEN.

THE readers of THE JOURNAL OF HORTICULTURE are no strangers to this garden, or at any rate to its gardener, for Mr. Weaver has oftentimes given them the benefit of his lengthened experience and ripened judgment; and as I heard much of him from a valued friend and earnest horticulturist, I determined on a late visit to the old cathedral city of William of Wykeham to pay him a visit. And although March is but a poor month for seeing gardens, even though after a mild winter, I was, as I was assured I should be, most pleased with all I saw and heard; and perhaps a few reminiscences may not be uninteresting to your readers.

When I speak of the Warden's garden, it should be borne in mind that we are not talking of one with acres of glass, miles of hot-water pipes, and with a mint of money at command to meet all the requirements of a first-rate place. The motto of the Wardens seems to be *utile et dulce*—a little more of the former than the latter. The place is not a show place, but an ordinary quiet but pretty garden, having the charm of a fine lawn and a nice stream of water; giving one, perhaps the notion

that the Wardens, fresh from the remembrances of classic Oxford, had tried their best to reproduce in their own way the scenes of cloistered ease which make the daughter of the Isis so perfectly unique and charming. Nor, again, is Mr. Weaver one of the new race of what some one has called "kid-glove gardeners." He has not the ologies all at his fingers' ends, although cases of British and foreign insects and books, presented to him by the students of the Training College in gratitude for his instruction, attest that he is a lover of nature and able to use his mother tongue. No: Mr. Weaver is one of those shrewd, honest, hardheaded men, who are accustomed to listen to what everybody has to say, but to have a judgment of their own and act upon it—no blind adherent of old customs, but no extravagant praiser of new-fangled notions, and therefore one finds in his garden a good combination of both old and new methods and plans.

I saw him first in his fruit-room. Bless me! what a quantity we hear about fruit-rooms, and trays, and shelves, and all sorts of things as necessary to keep Apples and Pears, until one begins to be thankful that we do not grow enough of them to need such an elaborate structure. But what was Mr. Weaver's fruit-room? Simply a shed—such as we ordinarily term a potting-shed, with the simple addition of a door to be locked and kept all secure. "But, then, of course, it was all arranged with shelves and straw, &c." Nothing of the sort—a few common boxes, in which the Apples lay some foot in depth, touching one another (an awful notion, I believe, in the fruit-room); and yet out of these he took Ribston Pippins, Sykehouse Russet, Court of Wick, and Scarlet Nonpareil as fresh, bright-coloured, and crisp as the day they were gathered off the trees; and he told me that he has more than once had his Apples frozen hard without any apparent detriment; though when the winter is very severe he removes his boxes into an inner room, the roof of which is thatched very thickly and quite frostproof.

As I am speaking of fruit, I should mention that in a little garden attached to his own house he has an orchard-house, in which he grows some fine Grapes and has planted a few Peach trees; but, like most practical men, he has a contempt for fruit trees in pots. He says that where one has a clever man, whom it pays to give a large income to, and where expense is of no consequence, there it may be done; but that even then the fruit is poor in comparison with that grown on trees planted out. I have never myself seen an orchard-house but what the owner had to make many apologies for failures (always excepting Mr. Rivers, of Sawbridgeworth).

In another small house heated by a flue he had also some Vines, from which, he said, he had always fine crops. Formerly the walls of this garden were completely covered with Black Hamburg Vines, which were, when in fruit, quite a picture. About four years ago mildew attacked them, and he has been obliged since then to give them up.

But to return to the Warden's garden. There is there just that combination of the old and new styles of gardening which one longs to see. There is a noble herbaceous border which runs round the lawn, and in it a fine collection of the best and most showy plants of that class so planted as to allow space for large plants of Pelargoniums, &c., to be placed out amongst them in summer; while in another part there is a small parterre laid out for bedding things. Thus flowers are secured at all seasons, and that "ploughed-field character" which one's own garden assumes at this season is obviated.

In the vegetable and hardy fruit garden everything betokened the superintendence of an active and sensible man. I learned there a few things hitherto unknown to me. Mr. Weaver, for instance, never ridges up his Asparagus-beds, as he says digging between the beds is sure to cut up some of the roots, which in old beds (and some of his are said to be 100 years old), are sure to make their way across. He manures well, and gently forks the beds over. Neither will he tolerate an Asparagus-knife, nor allow the shoots to be cut deep beneath the soil, as he says injury is sure to be done to the stools by it, and that he does not see the advantage of having a long white stalk with a little edible piece at the top. It appears that the late Warden was a great lover of the Asparagus, and that hence it has been cultivated with zeal, and I may say with great success. Mr. Weaver has before this given his experience on its growth in the pages of THE COTTAGE GARDENER, and I can well believe that the beds are very fine.

Then as to Strawberries. What think our fragarian friends of growing only yearling plants, and planting them close to-

gether—say about 9 inches from plant to plant, and in quincunx style? Yet this was Mr. Weaver's plan; and on my expressing a doubt as to the quantity produced he assured me that the crop was very large. His plan is to keep the hoe gently at work amongst them; and at this period to give them a good top-dressing, which helps them on wonderfully, and he says you can have no idea of the crops that he grows.

Raspberries, too, were never allowed to be dug between. There were beds there twenty years old that never have had a spade amongst them. The hoe is liberally used and manure freely given. Of these, again, the crops are said to be very fine, and from the appearance of the canes I can well believe it.

I do not at all dislike either to see new plans or to try them; but when there is such a rage for "novelty," it is really refreshing to find one who dares to keep to old plans; and without being *laudator temporis acti*, or believing "no times like the old times"—not moved from what he knows to be good plans by all the alleged charms of new beauties—it seemed of a piece with the old grey ways of the College, for one felt that to have found everything "spic span and new" would have been incongruous. I quite enjoyed my little chat; and in many pleasing recollections of the old cathedral city, do not esteem that to be the least when I had an opportunity, even in March, of visiting the Warden's garden and making the acquaintance of Mr. Weaver.—D., Deal.

THE PROFIT FROM FARMING TWO ACRES.

I MADE the acquisition the other day at your office in Fleet Street, of a small work, "How to Farm Two Acres Profitably," by Mr. Robson. The book is an excellent one, so far as it goes; but, notwithstanding its great merit, I was disappointed at not finding one word regarding either expense or profit, the alpha and omega of any enterprise whatever.

Now, I look upon you as a sort of godfather to the little book in question. Allow me to inquire, What sum may be necessary to bring the two imaginary acres into the state supposed by Mr. Robson? and what profit may be reasonably expected from the same at the year's end?

My intention is to farm ten acres profitably, both for pleasure and emolument; and having the outlay and income for two acres, it requires no great stretch of arithmetic to multiply these by five to obtain the result for ten; though not quite, as ten may be more economically worked than only two.

For Mr. Robson's guidance, I ought to state that I may come into possession of the ten acres unprovided with even a spade, and as practically ignorant of agriculture as a Hottentot, though as learned theoretically as an Alderman Mechi: consequently, I must have an intelligent and practical man to assist, and often to advise, in carrying on the various operations of the field, which is to be reckoned on the side of expenditure. I mean to have everything done on the most recent scientific principles, but without launching out into experimental speculations. The desired site to be within a marketable distance of London, if possible, or that of Torquay, or other eligible place on the south coast.

To resume: What is the outlay and income of the two acres? supposing I come into them as unprovided as father Adam into his farm. The same as regards the ten acres? the land being purchased in both suppositions.—W. B.

[Upon handing the above to Mr. Robson, he writes us as follows:—

"I confess it is far from being an easy matter to give such a reply to the letter of 'W. B.,' as he would like to have. True, it is easy enough to put forth a set of figures that might appear feasible, and could even be supported by the absolute practical working of such things; but I have deemed it better not to do so, as local circumstances have so much influence on the *pro* and *con.* of such undertakings, that statements such as might be given in a tabular form in one case, would only mislead in another.

"The original intention of the little work referred to was to give advice to any one not acquainted with rural affairs, who might be disposed to retire to such a place in a suburban or country district, much, if not all of the produce being supposed to be wanted for the consumption of the family of the occupier. This, however, would not be the case in the ten-acre holding; so that the ordinary rule of multiplication cannot be applied there.

"Ten acres may be managed very prudently, and I may say

profitably, by having eight acres of it grass land, if the owner wanted to keep a horse and a cow or two, and the remaining two acres as described, while it is hardly likely that he will want all the ten acres in garden stuff; and if he cultivate for sale, he ought well to study what the ground is best adapted for, and plant more extensively of those crops for which it is suitable. Even then, unless he has well studied the requirements of the market in his neighbourhood, he will find it difficult to undersell those whose personal and practical experience is already in the field against him; but he may succeed, though, probably, not until after some practice. This need not surprise 'W. B.,' who if he be a city man retiring to the country, with a view to make gardening pursuits as profitable as he may perhaps have made his city business, it is not unfair to ask if he could write a small work on the mode of making a fortune by the business he has just left, and make that work intelligible and easily to be followed by a midland county's farmer with a certainty of success.

"It is easy to perceive that a close attention to the minutiae of business in both cases will alone be accompanied by a good result; but the pursuit taken up early in life is the one most likely to prosper. However, I would not dishearten 'W. B.,' nor any other person intending entering business of this kind; but I will help him a little in calculating his labour expenses. His returns I must leave him to estimate himself; only it is fair to say, that if he require all the produce of two acres for his own use, it ought to be calculated as worth the retail price he would have to pay for it if he bought the articles at the greengrocer's.

"Trenching on dry, stony ground is worth £6 per acre, and 9d. per load for the stones taken out. In many cases these stones are sold to a good profit to the road surveyor and others. If there be tree roots on the ground, a pile of these stacked up close together, making 128 cubic feet, is often sold for 8s. or 10s. This, when dry, often sells for double that amount. Special agreements for work of this kind are sometimes entered into, allowing the workman to have either the roots and stones, or both.

"Digging is done in various modes. Rough digging, shallow, and the turned-up portion not broken, is from 16s. to 18s., or 20s. per acre. This is often paid for what is dug up in fruit plantations. Deeper digging and breaking the clods is worth double this amount. A hedge may be trimmed in summer for 1s. or 1s. 6d. per 100 yards. Mowing of hay, if the crop is good, and in the neighbourhood of a town, will cost 6s. or more per acre. Mowing short grass is difficult to calculate, so much depends on the way it is done. In fact, it is not easy to say what ought to be given for any piece of work without seeing it; neither is it fair to enter into calculation of the profit and loss of undertakings without being on the spot when the undertaking is in working. Railway prospectuses have put forth plausible tables which experience has over and over again proved were hollow and worse than useless. I can, therefore, only say to 'W. B.,' that by using great prudence, economy, and perseverance, he may make his ten-acre cultivation a paying undertaking.—J. ROBSON."

This is just the answer we expected. Soils, situations, and seasons so vary that no one can give a prophetic table of profit and loss with any reasonable prospect of approaching the real result. The best guide for "W. B.," will be the man whose services he purposes retaining, and who, if intelligent and trustworthy as well as industrious, will be the surest leader to success.]

RHODODENDRON SEEDLINGS AND CULTURE.

I AM glad to see in your Number for the 24th ult. a reply to "J. N. M." on the subject of "Rhododendron culture." May I say a few words on the subject? Having grown thousands of seedlings from the best hybrids, I asked one of the questions, which your correspondent there puts, of Mr. Standish, and he very kindly replied to me that "all the best Rhododendrons generally come true from seed." Of course there is a chance of obtaining varieties where the plants are grown in juxtaposition.

It may interest "J. N. M." to know that Rhododendrons *barbatum*, Thomsoni, and Campbelli (all Sikkim), have proved perfectly hardy, and the foliage good at all seasons. These have been planted out since 1858 in an exposed northerly aspect here. Rhododendron *ciliatum* was cut down to the ground in 1861, but is now covered with flowers, having been potted last autumn, and placed in a cold pit on frosty nights or days. All the Bhotan kinds

proved too tender. *Azalea indica alba* has been out in the same exposed portion since 1856, and has flowered every year, remaining unhurt, though unprotected, when Laurels and Bays were all killed or severely injured by frost. Having now proved these plants hardy, they are to be moved into a more sheltered position, to give the Rhododendrons a chance of flowering, and to allow the *Azalea* to flower where the north wind will not tear the blossoms. This is, you may be assured, a rather cool spot, rather damp, and feeling early frosts more than most places in Ireland. Were I to name the county it would mislead your readers, as at one side of the mountains the Myrtle blows as well as in its native *Ischia*, while on this side the climate is more like Switzerland without the advantage of its milder latitude.

I see in your Number of November 25th, 1862, a reply to "AN OLD SUBSCRIBER" (I am an old one, too), in which it is said that "manure is not only not good, but an actual poison to *Azaleas*, *Rhododendrons*, and *Heaths*." This must, no doubt, be true under certain conditions, or it would not be so distinctly stated; but the old saying holds good here, "What does not poison fattens," for in every case in which I have used old well-rotted manure the results have been most satisfactory. Manure, containing long straw or other undecomposed material of that kind which would render the soil open or loose, is certainly most injurious, either applied to the ground before planting or dug-in afterwards; but, indeed, digging is, I think, always destructive to all the *Ericaceae*, and if ever the earth is to be stirred it should be done with a fork, and never even then except to apply manure.

Perhaps you will consider it of sufficient interest to allow me to give your readers the following advice given by Mr. Veitch in his catalogue for 1861, now before me. He says, "Bog or peaty mould is the best; but when this cannot be procured good fertile loam with a dressing of rather fresh cowdung once in two years will grow them well;" and he adds, "a good mixture for them [*American plants*] can be made as follows:—To three parts half-rotted leaves add one part of the turfy surface of a meadow cut about 4 inches thick; to this add a good quantity of white or other sand. Chop but do not beat the soil, and use as rough as possible; should the foliage become yellowish topdress with cowdung, or the use of liquid manure about four times during the month of July will soon change them to dark green." Mr. J. Waterer recommends "well-rotted stable-manure in proportion of one barrowful to six of the former ingredients."

I should not trouble you with these remarks, but that I have saved the lives of some of my most valuable Rhododendrons by the application of manure. Here and there, too, I find a Rhododendron *ferrugineum* losing almost every leaf, but quite revived by pointing-in well-rotted manure, after opening a trench outside the ball of roots, and filling it up with the same stuff. Curious enough, Rhododendron *hirsutum* grows better here than *ferrugineum*. These two kinds, by-the-by, I have never met with in their wild state growing together; they generally occupy distinct districts, though growing at the same altitudes.

In conclusion, it is worth while to remark that though much of the soil here is that best fitted for Rhododendrons, yet there are two other soils in this place—viz., fine limestone gravel and fine rabbit sand of decomposed granite. On both of these last there are to be seen good healthy Rhododendrons, of course more dwarf and less luxuriant, the soil being, I believe, almost entirely devoid of vegetable matter, and no mixture of manure or any thing else being applied; and it may be worth while remarking that on these soils the Rhododendron *ponicum* strain does better than the *catawbiense*.

Enclosed is a small paper of Rhododendron seed of fifty of the best hardy named kinds, having flowered together last season. This is for your correspondent "J. N. M." should he wish for them.—D. C. M., Ireland.

IMPORTANCE OF GENERAL KNOWLEDGE.

IN a late article on attention, &c., which has met with more consideration and sympathy than I ever expected from the greatest gardeners and the employers of gardeners, I borrowed a sentence or two from a nobleman when addressing an Institute at Birmingham. I have just read with great delight the address of the noble Premier on his installation as Rector of the University of Glasgow. I would urge the reading of that address, and that of the Duke of Argyll and others, upon my younger brethren;

and for the sake of those who may not see it entire, the following extract from the speech of Lord Palmerston is well worthy of a place in THE JOURNAL OF HORTICULTURE, where it is sure to come before great numbers of young professionals.—R. F.

"You are all of you, probably, destined to some one particular profession, make everything that belongs to that profession the object of your intense and preferent study; but do not on that account omit acquiring general information on other matters whenever opportunities may present themselves to you for doing so. Whatever the profession a man may enter into he will perform the duties of that profession better by having general knowledge, and that generality of knowledge will not interfere with the successful study of the particular line which he determines to enter. Do not be discouraged by people who say, It is absurd to have a smattering of different things; 'a little knowledge is a dangerous thing.' A little knowledge is better than no knowledge at all. Learn a little of everything of which you can learn anything, it will be useful to you hereafter; though it may not be in your own line, it will be the foundation on which you build up as you go along through life. But bear one thing in mind—be not content with regard to many things with mere rudimentary information, but what little you know, know it well. Do not accept a jingle of words for reality of things: go to fundamental principles; know accurately that which you are desirous of knowing, and, however little that may be, depend upon it that upon that basis you will be more able to build up the future superstructure," &c.

BOILERS.

THE mere fact that there are so many kinds of boilers made and advertised proves that few meet with general approval, and also that there must be a great difference in opinion as to what is required. The only idea which appears to be patent to all boiler-makers is to present as large a heating surface to the action of the fire as possible, and this, all will allow, is a most important one.

I will give my idea of what is requisite to make a perfect boiler, and if those who have had still more experience will do the same some information will be the result.

The points I should insist upon are—1st, That the boiler be made of cast-iron, having proved that wrought-iron ones soon rust through; 2ndly, That it should present as large a surface as possible to the action of the fire; 3rdly, That the return-pipe enter the lowest part of the boiler, and in entering shall not pass through any brickwork whatever; 4thly, That the inside of the boiler be easily examined and cleaned; 5thly, That the furnace be calculated to burn any kind of fuel; 6thly, That there should be room for a good body of fuel under the boiler.

With regard to the third point, in my opinion a most important one, I have seen only one boiler—that of Mr. McNab, of Edinburgh—which in this respect appears to be made on a correct principle. If a boiler be surrounded by a mass of brickwork, and the return-pipe pass through it, it must happen that the circulation will be impeded as the bricks become heated. The bottom of the return-pipe being much hotter than the water returning to the boiler a return current is set up, and the general circulation interfered with. I have lately seen a boiler pulled down that from this cause would not work at all, but the return-pipe in this case passed through a great thickness of hot brickwork.

There are so many boilers made the inside of which cannot be got at, that my fourth point must be generally considered quite unimportant, and perhaps, if nothing but clean soft water is ever used it is not absolutely necessary; but who can be quite sure no one will ever use hard water with or without his consent? There are many boilers only calculated to burn coke or the best large coal; a boiler of this description must be an intolerable nuisance to a man who can procure good cobbles at half the price of coal, or whose cook will not burn up the slack. With regard to the last point, it will be found much more economical to have a good body of hot fuel if the draughts are under control than to be always poking the fire and mending it up, besides requiring less attention at night.

I feel convinced when gardeners have settled what are the requisites of a perfect boiler one will be made much better than any now in use.—J. R. PEARSON, *Chilwell*.

MESSRS. A. HENDERSON & CO.'S HYACINTH SHOW.

THIS month, as usual, the Lapageria-house at the Pine Apple Place Nursery is gay with a choice assortment of Hyacinths and other early flowers; and though, owing to the past year having been unfavourable to the bulbs, some of the spikes are scarcely equal to those shown in previous seasons, the display is well worth inspection.

The stage in the centre of the house is filled up in the middle with young *Araucarias excelsa* and *Cunninghami*, two nice plants of *Araucaria Bidwilli* being placed one at each end; and round the centre of green foliage thus formed, and which serves to set off the flowers to advantage, the Hyacinths are ranged in three rows. The whole of the pots are mossed over, and surrounding the whole is an edging of *Isolepis gracilis*. The side stages are likewise filled with Hyacinths and early Tulips, and from the roof are suspended six baskets filled with Hyacinths edged with *Isolepis gracilis* and having Ivy wreathed round the outside. Near the entrance is a very large basket of Hyacinths in bands of white, blue, and red, arranged on a conical eminence and surrounded by Golden Fleece *Geranium* and *Isolepis*, the whole producing a striking effect. The opposite end of the house is occupied by a bank of *Eparis*, among which *Viscountess Hill* is a pretty crimson variety.

Of the Hyacinths the following are some of the best:—*Single Whites*.—Lord Gray, a very fine waxy white; Madame Van der Hoop; Mont Blanc; Richardson, waxy blush, very fine; and *Tubiflora*.

Single Red.—Beranger, deep red; Charlotte Marianne, striped; Diebitz Sabalskanski; Herstelde Vreede, bright pink, fine; Lina; Mrs. Beecher Stowe; and Solfaterre, brilliant orange scarlet.

Single Blue.—Bleu Mourant, Charles Dickens, Couronne de Celle, Emicus, Grand Lilas, Grande Vidette, Keizer Ferdinand, Orondates, Prince of Saxe Weimer, Robinson (nemophila blue, tinged with lilac on inside, very pretty), and William the First.

Double Red.—Bouquet Royal; Comtesse de la Coste, dark rose; Duke of Wellington, and Panorama.

Double White.—Anna Maria; La Tour d'Auvergne; and Triumph Blandina, blush, with pink eye.

Double Blue.—Mignonne de Dryfhout, pale blue; Paarlboot; Pasquin; Sir John Franklin, marbled blue; and Van Speyk.

Blacks.—General Havelock; La Nuit; Mimosa; Prince Albert; and Uncle Tom, a good dark purple.

Of new sorts, Bouquet Constant, deep red with paler edges; Baron Rothschild, crimson; Jenny Lind, pale rose with pink stripe; Princess Charlotte, rosy pink; are all good single varieties; whilst Petronella Cornellia is a pretty double blush with pink stripes, and Passe Mabopolasser a very fine single violet blue.

Among the Tulips Golden Standard had the leaves edged with white; and of the others, Grand Duc, Keizerskroon, Vermilion, Brilliant, and Thomas Moore, were the most striking.

Several fine varieties of Narcissus were likewise shown, of which Luna is a splendid double white and orange with very large flowers; Malakoff, a fine pure yellow; and Amiable Bouquet, a very large white with yellow cup.

SHADING FERNERIES—FLUE-HEATING.

IN "G. A.'s" article in your Number of the 17th inst. I can see something useful as well as ornamental; but I think some shading may be found more under control than paint on glass. Still, as "G. A." states it is for a permanency, I cannot find so much fault. I, however, wish to point out one or two drawbacks to its general use.

Firstly, Paint, labour, &c., could not well be done carefully under 6d. per square yard. Secondly, Its being put on a little too thickly will occasion great expense of money and time to replace it with a thinner coat. Thirdly, In winter the more light obtained the better; but the paint is still on, and cannot be removed without being washed with soda and water, costing as much to take it off as it cost to put it on. Fourthly, Paint when put on in that style is apt to flake within a year when exposed to a very hot sun and much rain, owing to the want of union with the glass.

Now, what we require is something with which to wash glass with the least expenditure, and producing greater benefit, and with less evils to contend against—something, for example, as may be readily removed when required, so as to be used not only for ferneries, but also stoves, greenhouses, and pits, and I will now offer my opinion as to what this should be.

If we place a small quantity of unslacked lime in a quart of milk, we shall find a substitute for paint on glass: it will give a beautiful shading, which can easily be put on more thickly, or done away with on the first wet day, or on being syringed and

then gently rubbed with a common house-broom. The labour is small, the cost is next to nothing; no tradesman has to be employed, but merely a boy may be trusted to apply it carefully.

"G. A." is right in daubing it on with a dust-brush; for if done in the regular way, unless performed by a very light hand, it will leave many streaks, through which the sun will have sufficient power to burn the green leaves beneath.

Next, this question presents itself to our notice: Should it be applied outside or inside? If the latter, it will last much longer, excepting where there is very much moisture, but will not allow you to obtain any heat from the sun; on the other hand, if applied outwardly, it will give a nice shading, and allow a quantity of heat to be obtained from the sun during the summer months.

Great care ought to be taken in putting it on, so as to avoid covering the paint on the wood, as it is liable to make the paint perish sooner than it otherwise would do. I have seen this simple composition used for the last eight years, and never found any fault with it, and I shall continue to use it. I have tried a mixture of soot and milk for the same purpose, but find I cannot put it on thinly enough to allow of the admission of sufficient light.

One may kill two birds with one stone, if possible. I will, therefore, call your attention to "E.'s" article, which almost immediately follows that of "G. A." Flues, with one or two exceptions, may be considered a dead loss, as compared with hot-water pipes. I would never have the one if it were possible to have the other, as flues are always out of repair, let the smoke out, cause nasty smells, take up much room, and are accompanied by a dozen other annoyances.

In regard to heating by hot air, that might do for a manufactory or warehouse, where you wish to keep articles dry, but never for a greenhouse or stove. Only fancy a quantity of hot, dry air coming against some young foliage: I think it would inevitably burn it. I fancy we always require a certain quantity of moisture in the houses, which would be done away with by "E.'s" plan, unless he stood by all the time to syringe his earthenware pipe. Let him go to Mr. Monro, nurseryman, Colney Street, near St. Albans, and see his excellent manner of heating by hot water. His trials have at length brought him a reward in the shape of a new-fashioned boiler, which quite astonished me when I saw it work. Mr. Monro would be most willing, I believe, to put up a boiler for any one who would, if the boiler succeeded, buy his discovery and have it patented. I am not in a position myself, or would most willingly, for I am certain it only requires to be seen to be brought into general use. He has one at work, which he made himself, and it heats two houses, and is expected to heat a third, with merely rain-water pipes.—J. E. L., JUN.

ROYAL HORTICULTURAL SOCIETY.

MARCH 31.

FLORAL COMMITTEE.—A Meeting of the Committee was held this day on the right-hand terrace of the conservatory at South Kensington. Although there were not many subjects sent for examination there were several plants of much interest and beauty, and which would have amply repaid any of the Fellows for a visit to the garden on that day.

Messrs. Smith, of Dulwich, sent a *Verbena* named *conspicua*, a deep rosy crimson with clear white eye. Also *Azalea Surprise*, flowers of a pinkish ground; the centre of the petals blotched and spotted, and sometimes striped with bright red—a very showy variety with badly-formed flowers, though considered useful for decorative purposes. Messrs. Smith sent also a seedling *Azalea Oracle*—a pretty, smooth, rosy-tinted flower, after the style of *Standard of Perfection*, which it much resembled.

A seedling Wallflower came from F. J. Graham, Esq., and was much admired for its brilliancy of colour—a bright yellow. The scent of this single-flowering variety was most exquisite, and a label of commendation was awarded, it being considered an advance upon other Wallflowers in cultivation.

Mr. Jackson, of Kingston, sent an early-flowering *Pelargonium*, Mrs. Lewis Lloyd, with bright showy carmine flowers; the upper petals deeply marked with a dark spot; the throat purple. Although not possessing the usual requisite properties, a label of commendation was awarded, being a decided improvement in the early-flowering class of *Pelargoniums*.

Mr. Earley, of Digswell, sent cut specimens of three varieties

of *Intermediate Stocks*. Mr. F. Hopwood, a *Cineraria* named *British Sailor*, with a light blue disk, but not equal to many named varieties.

Mr. Bull, Chelsea, sent five *Zonale Pelargoniums* of various shades of colour, also a variegated-leaved variety. No award was made to them at the present season. When they are seen again in the autumn some of these seedlings cannot pass unnoticed. *Auricula* and *Beauty* appeared promising varieties. Mr. Bull also sent *Petunia Captivation*, a very showy single variety, with mauve flowers margined with white; semidouble *Azalea Duc de Nassau*, not new; *Cupressus Lawsoniana variegata*; an *Amaryllis Fire King*, a bright scarlet variety mottled with white, flowers small but very conspicuous. A label of commendation was awarded.

O. Anderson-Henry, Esq., sent a curious plant—*Phædranassa obtusa*, which had no particular merit. The plant had lost its foliage, and perhaps did not appear to the best advantage.

Messrs. Veitch, Chelsea, sent several plants of interest. Among them *Dendrobium luteiflorum*, a very handsome Orchid, to which was awarded a first-class certificate. Perhaps the most interesting plant on the table, sent by Messrs. Veitch, was *Anthurium Scherzerianum*. This plant was exhibited by the gardener to the King of Hanover last July, at South Kensington, and attracted much admiration from its extremely novel and handsome appearance. It is nearly allied to the *Arads*, bearing bright scarlet spathes, with beautiful dark green foliage. It reminded one of the scarlet Flamingo, and might well be named *flamingoides*. A first-class certificate was awarded, which it most justly merited. Messrs. Veitch sent also two *Camellias*, Filippo Parlatore and Giardino Santerelli, the former a very beautiful variety, with flowers of a pale pink ground, with finely-formed petals, striped and flaked with deep rose. A first-class certificate was awarded. The latter *Camellia* was not in condition to receive any award; but there could be no doubt about its being a first-class variety.

Mr. Standish, Bagshot, sent *Bletia* sp. from Japan. Although a weakly plant, it promises to be a useful one. The deep purplish-mauve flowers and elegant grassy-looking foliage were much admired, and when stronger plants are exhibited will gain its award. This will probably prove to be a greenhouse Orchid.

Messrs. Henderson, Wellington Road, contributed greatly to the interest of this Meeting, by sending a collection of beautiful plants, among them an *Amaryllis*, with very dark-shaded red flowers, which received a label of commendation. Two red and white varieties of *Primula sinensis filicifolia* received a second-class certificate. We noticed, also, several other *Amaryllids*, *Rhododendron Veitchii*, *Rhododendron Princess Alice*, *Azalea rhododendroides*, *Hymenocallis speciosa*, and many others. A special certificate was awarded by the Committee to this collection of plants.

ROYAL HORTICULTURAL SOCIETY'S READING-ROOM.—This is now open; and we think that no two opinions will be entertained, either as to the comfort and beauty of the room, or the liberal supply of daily and weekly papers upon the table. We think a book should be kept, and an attendant, to ascertain the number of Fellows who avail themselves of this gratuitous luxury.

SEA-KALE.

I HAVE in my garden a bed of *Sea-kale* which, owing to a new treatment, has yielded very abundantly. Last autumn I had the whole bed covered with seaweed about a foot deep. The *Kale* grown under the seaweed is so much finer and more abundant than that grown under pots, that I shall discontinue the use of pots, and thus save great expense. I have had shoots of *Sea-kale* quite tender and white, of from 12 to 15 inches in length, and 1 to 1½ inch in diameter. I have only to watch its appearance above ground, and then to uncover it to the root. Would you recommend a similar treatment for *Asparagus*?—T. W. B.

[So writes a correspondent, and communications like the above are invaluable. Unfortunately, it is only those of our readers who reside near the seacoast that can avail themselves of the seaweed spoken of; but there is no question but it will suit the *Sea-kale* to the very letter. We are not exactly certain, however, about it suiting *Asparagus* so well, although we have no doubt but to a certain extent it will do so. If the soil be light and open the seaweed will be highly useful; if, however,

on the other hand, the ground be stiff and heavy, the effect will not be so good as a quantity of sea sand probably would. We have, however, not had much experience with *Asparagus* so treated. We would rather invite further communications on the subject.]

FUMIGATING WITH TOBACCO.

I HAVE seen no plan more simple and effective than mine. I have an iron bowl with a handle rivetted to it. The bowl is made of good strong sheet iron; the handle is about a foot long. The price of it here is about 6d. I had mine given to me, it being no more than a "waster" before being galvanised. I had about twelve holes punched through around the bottom of it, and I have had it in use about two years, and it looks as good now as it did before it came into use. I think it beats the flower-pot system of burning tobacco, for the pots are so liable to break with the fire that is in them. I put a few bits of wood on the top of the greenhouse fire, and in about ten minutes the wood will be burned down to a glowing heat so as not to cause any smoke from the wood when it is in the house. I damp the tobacco-paper, cut a few laurel leaves with it, put the wood coals into the bowl, turn three small flower-pots upside down, set the bowl on them with the tobacco-paper put on the top of the coals, go out, shut all up close, and in five or ten minutes the house is full of tobacco smoke. There is no necessity for stopping in the house, for the tobacco-paper will burn without any trouble.—W. F., *Wolverhampton*.

ESTABLISHING A ROOKERY—ROOKERY FORSAKEN.

THE means of inducing a number of rooks to colonise any given place is a subject which has already received various answers from some of the many able readers of *THE JOURNAL OF HORTICULTURE*. But, though various suggestions have been given on this point, there are at least two known ways of attaining what in some localities is so great a desideratum; and I give them below, as they have not, I believe, been referred to before in these pages.

If upon any of the trees in or near the place where you would wish to induce the rooks to nest, the nest of either a magpie or a jay can be found, watch (if the former), the nest carefully, until you are sure the old bird has done laying. This being known, procure from some neighbouring rookery five or six eggs which you are confident have not been sitten upon. Having obtained them, watch for a convenient time to climb up to the magpie's nest, and change the eggs when the old birds are absent, which they will be for a long time during the day or two which occurs between the date at which the hen ceases laying and commences sitting. Should the old ones perceive you, proceed in carrying out your object, trusting they may not forsake the nest.

The jay, though quite as good a foster-parent to the young rooks as the magpie, is exceedingly shy of being intruded upon. Should you have in your grounds one of their nests, from the moment you know of its whereabouts studiously leave it to itself until you suppose the old one is sitting, when eggs from some rook's nest should also be procured—but this time, if possible, in an early stage of being set on. Keep them perfectly warm until near the nest, where one should first proceed, disturb the old bird, and, by following it whichever way it went, endeavour to drive it further from the nest. This done, a second individual having the eggs should quickly climb up and deposit them in the room of those already in the nest, leaving as quickly as possible, for of all the birds of which we have had experience none will so readily forsake its nest as the jay. I have known it do so repeatedly where an individual had but once climbed up to it, and this without disturbing it in the least.

Though I here give a suggestion or two, I would trouble some of the many readers of this *Journal* for any further experience they may have in this matter also. We have here this very season lost the rooks which had hitherto been as secure upon the premises as their own new-made nests upon the trees. They have unaccountably left abruptly and entirely, one and all. Can any one inform me of the cause? Some of them had actually commenced their nests this spring, but this was no sooner done than others came and destroyed them. I then acted

upon the suggestion I found in these pages—namely, placing a broom upon the trees. I did more, for I caused to be built-up in one of the very crooks where a nest rested last year an attempt at a fac-simile of a rook's nest. This seems as yet to have been of no avail: no heed have I seen taken of it save once, and this by a rook seemingly larger and darker than the generality of them—a member of their gravest debates possibly; for certainly he seemed to treat this nest with great derision, as was evident by a species of ironical croaking and other strange sounds. Now, as we happen not to have either jays' or magpies' nests here, the thought has occurred to me, Why would not the jackdaws do as well or even better than either, still leaving the broom and man's nest in the branches above?—W. EARLEY, *Digswell*.

P.S.—We have been in the habit of destroying the jackdaws for the last year or two. I think none remained in the rookery this spring. Can this have caused our friends to leave?

CULTURE OF THE GENUS CHOROZEMA.

By PAUL PROGRESS, Esq.

OF all beautiful New Holland plants, the plants belonging to this interesting family are the most beautiful; for, blooming almost throughout the year, and more especially through the winter and early spring months, they contribute to the decorative appearance of the conservatory, or yield a few flowers for the bouquet at a time when they are especially acceptable and valuable. They are also plants of tolerably easy cultivation; at least, those who have learned the rudimentary principles of cultivation will find little difficulty in managing some of the more showy examples of the family. Others, as *C. Henchmanni*, and *angustifolia*, are more difficult to manage; but, before we conclude this article, we will endeavour to make their cultivation clear and easy to all.

The *Chorozemas* are propagated by cuttings of the half-ripened young wood, taken off in July or August, making choice of the short, stiff, and weak, or medium growth, but avoiding twigs of a robust habit. These, after being trimmed, should be about 1 inch long, and must be inserted in sand, under the protection of a bell-glass. In preparing the pot for the cuttings, take care to drain it thoroughly, by filling it half full with potsherds, then place fibrous peat about an inch deep over the drainage, fill up with clean silver sand, and the pot is ready for the cuttings. It is indispensable that a little peat be placed under the sand, as it affords nourishment to the young plants, until they are potted-off, and admits of their being allowed to remain longer in the cutting-pot than would be advisable if they were growing in sand only. After the cuttings are all in, place the pot in a close, cold frame, water when necessary, and wipe the condensed moisture from the inside of the glass twice or thrice a-week. Here the cuttings must remain until they are cicatrised, when they may be removed to a rather warmer situation, the pots be plunged in a very slight bottom heat, and, in a few weeks, they will be ready to pot-off. If it is late in the season—say the end of October, before the cuttings are in a fit state to pot-off, it will be the best plan to let them remain in the cutting-pot through the winter, and to pot them off in February; but if they are fit for single pots in September, then they will be much benefited by being potted-off early.

The plants when sent out from the nurseries are generally from twelve to eighteen months old, and, at that time, should be established in fire-inch pots. Presuming you have selected dwarf, healthy, bushy, well-rooted specimens, prepare the following compost: rich fibrous peat, two parts; leaf mould, one part; turfy rich loam, two parts; clean potsherds and charcoal, broken to the size of horse beans, one part; with sufficient gritty sand to make the whole, when mixed together, light and porous. Time was, and that but a year or two back, when cultivators, to secure porosity, used the soil in rough pieces, and "a down-westward" cultivator, to show the strength of his affection, has recommended pieces the size of a brick. Thus, though this served the purpose of growing the plants rapidly for a short time, they soon became unhealthy, for, the compost being deficient in silicious matter, from the impossibility of mixing the sand with the coarse pieces of turf, it soon became unhealthy, and hence the plants were brought to a premature end, much to the disappointment of the cultivator, whose labours were cut short just at the time when his anticipations were at the highest

pitch. Now, those who understand the mixture of composts pursue an opposite course, and, after selecting their soil, and divesting it of all superfluous and inert matter, they break it into small pieces, so that the whole will pass through the meshes of a half-inch sieve, and secure porosity by the intimate admixture of sand, potsherds, charcoal, or soft porous sandstone broken small. In this way the compost is of the same quality throughout, and hence the roots receive neither check nor change of food; but when large pieces are interspersed through the mass, the roots of the plants either avoid entering them altogether, or by entering them, are subject to constant changes. This is the rock upon which the advocates of "the accumulative," "the one shift," and "the large shift" potting system foundered; they got plants to grow rapidly for a time, but that time was limited, and at the end of it death was the *finale*.

Let us not be misunderstood. In repudiating the rough compost, and the one-shift, we do not disapprove of a large shift, but we would enter our protest at once and for ever against the use of rough compost. Look to Nature: The primæval clod, do we find it like a honeycomb, loose and open like a basket for Orchids? No. But do we not on the contrary, while it is sufficiently permeable for the free ingress of air and water, find that it is firm and compact, and sufficiently solid to prevent the changes of every breeze that blows? In this way progress is comparatively slow, but certain; and the plants, instead of progressing with great rapidity for a time, produce strong, healthy, thoroughly matured wood, and dwarf compact growth, yielding abundance of bloom; and which abide with you for years. But to return to our young plants:—Having prepared your compost examine the roots of the plants, and if they are strong and healthy, prepare a pot two sizes larger, and after draining it properly proceed to pot your plants, placing some of the roughest part of the compost over the drainage, and proceeding to fill up firmly with the finer soil.

The best place for the plants after potting is a close frame or pit, taking care to ventilate freely, but to keep a moist atmosphere, and to shut the frame up for an hour or two every evening, but open it again either partly or wholly before retiring for the night. In this way the plants will make rapid progress, and, therefore, due attention must be paid to stopping the rude shoots so as to induce close, compact, and healthy growth. If the plants progress as they ought to do, they will probably require a second shift during the season, and, indeed, if you wish to make the most of your time, the plants may be kept growing slowly until the winter fairly sets in, at which time they should be brought to a state of rest. In the second year some of the plants will produce a nice head of bloom; but, in order to secure rapid growth, remove the bloom-buds when quite young, and keep the plants vigorously growing through the second season. For potting, no general rule or time can be specified; if a plant is in good health, and the pot full of roots, a shift any time between Christmas and October will not injure it; but never shift a plant until the pot is full of vigorous roots, and take special care that the roots do not become matted before you shift the plants.

Manure water in a weak state may be used with advantage to hardwooded plants of all kinds, but use it with caution, and not more than twice a-week. That prepared from sheep's dung and soot is the best, but it must be used in a perfectly clear state.

Chorozemas are subject to the attacks of red spider, and also to thrips and mildew; the best remedy for the whole of these pests is sulphur and water, vigorously and plentifully supplied. Take a plant and lay it upon its side in the open air, then with a syringe wash it thoroughly, and after watering dust it with sulphur, and repeat the dressing until the pest is destroyed. *C. Henchmanni* and *angustifolia* are the most subject to mildew,

but it may be destroyed by the timely application of sulphur and water.

The following are some of the most distinct and beautiful of the species which are met with in cultivation:—

C. angustifolia.—A remarkably graceful shrub, with long, slender, somewhat scrambling stems, having linear, acute leaves, with recurved margins, and racemes of pretty flowers, of which the standard is orange yellow, and the wings crimson purple. Flowers in March and April. New Holland. Introduced 1830. Formerly called *Dillwynia glycinifolia*.

C. cordata.—An elegant dwarf shrub, with many slender branches, clothed with sessile cordate obtuse, spiny-toothed leaves, and bearing the flowers in more or less drooping racemes. They are orange in the standard, with scarlet or crimson wings, sometimes scarlet with purple. Flowers in March and April. New Holland. Introduced in 1836. There are numerous varieties as regards the colour of the flowers. A fine variety of this species, with a more vigorous habit, and larger and deeper-coloured flowers, is called *C. cordata Lawrenceana*.

C. Dicksoni.—A handsome, dwarf, bushy-growing shrub, furnished with narrow leaves, and bearing a profusion of beautiful dull scarlet and yellow flowers, something in the way of *C. Henchmanni*. Flowers from March to May. New Holland. Introduced in 1836.

C. flava.—A very pretty and distinct form for the cultivator, though regarded by some botanists as a variety of *cordata*. It is of erect, slender habit, with elongate ovate leaves sinuately toothed on the margin, the teeth spiny; the flowers are in racemes, the standard deep clear yellow, the wings much paler, or lemon-coloured. Flowers in March and April. New Holland. Introduced about 1848.

C. Henchmanni.—A hairy shrub, with short twiggy branches, covered with needle-shaped leaves, and bearing numerous axillary racemes of flowers, which are very ornamental, light scarlet, with a yellow mark at the base of the standard. Flowers from April to June, and sometimes onwards till September. New Holland. Introduced 1825.

C. ilicifolia.—A diffuse-spreading shrub, with oblong

lanceolate pinnatifidly spinous leaves, and bearing scarlet flowers, the standard marked with yellow at the base. Flowers from March to August. New Holland. Introduced 1803.

C. ovata.—A handsome shrub, with weak, ascending, winged stems, furnished with ovate-acute leaves, and bearing short racemes of showy flowers, usually scarlet, with the wings crimson. Flowers from March to May. New Holland. Introduced 1830.

C. spectabilis.—A very beautiful, small shrub, with slender, twining, or scrambling stems, the leaves of which are elliptic-lanceolate, obovate, or cuneate, and the flowers pale orange in the standard, tinged with crimson, the twigs being crimson; they grow in long, drooping racemes. Flowers from April to July. New Holland. Introduced 1839.

C. triangularis.—A beautiful, dwarf, spreading shrub, of branching habit, with sub-hastate leaves, pinnatifidly spinous on the margin, and the flowers in short racemes, the standard scarlet, the wings purple. Flowers in March and April. New Holland. Introduced 1830.

C. varia.—A dwarf, compact-growing species, with variable leaves; in some forms broadly ovate, toothed, and spiny on the margins, in others almost entire, and sometimes nearly round in outline. The flowers are very numerous, in short racemes, large and showy, usually orange, with crimson wings. Flowers from April to July. New Holland. Introduced in 1837. The variety called *C. varia nana*, of remarkably dwarf habit, is the best for a limited collection, though there are two or three other very distinct and beautiful forms.—(*Gardeners' Magazine of Botany*.)

Chorozema triangularis.

A FEW DAYS IN IRELAND.
LYONS.

Fig. 1.—FLOWER GARDEN AT LYONS.

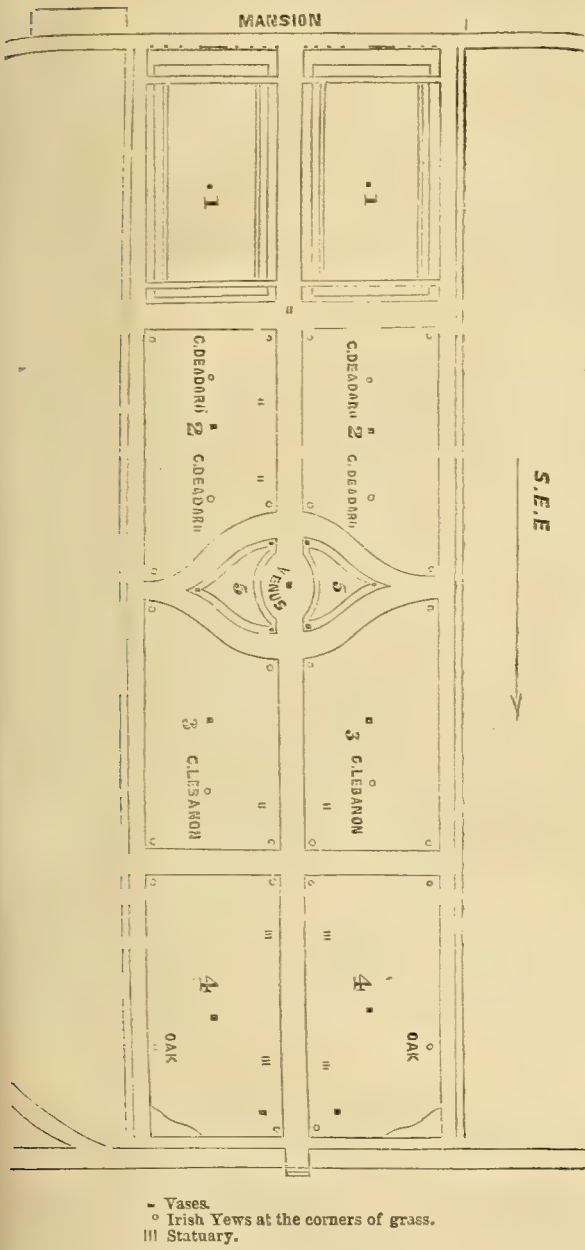

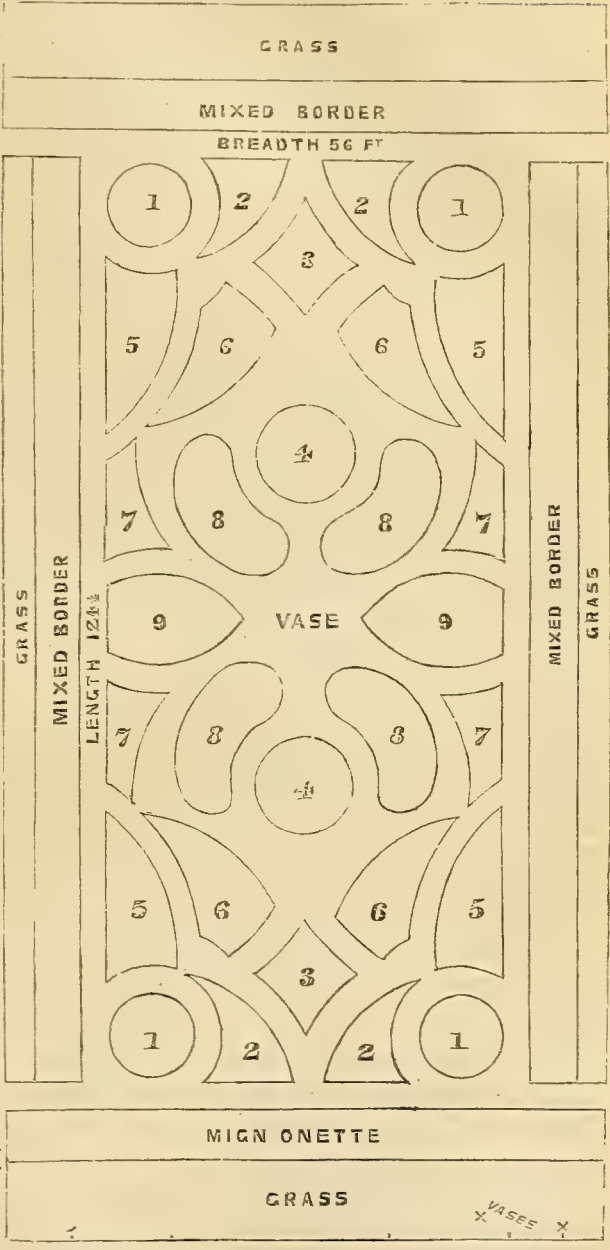

Fig. 2.—PLAN OF PANEL.

THIS very elegant and classic residence of Lord Cloncurry is twelve miles from Dublin and two miles from the station of Hazelhatch, on the Great Southern and Western Railway. The mansion is very handsome, consisting of a centre and wings connected together by colonnades, and is much celebrated for its rich collection of paintings and its gallery of fine statuary. We arrived at Lyons from Straffan by a beautiful approach, but too late in the afternoon to be able to note and appreciate all its distinctive beauties, or to examine and be delighted with the great improvements of superior cultivation and effective drainage accomplished and being carried on in the various farms of more than one thousand acres in all. The noble owner spares no pains, labour, or expense in this direction, and gives a lesson and an example of true patriotism by living almost constantly among his own people, and assisting every effort that has a tendency to elevate them in comfort and social respectability.

The site of the mansion is an elevated platform, but the whole surroundings with their rich plantations being somewhat level, no views of consequence can be obtained from it, unless on the flower-garden front, where after passing over an oblong flower garden 650 feet in length by 198 feet in breadth, which slopes down to a noble clear lake of forty acres, the eye rests on the beautiful hill of Lyons on the opposite side of the lake, which rises to the height of 680 feet, and from the top of which fine views must be obtained of the surrounding rich level country. From the flower garden glimpses are obtained of massive ruins on the side of the hill, the remains of an old castle or monastery, and possessing an extra interest as being near to the burial place of the family. We could not help thinking how imposing, nay, almost how impregnable, a castle situated on the top of such a hill would have been in the days of raids and forays, when might was considered to be more than three parts out of the

four of right, and when nothing was thought, in these "good old times," of the exhausting labour so imposed on serfs and vassals, as to send them prematurely out of that world which had been to them a scene of toil and of woe. Neither could we help reflecting how grand and picturesque a castellated mansion would have looked loftily placed on the bosom of that hill, commanding such a rich distant view of the surrounding country, and near at hand a series of terraces down to the beautiful lake. In these days of quiet and social amelioration, when comfort is even more important than security, and easy access to water, corn, and fuel more desiderated than even the most splendid views, we gradually become reconciled to the mansion of Lyons being situated where it is, as we feel there is an advantage on the score of prudential economy in looking over the lake up to the hill, instead of looking down from a rich colonnade near its crest.

Owing to the lateness of our visit, we will chiefly confine ourselves to the peculiar features of the large flower garden, the management of the fruit trees, and the mode of heating the forcing-houses; and thus, whilst touching on some of the distinctive features, help also to give variety to these sketches.

The flower garden, as already indicated, is bounded at one end by the mansion and a range of elegant vases, and at the other end by the splendid lake. The two sides are bounded by lawns meadows, and plantations, the meadow being one of the things a gardener would wish elsewhere, owing to the weeds that are apt to come from it. This oblong square is divided by a walk down the centre, 21 feet in width, and bounded on the sides by walks 10 feet in width with their suitable verges, &c. Three transverse walks at something like equal distances apart, would throw the whole space into four pair of oblongs; but a fine statue of Venus on a lofty pedestal being placed in the middle of the central walk, and equidistant from the mansion and the lake, the necessary curve round it breaks what might have been the monotonous straight lines of the oblongs, and secures a pair of curved triangles in addition to the oblongs, as seen at 5, 5, in *fig. 1*.

We here met with our new and very intelligent friend Mr. Lind, who kindly detailed to us many changes and improvements he proposed effecting, though the garden, as it was presented to us, had many charms, and chiefly for two reasons—first, because in combination with the new grouping system, there was full play given to the older and, perhaps, more simple and natural arrangement of flowers; and secondly, because each pair of oblongs was planted not only so as to pretty well balance each other, but so that each pair should be distinct and conjure up different associations.

Thus beginning at the two squares next the mansion, we find that the beds are grouped with bedding plants and separated from each other by walks of gravel, and that in addition each of these oblongs is surrounded by a border about 6 feet in width, planted chiefly on the mixed system with early bulbs in spring, numbers of bedding plants in summer, and having besides a number of fine plants of Lavender along the centre, and the sides well supplied with huge massive plants of evergreen Candytuft, *Aubrietia purpurea*, *Arabis verna* and variegata, and *Alyssum saxatile*, &c., which give the border a very rich gay appearance in April and May, and a furnished look in winter.

It would, therefore, be a pity to alter the arrangement of these borders, though we quite coincide with Mr. Lind, that no sticking-in of abundance of bedding plants during summer will ever cause these borders in autumn to vie with or equal the splendour of the grouped beds. If the labour-power would permit, we would reduce the fine old plants to more manageable dimensions, remove them to a reserve ground in the end of May, and ribbon or parterre these borders so as to be of a piece with the beds in autumn. The beds in the two squares 1, *fig. 1* have also rows, &c., of Tulips, Crocus, and Snowdrops in spring; and with the exception of Roses, &c., were filled with bedding plants in summer; and we quite agree with Mr. Lind in removing even Roses from such a parterre, as do what you will you cannot get them to correspond with massive beds of bedding plants in the end of summer and autumn. *Fig. 2* is a plan of one of the squares of *fig. 1*, and was thus planted:—1, all Scarlet Geraniums, with *Humea* for centre; 2, *Verbena venosa*, which generally grows strong in the moist climate of Ireland; 3, one bed with Roses, Perpetual and Moss, with a belt of *Salvia patens*, the other bed belted with a violet *Verbena*; 4, one bed Roses and *Salvia patens*, the other Roses and Lord Raglan *Verbena*; 5, all *Lobelia fulgens*—splendid beds in autumn; 6, two beds of

Amplexicaulis Calceolaria, and two beds of Golden Ball *Calceolaria* in fine order; 7, all *Manglesii* Geranium; 8, planted in lines, middle *Perilla*, then white *Alyssum* and *Tropaeolum elegans*; 9, 9, *Verbena venosa*. We think these large beds would have been improved by mixing with Flower of the Day or old Scarlet Variegated Geranium. If the borders were ribboned in straight lines, we should like more of the beds to be mixed, or edged, and that would increase variety; but then there should be a different style from that adopted in the two squares 2, *fig. 1*.

In the couple of parterres, 2, 2, there were fine beds of Roses, and a fine horseshoe bed of *Berberis aquifolium*, which looks well summer and winter. The main beds, however, are filled with early hardy bulbs; and then, as these decay, the beds are filled with bedding plants. Mr. Lind intended grouping all these beds in future; and as they have no border round them, a different style of planting should obtain from that adopted in No. 1.

The two beds, 5, 5, round the statue of Venus are filled with Roses, and, the row next the Venus are pillar Roses, and festooned together; then follow standards, half-standards, and dwarfs, so as to form a blunt pyramid of Roses. The break in the masses of flowers here is very pleasing, and prevents one being overpowered with dazzling colours, and there is no chance of wearying from the monotony of the splendour presented.

The pair, 3, 3, is on grass, and the parterres may be called transition gardens. Here again were beds of *Berberis* and *Hypericum* (St. John's-wort); fine beds of China Roses; Dahlias; mixed bedding plants in lines; herbaceous plants in varieties; Sweet Peas; Hollyhocks; and beds of *Phloxes*, &c.; putting one in mind of, and in love with, our old-fashioned flower-gardening. Mr. Lind contemplated a better arrangement of many of the beds, in addition to Hollyhocks, Dahlias, *Phloxes*, &c., so that the beds should be gay all the year round—such as mixtures of *Delphinium formosum* and *Verbena venosa*, both of which stand the winter there well, and the *Verbena* would just be coming strong when the *Delphinium* wanted pruning-in.

The pair, 4, 4, are chiefly old herbaceous plants and deciduous shrubs and trees. Among the latter are some fine old *Laburnum* trees, which are stumped-in close every year, and yet bloom most freely on the young wood, and, what is more singular, produce endless sports, generally having three or more distinct forms of wood and colours of flower on every tree—the large yellow and the small yellow, and the pink and purple as well. Mr. Lind playfully hinted whether inquiring into the causes of such eccentric variation might not be a pleasant relief from the vexed question of the cause of variegation in plants. We understood there was to be a change in the parterres, 4, 4, by throwing the beds into grass near the lake, which we feel sure would be a great improvement, especially if graced with a few evergreens and Conifers, as there are plenty of beds to require an immense number of plants to fill them well. The Irish Yews at the corners of the parterres come in well. The combination of the new grouping system with the old mixed system is very pleasing to a stranger, more especially as the systems are kept separate and distinct. The vases and statuary give a light and elevated appearance to the whole.

We just saw enough of the kitchen garden to be satisfied that there was a good supply of all vegetables for family consumption; but the fruit trees having arrested our attention, and Mr. Lind having had much practice in root-lifting and root-pruning, &c., we will now devote a short space to that subject. The first we shall refer to were fine-looking Apricots, with short-jointed, well-ripened wood and prominent buds. Previously the wood did not ripen well. On examining the border it was found to be well flagged 3 feet from the surface. The soil and the roots were dry; but the latter were deep, and in a sad state with warts and suckers, from deep cultivation of the borders. The warts and suckers were carefully removed, the roots carefully traced out, the lower soil well firmed, much of the surface soil removed, and the trees were just not raised altogether, 2 feet next the stem being left, and the roots were nicely packed in new soil a foot from the surface.

Then, Pear trees were greatly improved by the following process. They had been root-pruned more than once—that is, a trench had been dug round the stem, at 3 feet from it, and all roots cut through. No attention to drainage being given, no encouragement to surface roots, the new roots formed went down straight as a line after moisture, into the subsoil, and flower-buds and good fruit were things rather to be thought of than obtained. These straight-downward roots were carefully raised as far as

possible, a foot of open drainage was packed underneath, and the long roots brought near the surface, as in the case of the Apricots, with marked success. A similar course was adopted with Plums and Peaches. In such a moist climate, dryness at the root near the surface, and frequent raising and root-pruning young trees, are great essentials to success. One of our old tutors in Staffordshire lifted his Peach trees every other year, and thus, though the trees were rather small, secured plump buds, stubby wood, and freedom from canker and insects. Mr. Lind does all that work, if possible, early in autumn before the leaves begin to change much, and thus accelerates the ripening of the wood, and finds an advantage instead of a disadvantage the following season. If he commences in the beginning of October, he shades the trees for a short time in bright sunshine, and uses the syringe pretty freely, to prevent the leaves falling prematurely, and thus the fine new roots will be running in the fresh, warm, surface soil, before even the leaves all fall.

R. FISH.

(To be continued.)

DOUBLE LESSER PERIWINKLE.

I SEND you by this post a box containing flowers of the double blue Vinca minor, hoping you will inform me, for my own satisfaction and also for that of my friends, if it is a plant in general cultivation. I do not remember having seen it before this year.

It is one of the most beautiful plants I ever saw for early spring blooming. The plant I took the enclosed flowers from is growing on a block of wood on the lawn, exposed to all sorts of wind and weather, and has been producing hundreds of blooms since the middle of January last. It has now quantities of beautiful expanded blooms upon it, and will evidently continue to flower for some time to come, there being large numbers of buds daily making their appearance. The plant grows very compact and quite circular, and, I think, would be found an admirable acquisition for suspended baskets in the conservatory, or cold greenhouse. The shoots are about 2 feet in length, of slender habit, and produce racemes of blooms from the crown of the plant to the extreme point of the shoot. The foliage is small, of a bright dark green, and beautifully contrasts with its lovely hepatica-like flowers. I have been an admirer of spring-flowering and rock plants for many years, but I do not remember any plant more deserving of general cultivation.—HENRY W. BROWNE, Boughton Street, St. John's, Worcester.

[The specimens, abundant in number, sent by our correspondent, we consider a very desirable acquisition, both for rock-work in the open garden and for baskets in the conservatory, if the plants will flower true and as abundantly there. In some old florists' catalogues we find a double purple variety of the Vinca minor mentioned, but we have no remembrance of it in modern catalogues.—EDS. J. OF H.]

GARDENERS' SOCIETY.

I MUST thank your correspondent "G. A." for bringing the above subject before the gardening public, and I hope it will be well responded to, as I know the want of unity in the profession has often been felt and commented on by numbers of gardeners with whom I have come in contact. Could not the Gardeners' Benevolent Society be extended to embrace the idea in a great measure?

Two or three years ago the education of gardeners was criticised rather severely in the columns of a contemporary, because some of those hybrids between a groom and gardener applied for a situation in letters containing some wretchedly bad spelling. This was too hard upon gardeners as a class, and would not have happened if public examinations in which first, second, and third class certificates were given, had been the order of the day. Should such be adopted, we should find the right man in the right place more frequently than we do now.

How often do we see the man who has worked his way upwards from the stokehole through different gradations to the position of confidential foreman, after qualifying himself in his leisure hours by studying vegetable physiology, botany, chemistry, &c., and another, without study, and with half the years of practice, but with good private interest, gain the position in society the former should have held? If a certificate were required from a recognised board of examiners, abilities would become more

prominent in the great competitive labour market. Again: Gardeners, from the very nature of their employment being much isolated from their brother gardeners, particularly in country localities, the stated times of meeting at head-quarters of sub-districts would tend to bring them more together; and the exchange of ideas could not fail to be beneficial.

Also, if a fund for sick and disabled members could be added so much the better, as it is very lamentable to see a once-respectable man in his old age come to want, as is often the case. Gardeners when young are not thought capable of filling a head place, consequently they have not the chance of providing for a rainy day so well as persons engaged in many other trades and professions.

I will conclude by hoping that the importance of the subject will cause it to be well ventilated.—J. A., *Hants.*

[We are enabled to state that steps are being taken to effect the establishment of a "GARDENERS' SOCIETY."—EDS. J. OF H.]

ANIMAL HELPS IN GARDENS.

THE HEN.—A fowl that devours greedily all kinds of insects in the egg, larva, or chrysalis state, and in most cases the mature insects. Woodlice hens are partial to. I have known a single hen devour a gill (quarter of a pint), in a few minutes, which I had caught by the simple and old-fashioned contrivance of putting a boiled potato in a 32-sized flower-pot, and placing a little hay loosely over it in the pot. This, along with pouring boiling water down the walls of a Mushroom-house, effectually eradicates the troublesome woodlice. When it can be done, hens will speedily clear dung of woodlice, and a large quantity of larvæ or maggots more or less present in dung. They not only catch all they see, but they search with their feet for more.

Were it not for their ardour in searching for prey with their claws, and scratching such deep holes to cool and clean themselves, I should have no objection to their entering a garden; but I have tried them there, and was glad to be free of them. They scratch anywhere, and never in the right place; destroy seed-beds completely, eating the seeds; and they will pull currants off the trees for mischief, and anything that looks like "grub" they tamper with. In return, they make quick work and good of snail or slug eggs. I have no proof that they devour the perfect insect, though I have watched and put them in their way.

In a garden they are a nuisance, and do more harm than good. I have known people wrap bantams' claws in a kind of leathern bag, so as to make them web-footed like ducks, and I can vouch for their then doing good service. A couple even then are enough on an acre of land; and they must be fed twice daily, and a supply of water provided.

DUCKS.—These are wholesale devourers of insects, the slug, and beetles occasionally, but not when other food is plentiful; the larvae, however, they gulp down should they put in an appearance near the surface. They also destroy wireworms and dew-worms, but seem to respect them when fecundating in July; and they put their bills into Strawberry-beds, breaking some plants off or trampling them to death and into Thrift and Box-edgings, and mostly suck in something, as often bits of sand and quartz as anything else. In reality they are useful in a garden, and of great service to the gardener. In point of damage they break succulent plants, as Calceolarias, and sodden the ground by their putting some four pounds pressure so frequently in one place, and the dirt made by them is not pleasant to the eye.

A couple of ducks are enough in a garden of one acre, and they may rear their young until five weeks old, when they must be put out of the garden altogether.

It is advantageous to have a small pond in which they can swim and wash themselves; but it is not absolutely necessary, for a shallow galvanised basin (ours is 2 feet by 6 inches), will answer the purpose of drinking, a wade-through, and a wash besides. They must be fed once daily in the morning in summer, and twice daily in winter during severe weather. The reason they are not to be fed at night is to make them forage.

Where there is the convenience of a pond, ball, pail, and other small breeds are not only ornamental but useful; and as they are shyer than the Aylesbury, Rouen, &c., their excursions are taken during early morn and night, but they never wander far. Even they must be fed at least once in twenty-four hours.

WATER HEN.—Shy, but insects and aquatic grasses form their

daily fare. A pond and an isle with undergrowth are all they require. Geese are worthless, and swans are little better.

WATER RAT (*Arvicola aquatica*).—"Nay, it eats young ducks and goslings," say old wives. But for once the old wives are wrong. The water rat is a sportive inoffensive creature—a water-insect and aquatic-plant-devouring animal, valuable for eating grasses that choke-up brooks and pools; and it, with wild ducks, will clear any stream of Anacharis—that plague which threatens to close the angler's sport. By-the-by, we had some Water Lily (*Nymphaea alba*), from Cambridgeshire, out of the sluggish streams there, and planted them in a pond. To our mortification the Anacharis soon filled it; but thanks to the Normandy ducks, they cleared it sharply, not forgetting to destroy the Lilies also to the root, but they come up again.

PEA FOWL.—A swaggering gentleman, and a coward and great bore. It is of no use trying to grow anything where there are many of them; yet they devour snake and viper eggs, the young and the mature reptile also.

GUINEA FOWL.—Too shy and tender for a garden, not given to scratch except in basking-holes, but of little value to the gardener. Though they are large insect-consumers, yet they partake too much of the pheasant and partridge to be of much utility.

OWLS.—Very valuable; but who can pinion one, and put a false wing on? Very, very useful in a wild state, yet useless when caged. I have heard gamekeepers assert that owls take young rabbits and partridges. Be it known that they do no such thing. I have watched them for hours when alone by my bothy door, and though I have seen a covey of partridges (and young enough), and young rabbits in the paddock adjoining a wood; and the invariable chosen prey of the owl (horned, the largest, and screech owl too, not excepting the white), was a mouse. Happily the worthy owner did not believe keepers to have much knowledge of owls, or they would soon have been swept away. He spread his wing alike over the fowl and brute as he did over the fatherless children and widow. Owls, though solitary birds by day, court rather than shun the habitations of man when protection is afforded them. The screech owl harboured in an unfrequented tower over the laundry at the place above alluded to, and I have known them shelter in grottoes, and, in one instance, in a church steeple. The horned owl hides itself in hollow trees, and the barn owls also select a secluded resting-place where they breed, and to see them sally forth at night in search of prey for their young is an instructive sight. To see them skin a mouse before it is given to their young may cause a shudder; but, their catching a rabbit or partridge is what I should very much like to witness. The food of owls is the smaller quadrupeds of the mouse tribe, but rarely birds and never are they poachers of game.

HAWKS.—The sparrow-hawk is a capital tenter of the smaller birds, for though they may mock him in a pinioned state, yet they dare not follow their nefarious practices, or Mr. Hawk puts in his veto. A basin of water and raw meat is all the hawks need. I have tried none of the larger kinds.

THE CUCKOO is a first-class insect-consumer, and a scarer of small birds. Cuckoos may be reared with boiled eggs and sopped bread. But do not pinion one; rather clip its wing, and towards autumn if it cannot fly clip the other and let it fly to other climes, to return again in spring.

GUILLS.—I have had three kinds in gardens. The grey, white, and black-headed, and a smaller kind under the name of a tern. The black-headed are good, the grey next, and the tern best of all. The tern is about the size of a jackdaw, and becomes very tame. When the gardener is digging it follows, picking up worms, slugs, and grubs. The gulls never become very tractable, but they are continually on the look-out for snails, worms, insects, and mice. The gulls are the only bird that I know with a pointed beak that devour animals. They will soon clear a garden of mice, and they do not object to take a sparrow on the sly. A sparrow they devour whole, head foremost, and they relish young thrushes and blackbirds. In fact their gluttony is unbounded; but as their food is insects and small animals they are invaluable to the gardener. Occasionally they will take the heart out of a Cabbage, but beyond that they do no harm in a garden. Two are enough for an acre.

Gulls require fish when young to rear them, and anything afterwards you please to give them, cereals excepted. They should have a basin of water to drink at, wade through, and wash in; but a pond they are averse to, on account of the fresh water being colder than their native element—sea water.—G. A.

GISHURST COMPOUND.

MR. WILSON says that he has proved that 8 ozs. to the gallon might be applied so as not to injure buds, but I have found out it does so to a great extent; for I dressed the trees in an orchard-house about the last week in December, using 8 ozs. to the gallon, and on some of the trees it took a great effect. From some of the Peaches three-parts of the buds fell off, and, I think, there is hardly enough left for a crop. The Pears seem the same, for about half the buds became black and fell off. The Cherries, and Plums, and Apricots do not seem the least injured. I brushed them all softly with a small painter's brush.

I am not the only one about here that it has taught a lesson to. The trees were all in pots, and have done very well before every year. I will take good care to use no more Gishurst. I think some of your worthy friends, such as Mr. Rivers and a whole host of others that so highly recommend it, could not have thoroughly proved it. I believe that I used it the same as directed in this Journal time after time—8 ozs. to the gallon for trees at rest.—S. P.

[We think you have formed too hasty a resolve against the Gishurst compound. This winter has been so mild, that even in December Peach trees under glass had their blossom-buds as much swollen as they are usually in February. Wait until the end of the year before you add a Mede-and-Persian law against the Gishurst to your gardening code.—EDS. J. OF H.]

EXTRACT from annual report of the Van Mons Society of Belgium. Printed at Brussels. Tenth publication.

"In 1859 appeared for the first time the destruction produced by the Scolytus, ravages which were not perceived till then, so little was it thought that this insect would attack Pear trees. In cutting-up one of these trees, the inside was found entirely perforated, and Scolyti were found measuring 6 to 7 centimetres long, and 3 to 4 centimetres in circumference. Various remedies have been tried to destroy this hidden enemy. The trees have been stripped of their bark to the inner rind, and washed with milk of lime; but what has produced the best result, is a composition which we received from Scotland under the name of 'Gishurst compound,' which, diluted with a certain quantity of water, was introduced with the small syringe into the perforations caused by the Scolyti, and destroyed them."

WORK FOR THE WEEK.

KITCHEN GARDEN.

EVERYTHING connected with this department should now be kept in good order. Take every opportunity of eradicating weeds; hand-weed where practicable, as it more effectually answers the purpose than hoeing and raking. Cut the Box-edgings and keep the walks well rolled. *Basil*, a warm sheltered spot may now be chosen to sow in the open ground; but being rather a tender annual, it is generally the best plan to sow in pans or on a slight hotbed and afterwards to plant it out. *Beans*, earth-up the early crops, but before doing so lay a little soot close to the stems. Timely earthing will also prevent the wind damaging them. *Borecole*, make a sowing for the first crop, what is commonly called the Scotch Kale is the best variety. *Broccoli*, most of the varieties may be sown about the end of the week. By sowing early there is time for a second sowing in case of failure. *Cabbage*, pull up any of the plants that are running to seed in the autumn plantations, and fill up from the reserve-bed. At the same time stir the soil between the plants and earth them up. *Carrots*, thin out those in frames, and give a plentiful supply of water when dry. In sowing the main crops put in the seed rather thickly, as it is more liable to fail than any other kitchen-garden crop. *Celery*, the main sowing for the winter crop should now be made. Continue to prick out from the early sowings. *Dwarf Kidney Beans*, a sowing may be made on a warm sheltered border where the soil is favourable to early crops, or a sowing may be made in pots for planting out as soon as all danger from frost is over. *Lettuces*, give air to the plants in frames night and day in mild weather. Loosen the soil about those planted in the open ground. *Onions*, sow the Silver-skinned on a poor piece of ground to produce picklers. Plant into beds the autumn-sown or those sown in boxes in the early part of the year. Draw shallow drills, and lay the roots of the plants in them at regular distances, after which cover them with fine soil. *Peas*, sow any approved sorts

for succession, but after the early part of the season, Knight's Dwarf Green Marrow should be sown as a delicious sort, but other and quick-bearing sorts may be sown when a large quantity is wanted at each successive gathering. *Radishes*, keep up a succession by sowing a few once a fortnight. *Sea-kale*, remove the covering when the produce is gathered. If there is any yet remaining to be covered let it be done before it grows much. *Turnips*, thin out those sown in frames, and give them water when necessary.

FLOWER GARDEN.

Patches of showy hardy annuals should now be sown in vacant places, which usually are to be found in herbaceous beds and in borders of the shrubbery. Double Poppies of various colours, Lupines, Sundowers, African and French Marigolds, Clarkias, Gilias, Erysimums, Collinsias, Silene, and Nemophila are excellent for that purpose. *Campanula stricta* appears a desirable plant for flower-garden purposes; its colour is light blue, height about 6 inches. This, together with *Salvia chamædrioides*, as well as the blue *Anagallis*, should be cultivated in abundance, particularly where beds are encompassed with gravel, and now that the *Verbenas* produce so many warm-coloured flowers. Cultivate the different sorts of *Mimulus*; several of the strong-growing sorts do well for damp situations in the shrubbery, and, from their warmish colour, add apparent depth to the scene. Plant *Gladioluses* and *Ferrarias*. Plant evergreen shrubs if you are obliged, and, if so, take care to let every fibre be carefully preserved; have large balls of earth, and holes dug much larger than the ball will fit into. Attend well to watering, and fix the stakes to prevent the injurious effect of the shrubs being wind-waked.

FRUIT GARDEN.

The following is a method of which many may avail themselves to obtain Grapes nearly equal to those grown in the most approved structures. All that is necessary for the purpose are established Vines against walls, a common hotbed-frame or two having three or four lights, a load or two of dung and leaves, and a few plain tiles. If the Vines are pruned, which they should have been before this time, make a bed of leaves and dung of the size of the frame, about 4 or 5 feet high, and 2 feet from the wall; use the short dung at the top, and put on the frame immediately. After the heat is up fork it up a little once or twice; and if it become dry, water it slightly. After the strong heat has somewhat subsided cut notches in the back of the frames, and bring down the branches of the Vines. A trellis should then be fixed inside at about 6 inches from the glass, to which the Vines must be tied. When this is completed close the frame, and let it remain unless the bed is very hot, when a little air must be given until the buds begin to push; after which they must have air according to the state of the weather. When the buds are about breaking, the dung should be covered with tiles or slates to keep down excess of heat and steam. When it is necessary to thin the Grapes the lights can be drawn off.

STOVE.

If any plants in this structure require propagation seize an early opportunity. Keep a moist atmosphere with a sweet and regular circulation of air, using abundance of water about floors, and syringing frequently air-plants or others suspended. Shut up with a solar heat, if possible, of 80° towards three or four o'clock.

GREENHOUSE AND CONSERVATORY.

The regular admission of air, qualified in amount by the state of the weather and the period of the day, will not only be advantageous to the health but conducive to the preservation of the blossom of the many elegant plants which decorate the conservatories at this moment. Continue to shift those greenhouse plants which require it. The process of shifting is generally as follows:—A few potsherds to be placed at the bottom of the pot, and then a layer of the rough turfy portions of the soil. When the plant is in hand a portion of the old soil is carefully removed by the fingers, or by gently patting the sides with the hand so as to loosen the points of the fibres if they are at all matted. Then place the plant in the pot, so that the top of the old ball of earth may be level with the rim of the pot; fill-in with whatever soil is most suitable in a rough state, and gently but firmly press it down, finishing-off quite level about half an inch below the rim. Give a moderate watering with a rose to settle the soil about the roots, and the operation is then finished.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

GAVE a little manure water to Broccoli beginning to swell. Sowed succession Peas and Beans, also Spinach. Regulated and made up herb-beds. Planted new beds of Mint, as on cold stiff soils it is apt to give way if not frequently renewed, and a gardener might as well be without Parsley as without Mint. Sowed the main crop of Parsley. Planted-out Peas from boxes, and staked as proceeded. Watered Cauliflower out of doors and in hand-lights, that in the latter growing fast, and almost threatening to be in as soon as some of the Broccoli. Planted a small bit more of Potatoes under cover; have still a few late ones to plant out. Pricked-out Cauliflower and Lettuces from a Carrot-bed under glass, which will enable us to keep this second Carrot-bed closer to get them in sooner. Planted the Lettuce at the foot of a wall, so as to succeed the winter ones, now very nice.

Planted-out a piece of Fraser's Batavian Endive to obtain a little seed; this being the very best among the broad-leaved Endives for compactness and hardness—in fact, for sweetness, crispness, and hardness it beats all other Endives hollow. We have had it in April and May on a north border looking like huge pats of yellow butter, and almost as sweet, by merely placing a 24-sized pot over each plant, and stuffing the hole with a wedge of moss. On applying to Mr. Veitch for a pinch, he replies, "Sold out," but that is just a reason why amateurs who grow little, and like to make sure of a salad in winter with but little trouble, should try and obtain a little pinch. It is sure to be scarce for a time, though it is now a number of years since our good neighbour distributed it. If any one should save a few plants for seed they will be sure to be disappointed if they do not net shortly after the plants show flower, if there are such things as birds near them. Two years ago the rascals got under our net, and ate up almost every seed in the milky state. Let them alone for finding a good thing! A few Lettuce stalks that we cared nothing about were untouched—we say cared nothing about advisedly, because in most small gardens it is cheaper every way to buy seeds that can be depended on from a seedsman, instead of bothering and saving your own. We have often seen plant-houses and fruit-houses a perfect mess for months from seeds drying and perfecting in them, and a few shillings, less after all than the worth of the labour involved, would have bought all that was wanted. Of course, if there is a *must be* it must be; but in these days of the division of labour, seedsmen by trade can save good seed cheaper than the man who has myriads of other things to attend to. In rather new varieties or where it is doubtful if the real Simon Pure can be obtained, there may well be exceptions; but all our great seedsmen, even as a matter of trade, are as anxious to send out only the best articles, as their customers are to receive such.

This blanching of Endive has reminded us of the Sea-kale we mentioned the other week, placing rather large common pots over some in the open air, with a little earth round the bottom of the pot, and turf across the top. Well, on looking at it yesterday to see how it would come in to succeed some under litter, we found it was from 2 to 3 inches high, and would be long enough in another week; but it was coming neither white nor green, but a sort of go-between purplish, and all from a very simple cause which we never thought about. The heat of the sun had dried and shrunk the turf, and thus a little light reached the Sea-kale, which prevented thorough blanching. Had we stuffed a plug of litter or moss in the hole we should have had it white enough. Pots of any size being now wanted for potting, for sowing seed, and for pricking-out seedlings, we managed to obtain a few small oyster-barrels instead, which will do better than pots, especially with a turf on the top of them, and hanging over all like the large blue bonnet of a Highlandman, so as to prevent the sun shrinking the staves, for that would let the light in. Covered up, also, several rows, showing fine heads, with a ridge of ashes 6 inches deep, and a little dry earth from between the rows over it; and in this case, as soon as the smallest bit of Kale appears, the head will be in prime case to cut. There is nothing better for obtaining delicious Sea-kale than a covering of 8 inches of bog earth, and cutting when 6 inches long, which can be easily known by seeing the little hillocks made by the growing Kale. Sowed a lot of Sea-kale seed in rows 18 inches apart. This, when thinned out, is a more profitable way of growing it than in beds. In good light soil it will be good stuff for forcing the first winter. In cold soil on a north exposure it will require two summers.

Dug ground for sowing more Asparagus, as, when much is

forced, there is no other plan for keeping-up a succession. Forked the soil, and earthed-up Cabbages, and uncovered Potatoes during the day, now about fit for table, those in pots lasting out well. Watered Mushroom-beds; bearing still pretty well. Ought to have made up another bed; but just now there is such a demand for extra heat from the little fermenting material that falls to our share, that we could not spare any droppings.

FRUIT GARDEN.

Some of the Strawberry-beds, having more rough leaf mould placed between the rows in winter than they could manage, had the ground hoed, and the rough extra material raked off and put in the bottom of trenches that will come in for Celery some day. Daubed buds of Cherries, Pears, &c., with a little weak Gishurst, and soot and lime, partly to keep insects from them, but chiefly to keep the vermin of birds from them. We had a row of dwarf Plum trees as fine a sight as ever we would wish to look upon; but the fruit will be few and far between, as scarcely a bud was left, even though a net was thrown over them. One dark evening some boys batfolded and caught from eighty to ninety of the gentry, and we asked no questions as to what they did with them. It is singular with what pertinacity they will keep to some things. Some other Plums were not touched at all, and the same as to vegetables. Two rows of fine Marrow Peas had to be sown again, and now, in addition to trenches along the rows, a narrow net is placed above the branches, and still through net and altogether you will see the marks of their bills at the young sprouting Peas, whilst there seem to be much more tempting rows of other kinds close at hand, which have never been touched. In this one would almost think there was more than the choice and selection of instinct. And yet, for all that, did they moderately only take their share, we would willingly forget and forgive, and even do something more, so delightful now are their sweet notes morning and evening. Regulated Strawberries less or more every day, as when fruit is gathered every day, besides watering, some pots will require taking out, and some others taking in. Others of our attendants knew something in the way of selection as well as the birds; for if a slug or snail has scooped out a small hole in a Strawberry, there is every probability that it will be in the best Strawberry in the house—just such a one as you would like to have as the crowner to a dish. There is no method of getting hold of these gentry except taking a candle at night and looking for them, and they will be easier found if there should be such tempting baits laid down after work hours as a handful of brewers' grains, or some buttered young Cabbage leaves.

Further disbudded trees and thinned fruit in Peach-house, and for a fortnight have seen no more of the brown beetle. We found it taking hold on some small trees in pots in orchard-house. The trees were placed in a small box-house; half a bushel of bruised laurel leaves were placed on the bottom of the box, and the door shut close, and next morning there was not one insect alive. For plants that we can put into this box, we have found no kind of insects that can stand the fumes from the laurel leaves; and one advantage is there is no smoking or dust of any kind thrown on the plant. A slight skiff with the syringe afterwards makes the plant clean of all vermin. There is just a chance of some eggs remaining in a corner. We think for such purposes, having a stout calico cloth painted to make it stiff to keep in fumes, and then wrapped round a plant, a few laurel leaves would clear them more safely, often, than smoking would do; but a small plant could thus also be easily smoked. The great drawbacks of cleaning plants by syringing with any washes are, that unless the liquid is clear a sediment is formed, and the insects knocked down are apt to crawl up again.

Potted Vines, smaller and larger. Regulated Figs swelling fast, leaving those out of doors still covered with laurel twigs, and thinned Grapes, reducing the number of bunches as well. Planted out one bed of strong Melons; and the second bed having been filled with Verbena cuttings, in semicircular drain-tiles, which were struck, removed them, forked over the bed, and introduced the soil to heat ready for planting. The minutiae of our mode may be interesting to some. Our frames being about 10 inches deep in front and 20 inches behind, the most of the soil should be beneath the level of the bottom of the box. For this purpose the frame stands on a wall or ridge all round, a foot above the bottom of the bed. Supposing the bed inside to be 5½ feet wide, a space in the centre of 2½ feet wide is made deeper still to the extent of 6 or 8 inches or more. A slab is placed behind and in front of this; and the extra dung is placed

at the back and in front of these slabs, and between them and the sides of the frame. This leaves a well or gutter in the centre, between the slabs, of 2½ feet in width, and 1½ foot in depth for soil. We find this all the length of the bed is generally enough for Melons. When filled with earth the edges of the slabs are covered, and a couple of inches or so spread on the dung, back and front. If we wish to give more earth we have only to lift up the slabs and take out the dung at the sides, but we very seldom do so. We think that the plan has two advantages. The earth in the centre is kept warmer with a less proportion of dung, owing to the dung at the sides inside being almost as high as the surface of the earth: and again, the roots being mostly confined to the narrow space between the slabs, there is less encouragement given to an excess of mere luxuriance, whilst there is enough of vigour to secure well-flavoured handsome fruit. Weight for weight, Melons grown in large pots will generally be richer than those grown in a large bed of earth; and this curtailing of the feeding-ground in a pit or frame secures some of the advantages of the pit, and dispenses with much of the extra and constant attention that pits require over common beds.

ORNAMENTAL DEPARTMENT.

Besides potting, regulating, and moving, the chief work has been placing tubers of *Achimenes* in heat, bringing tubers of *Dahlias* to the floor of a vinery beneath a stage—that is, the general bulk, moving the *Verbena* cuttings referred to under calico to harden, planting out struck *Verbenas* singly in a bed to grow for six weeks, putting in more cuttings, potting-off variegated and Ivy-leaved *Geraniums*, planting lots of *Scarlets* in earth pits; and so little are we yet thinned, that more trenches must be dug for them. Watered slightly those *Calceolarias*, &c., in earth pits for the first time; most doing very well, and rooting nicely.—R. F.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

SKIMMIA JAPONICA BLOOMING BUT NOT FRUITING (*Elba*).—We are surprised at this, as with us it seems to set and perfect its fruit in greater abundance than we wish it, as we think by so doing it retards its growth. Perhaps you keep it too warm. We treat it much the same as Cape Heaths, inured to strong currents of air every day. The thermometer is above 32°. The soil we grow it in is a mixture of peat and loam, with more than a usual proportion of sand. Too much coddling is its bane; and treated as a stove plant, we believe it may have refused to fruit.

LIQUID MANURE FOR ROSES AND TENDER SHRUBS (*Idem*).—The drainage of a farmyard is the best of all liquid manure for Roses, but it ought to be given clear and not thick and muddy. Tender shrubs will not want it, as rampant growth is not so advisable with them as a good ripening of the shoots. Ordinary soil is therefore quite good enough for them; and in some cases a very poor sandy soil is advisable for tender shrubs, manure water being only wanted for swamp plants, and, if they be tender, most likely clear water will be more beneficial.

ANNUALS AND PERENNIALS FOR A SMOKY ATMOSPHERE (*Idem*).—Most of the common annuals, as Candytuft, *Convolvulus*, French Marigold, and the like do pretty well. Asters do not do so well. Of perennials, *Chrysanthemums* are unquestionably the best—in fact, it has often been a question if they do not succeed better in a town than in the country. *Dahlias* grow not amiss; and if the ground be moist *Phloxes* succeed pretty well. If the soil be good and the atmosphere free from all other noxious impurities excepting coal smoke, most of plants will do; only it is not advisable to plant many white-flowered, as *Rockets*, *Stocks*, &c., as they so quickly become soiled.

MEYENIA ERECTA AND *VINCA ROSEA* LEAVES TURNING YELLOW (*F. J.*).—There must be something wrong, or the leaves of your plants would not turn yellow when the plants are in flower. The *Vinca* especially is an evergreen shrub in its way. If the plants have been forced hard to flower thus early, and perhaps placed in a draughty greenhouse, they would suffer at once, or even if kept in the stove. Very hard forcing, and perhaps something the matter with the drainage, will occasion the sudden falling-away of the leaves. Your plant is *Saxifraga sarmentosa*, and probably the variety *cuscutiformis*, a favourite plant with some cottagers, and called by them "Mother of Thousands," but we could not be certain without seeing the flower.

PRUNING CEDAR OF LEBANON (*M. A.*).—It is certainly wrong to cut these trees at all; but if it must be done when they encroach on a walk or other place, then August is the best month for pruning them. It would be advisable to cut-in some of the limbs to within a short distance of the bole, and leave others overhanging the cut part to conceal it. Do not shorten all to one length, as a shorn look must be avoided; and if you can manage without cutting them at all so much the better.

SOWING QUERCUS PHELLOS (*M. A.*).—Sow the seeds of this, the Willow Oak, at once in deep pans or boxes, and do not moisten the soil too hastily if the acorns have been kept dry. If you have a large quantity they might be sown out-doors. It is always best to sow acorns when gathered, few seeds suffer more from being kept dry than they do. When it is absolutely necessary to keep them some time before sowing they should be buried in sand, and that neither too dry nor too moist.

VARIOUS (*S. R. S., Taunton*).—Superphosphate of lime will be beneficial to Geraniums and the other flowers you name. Sprinkle a dessert-spoonful on the surface of the soil round each plant. Syringe your Peach trees with a weak solution of Gishurst compound or with tobacco water to kill the green fly, as soon as the fruit is set. Pigstye drainage is too strong for flowering plants unless much diluted—about one gallon to eight gallons of water, and we would not apply it at all to Strawberry plants; but it may be given to Asparagus and Onions, between the rows, diluted—about one gallon to four gallons of water.

FLOWER-GARDEN PLAN (*S. E. L.*).—We purpose having it engraved and published next week, with a brief note on the planting.

LEAVES OF CINERARIA INJURED (*Curragh Camp*).—The leaf seemed to be infested with a scale, that looked almost like young woodlice. We have sometimes seen young woodlice on the leaves when the plants were grown in old brick pits, but except making a few holes they did little harm. These, however, we should imagine stick more closely, and should be syringed off by the plants being placed on their broad sides. It is not common for Cinerarias to be thus infested, and it is more strange from being common in the neighbourhood. With freedom from frost, coolness, and moisture, Cinerarias are little troubled with insects. Heat and dryness will bring them in shoals. There are so many "Amateurs," that looking back to such a signature to find what we want, would require no end of trouble and time. We are anxious to oblige to the utmost, but when correspondents make references, they will greatly oblige by giving the page and the volume.

PIPES REQUIRED FOR HEATING (*A Subscriber*).—We think that to keep a conservatory 24 feet high, 48 feet long, and 22 feet wide, warm for plants in bloom in winter, if span-roofed, with much glass on the sides, and the pipes as you say beneath the floor, you would require at least 600 feet of three-inch pipe instead of 370; but much will depend on the above matters. It will require more heating surface if the pipes are buried.

COLEUS PLANTS DAMPING-OFF (*A Subscriber*).—We can only conclude they have not had air and heat enough. They will not do much good under 60°. If we knew the treatment we might say more. Were they chilled too much in the journey?

SYRINGING WITH CLEAR SOOT WATER (*H. M., Lyme*).—“R. E.” says syringing with clear soot water is a great preservative against all kinds of insects, but it will not kill them when there. It must not be used too strong for *Azaleas*. He often makes it pretty strong, and dilutes as he uses it. But for general purposes a peck of good fresh soot will do for a hog-head of water. The following is the process of making it:—Place it nicely sifted in the tub, mix it with enough of water to form a paste with an old birch broom which causes it to mix with the water thoroughly and intimately. Then pour in the water and stir with the broom as you proceed. This will give you soot water but not clear, and about half as much or so of fresh lime powdered, and stir all well together. In a couple of days there will be a little film of chalk and soot on the surface of the water; remove that and the liquid is fit for use, as clear and bright as the best sherry or the sparkling pale ale some people like so much. The lime so clarifies the soot water that not a particle of black will be left on the foliage, though smelling strongly of ammonia. For some things you may use it stronger than the above, but it will be strong enough for Beans, Cucumbers, &c.

MOVING A LARGE PYRUS JAPONICA (*M. S.*).—You may enclose both the *Pyrus* and *Magnolia* for your conservatory, and must not meddle with the *Pyrus* now. If the house is merely to exclude the frost, and the back wall is not to be shaded, and you can give plenty of air, it need not be removed even in the autumn. The *Magnolia* will do very well if the heat is not often at night above 40° in winter, and you can give air and light enough.

FLOWER-GARDEN PLAN (*E. S.*).—We would prefer lining your beds instead of diamonding them. Our chief objections would be, that with the exceptions of 3 and 4, all the other five beds would have white or light edgings, and in No. 6 the *Pyrethrum* would smother the *Gazania*. Suppose you let 7 stop as it is; Flower of the Day, Brilliant, Purple King, and Ivy-leaf, white or variegated *Alyssum*, or *Cineraria maritima* as a broad edging. Then we would plant all the rest in pairs—opposite and crossed. Thus, 5 and 6 centered with *Pyrethrum* and *Heliotrope*, banded by purple *Petunia* or Purple King *Verbena* and edged with *Gazania*. Then 1 and 2 we would surround with *Mangliesii*, with just a strip of *Cerastium*, and 3 and 4, make a like, Tom Thumb, Christine, Lobbianum, and that would be infused with a string of purple or blue, as *Charlwoodii Verbena*, or *Lobelia speciosa*.

FLOWER-GARDEN PLAN (*S. L.*).—We are sorry that we cannot recommend a better rather dwarf Geranium than Brilliant, but Bijou, bounded by Cloth of Gold, would make a charming bed at 9; or you might make a centre of white, and two scarlets, and two oranges, all surrounded with an edging of purple, as Purple King *Verbena*. Your second border will be nice if you keep on *Campanula carpatia* to the autumn. In the first border *Calceolarias*, after *Perilla*, will be more telling than Geranium *Mangliesii*. We have no fault to find with your balance pair of fancy figures; but the whole would look better if 1 were in the same style as 9. You will get a good hint by referring to the plan given page 224, and that from “S. E. L.” in our next Number. In these you will perceive what we consider a test of good arrangement—that it is impossible to alter any figure in the group without destroying the effect of the whole. Now, you will perceive we could change any two of your figures into ovals, circles, or squares, &c., without making much difference to the plan as a whole; but of course it will look well when planted, and you have the best right to please yourself even as to the forms of the clumps.—R. F.

GULL (*Sutton*).—See what “G. A.” says to-day. One gull would be enough in your garden, and he would not object to a daily ration of raw garbage.

CULTURE OF TRICHOMANES RADICANS (*Boughspring*).—The fronds of your plant are grown in air too dry for them, and the becoming brown and dying is the result. We extract for your guidance the following from Johnson’s “British Ferns:”—“It may be successfully grown in a pot by first filling a middling-sized pot one-third full of finely-broken potsherds or sandstone, putting upon this a layer a little finer, and filling the remaining space with a compost of fine loam, silver sand, and finely-powdered sandstone in equal parts. This is to be pressed firmly together, and then the caudex or main root very carefully arranged upon the surface, fixing it by means of a few very small hooked pegs—the smaller in size and quantity the better. Then strew a little sand and powdered stone over the surface, just enough to cover and settle the roots. This being done, the whole is to receive a liberal watering from a very fine-rosed watering-pot, and left for a short time to settle. Place the pot in a saucer, the top of which is to be below the level of the top of the first layer of stone in the pot. This saucer is to be kept full of water, with a bell-glass turned over the pot, and to rest in the saucer of water. Place the whole in a warm greenhouse or stove, and by keeping the saucer filled with water success may be relied upon. Similar directions may be followed for cultivating this Fern upon a larger scale. Be careful always to keep the atmosphere moist and warm, which moisture will be secured by keeping the pan full of water.”

ANEMONES NOT FLOWERING WELL (*W. Reed*).—We have known Anemones do very well for four years without removal, but in general they are better when removed every two years, and either planted in a fresh place, or the soil in which they are grown exchanged for other soil. Generally they do very well without any manure, but they are benefited by liquid manure being applied while they are in a growing condition, or if the ground were covered with rotten dung while they are at rest it would benefit them much.

TOM THUMB GERANIUM (*T. Bolton*).—The flowering of Geraniums out of doors depends more on the character of the season after they are planted and the position they are in than on any treatment they receive beforehand. If the plants be good and can be turned out with good balls they will flower quickly if the season is a dry hot one. If, on the other hand, it is moist, they will likely run more to leaf in the early summer and not flower until late. Soil, however, has a little to do with this, and situation also.

CAMELLIA LEAVES SPOTTING (*A. K. H.*).—We cannot perceive any trace of insect on the leaves you have sent, but as you say you keep your plant in your drawing-room, may the discolouration not arise from the plant being so far from the light? or has it at any time been watered with anything pernicious, as salt in the water, or soda or any like chemical substance that might cause the disease? So many causes might give rise to the injury, that without being more fully acquainted with the particulars we are at a loss to define the real one.

SEEDLINGS FROM NEWTOWN PIPPIN APPLE (*H. P. B.*).—It is very unlikely that any of the seedlings from the pips of this Apple will come like the parent, but you may obtain one or more good useful kinds perhaps, as new varieties are obtained this way. It is, therefore, the best way to let the seedlings be transplanted out into the open ground by the middle of May, choosing damp weather for the job, and as they advance an experienced hand will be able to tell by the foliage which are Apples and which are crabs. The former may be made to bear sooner by their tops being taken off and grafted upon fruit-bearing trees. The others being only crabs may be used as such.

CINERARIA AND PRIMULA (*Southampton*).—We cannot undertake to recommend seedsmen; but we would say, if you really want good varieties of them, send to some one who advertises in our columns, and say you want the best they have, and would rather give an extra price to insure its being good. *Lapageria rosea* does not generally prosper from cuttings. At least we have never seen it do so.

TRANSPLANTED OLD APPLE TREES (*H. B.*).—In transplanting a young tree it is better not to cut it much down, because that reduces the chances of leaves forming in sufficient abundance to perform the functions of nature. This, however, is not the case with an older tree, for in the proportion between top and root there is an undue preponderance of the former, when it is taken into consideration that the roots are invariably injured more or less in the operation of transplanting. It is, therefore, better to cut down partially; otherwise thin the branches at once before the sap advances much, taking care to retain as many branches as will maintain the shape and character of the tree.

BAY TREES INJURED BY THE WINTER OF 1860-61 (*H. B.*).—If you do not object to the appearance the dead and dying shoots present, it is often as well to leave them on as to cut them away. If, however, they are very unsightly a part may be cut off at once, and it is to be hoped the ensuing season will restore them; if not, the worst had better be destroyed at once, and young ones planted, not in the same place unless the soil be exchanged. Cutting down evergreens entirely seldom answers; it is better at all times to leave a portion of the old foliage on, even if it be diseased. It serves in some respects to perform the functions required of it. Whatever cutting you make had better be done at once.

LYCOPodium LYALLI NOT PROSPERING (*Southampton*).—It is now the season for this class of plants resting, or rather it has lately been the season for that purpose, and if you had allowed it to occupy a place in a warm greenhouse and kept it neither too wet nor too dry, it would have been ready in a week or two to start a fresh growth. All herbaceous plants die down at one period or other of the year, unless their growth be kept up by unnatural excitement, which in the end brings on disease. No doubt but your plant will start and grow again by-and-by; but until it shows signs of doing so, keep it cool, and after it begins to grow increase the heat and you will find it come all right afterwards.

HARDY LARGE-FLOWERING CHRYSANTHEMUMS (—).—Some one, whose letter is mislaid, asked for a list suitable for growing far north, so we present the following:—Alfred Salter, Aregina, Auguste Mîc, Bixio, Bossuet, Caractacus, Cassy, Diadem, Duchess of Wellington, General Harding, General Slade, Golden Hermine, Jardin des Plantes, Little Harry, Lord Ranelagh, Madame Foggi, Madame Damage, Orange Brilliant, Plutus, Progne, Queen of England, Snowball, Striped Queen of England, Tribby, Yellow King, and Yellow Perfection.

VINES NOT DOING WELL (*A Subscriber*).—We fear that something else was wanted than removing the clay that overlaid the roots of your Vines on the border and against the house. It would have certainly been better to have taken up the Vines entirely and made a new border, and replanted them, or introduced fresh ones, for as you say the fruit last year was colourless and ill-flavoured, it was a pity to lose another season in the attempt to partially restore them by enticing the roots to the surface with a horsedung covering. Late as it now is, we would prefer destroying the Vines that are almost certain to be unsatisfactory, and remake the border and plant fresh ones. By having Vines with roots spread out in soil in a flat basket, and that basket kept in a suitable place under glass, growth will be going on, and you can plant basket and all when you have finished your border by the middle of May.

SEA-KALE UNDER AN APPLE TREE (*H. P. B.*).—If the roots of the Apple tree occupy the ground and the top overhang it, the Sea-kale will not be so good as when grown in the open ground. It will, however, succeed tolerably well if manure be liberally applied. See what has been said about Sea-kale in another part of our paper.

HYACINTHS IN GLASSES FLOWERING UNEVENLY (*F. W. B.*).—Most likely those bulbs which did not throw the flower-spoke above the collar were forced hard and early, when they are likely to do so; while those which did not open their flowers, but elongated the stem, must have either been from imperfectly-ripened bulbs, or perhaps grown in transparent glasses, exposing the roots to the action of the light: either of these causes would occasion the defect complained of.

PAINT FOR GREENHOUSES IN SMOKY TOWNS (*C. F. T.*).—Have the outsides painted a dark stone colour, and with the white paint inside have some Prussian blue mixed. The latter should be used wherever a greenhouse or conservatory may be situated; it gives a very pleasing tone to the colour.

AUSTRALIAN SEEDS (*Lex*).—They are all *Acacia* seeds, and require sowing in a light soil in a greenhouse, after being soaked for two hours in water you can just bear your finger in. *Wattle* is a colonial name applied to the *Acacias*, but which is the *Cape Wattle* we do not remember.

NAME OF SEED (*W. H.*).—The seed of *Abrus precatorius*.

NAMES OF PLANTS (*W. D.*).—1, No flowers; 2, *Acacia hispida*; 3, a *Chorozema*, without leaves; 4, *Tropaeolum tricolorum*; 5, *Azalea amena*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE POULTRY CLUB.

As a member of the Poultry Club, and one of the Honorary Secretaries thereof, I cannot allow the two condemnatory articles in your Journal of the two last weeks to pass unnoticed. From their tenor, I feel assured that the writer must be smarting under the conviction that the Club is formed to correct his and his brother Judge's errors of judgment, or that their decisions may be hereafter censured by the Club. It is well known to many exhibitors, that at many of our large Shows there have been most glaring mistakes, whether willfully or from not knowing the points I am not inclined to say. The gentlemen who have formed this Club have but one object in view—that of obtaining the honest and fair exhibition of poultry, and uniform judgment. And so far the success of the Poultry Club has been proved beyond what its promoters could have expected, numbering amongst its members, residents in England, Ireland, Scotland, and even Holland, including breeders of every known variety of poultry, many of them acknowledged judges, and "men of standing and position in society," who are prepared to act under the Poultry Club's rules. Time only will show whether the Club can accomplish the object aimed at. And even should it fail in doing so, the promoters will have the satisfaction of knowing that it has had a fair trial.

At the same time I must say I think the articles in question are premature; and it seems evident in predicting failure, that "the wish has been father to the thought."

In conclusion, I can only repeat that the Club will do all in its power to secure honest and uniform judging, without which poultry shows will share the fate which has been so assuredly anticipated for the Club in *THE JOURNAL OF HORTICULTURE AND COTTAGE GARDENER*. That such prediction may be doomed to disappointment, is the hearty wish of—EDWD. TUDMAN.

[We readily give insertion to Mr. Tudman's letter, for we have no object except the promotion of the interests of poultry exhibitors, and the success of poultry exhibitions; but we must express our regret that he has ascribed unworthy motives to those who have published in these pages opinions differing from his own. This is not the best nor the pleasantest way of attaining to the truth, for in this and in all other discussions, reasons should be weighed; what the reasoner's motives are, is perfectly immaterial.]

The only question for discussion is, Will the Poultry Club effect its objects? We think that it will not, and we have stated temperately why we so think, and we have that opinion sustained by the opinions of others well acquainted with poultry exhibitions. If wrong, no one will rejoice more than we shall over the success of the Poultry Club.—EDS.]

'MALAYS AT DEVIZES.

I DID not receive your Journal till late, and fully intended to reply to Mr. Fox's query, but it escaped my memory. If "better late than never," I would add a few words to your notes on the Malay. "*Chacun à son goût*," say our neighbours, and I do not doubt there are many who admire the Malay. Of those at Devizes, I admired Mr. Fox's as much as any, but for this reason—that, in my eyes they were less ugly than their prize and highly commended neighbours. Some young birds highly commended were those which provoked my "dotting;" they had not the brighter colours of the adults, which, to a casual observer, covers over defects. I would candidly say that, in my eyes, Mr. Fox's birds are too handsome.

I agree with your definition of the Malay; and if you do not think me too bold, I would add one or two points. The hackle of the Malay is peculiar to the breed; instead of the feathers, as in other poultry, getting longer as they approach the shoulders, they are nearly of the same length throughout, so that they fail to cover over the shoulders, and make the neck appear as if stuck on the body. I give you simply my own impressions. It is here, I fancy, and I beg pardon for saying so of so good a breeder, that Mr. Fox's birds fail. You say that the comb should be flattened down on the head, and I would add that the head should be broad, as well as overhanging the eyes. I agree with all your remarks about the scantiness of feather. Have you not, however, omitted a characteristic of the breed, especially of the featherless strains—that is, a peculiarly cool and defiant air? You may rattle your hand along the front of the pen, and your true Malay takes no notice of the affront, nor is he at all put out—indeed, had he a lip, I should expect to see it curl up; but that would be the only part of the body to move.

To turn to another subject. I am very glad to see that others have noticed the faults of omission and commission in the schedules of Worcester and Bath and West of England Shows. In both the duration of the Show is preposterous, and if it is unaltered, I hope breeders will come to the same determination as I have done—to keep my best birds at home.—Y. B. A. Z.

ACCRINGTON EXHIBITION OF POULTRY.

PROBABLY were those parties intimately conversant with poultry-breeding to attempt the selection of the most inappropriate time of all others to hold a public exhibition of this kind, a period of the year could not have more aptly suggested itself to their minds than the one adopted for the Meeting at Accrington—the first week in April. To exhibit their best birds at such a critical portion of the early breeding season would, it would be imagined, have daunted the spirits of even the most resolute and persevering; for now is the time in which the fondest expectations of all breeders beat high in anticipation of those chickens that are hoped to take all before them at our earliest Summer Chicken Shows. It is, of course, quite obvious no chicks of 1863 are as yet eligible for showing; whilst the stock-birds are so busily engaged, it taxes the resolution of their proprietors to the utmost to place so serious an interference to the production of early broods as that of exhibiting them at so important and anxious a season. To this particular Meeting, however, the time of holding the show appears rather that of an unavoidable necessity than the result of willing selection.

The Spring Fair at Accrington is always held on the first Thursday in April, and as their Cattle Show invariably takes place at this time, the poultry has become an adjunct to this meeting, only since the time that the universal desire to improve our breeds of domestic fowls has become so popular. Notwithstanding these serious drawbacks, as goodly a muster throughout the varied classes was got together as we have witnessed at any local meeting for years past. It is quite evident to all observers, that the Accrington Committee are as desirous as it is possible for men to be to insure permanent success to their undertaking, and both their collective and individual exertions are strained to the utmost to promote this desirable end; but they have not yet attained the experience of those who superintend our long-established societies. We will, therefore, just courteously suggest two points on which an altered arrangement would, without doubt, be most advisable. The one is, that the printed catalogues are openly sold about the streets for many hours previously to even the commencement of the arbitrations. This gives a great opening to the disaffected

(because disappointed) competitors, and throws open a good and sufficient cause of complaint as to the possibility of unfairness in the adjudications, should such be attempted. It has long been an established rule with all our principal committees, that no catalogue should be issued under any circumstances whatever until the arbitrations are finally settled. The other arrangement at Accrington, equally open to improvement is, that every person willing to pay the admission fee at the doors can be present even at a much earlier hour than that on which the Judges are themselves permitted to begin their duties, and afterwards narrowly follow such arbitrators step by step all through their adjudications, and that, too, within a distance of a few feet only. It is advanced in support of this last-named arrangement, that as the Show holds open only a single day no other plan can be adopted; but surely we contend that exhibitors who complain of the retention of their specimens for a few additional hours to meet this objection, by allowing the arbitrators to fulfil their duties calmly and with quiet unbroken deliberation, are not those on whom alone the success of poultry exhibitions depends. Having pointed out these essential points to improved management, we shall proceed to make a few remarks on the birds exhibited.

On entering, the eye of the visitor first rested on as excellent a *Game* class as need be wished for, every colour being equally eligible. A grand pen of Black Reds belonging to Mr. Fletcher, of Manchester, stood at the head of the prize list. They were not only perfect specimens, but were also shown in the condition for which this well-known exhibitor's birds are always proverbial. Mr. Grimshaw's Brown Reds were but little inferior, and obtained the second prize. We confess disappointment in the Single Game cock class, as the greater proportion were not shown in high condition. Brown Reds had here the advantage. In *Hamburgs* we never saw more reputable classes than both varieties of Spangled birds—they were a show in themselves; but in the Pencilled ones, whether Golden or Silver, we could only look back with regret when mentally comparing them with those exhibited in bygone years by Messrs. Archer, Chune, Tyler, and Worrall. We trust some enthusiastic breeder will strive to restore again to our meetings one of the most winning characteristics. The *Dorkings* were many of them good, but we especially noticed some three or four pens so grossly overfed as to have become alike quite useless, whether for exhibition or as stock-fowls. This lavish management invariably tends to the most annoying disappointment, for to any successful breeder it is well known poultry suffer less from paucity of food than over-petting. Captain Heaton's Grouse *Cochins* were very good, and the whole of the class of Black *Spanish* were a triumph of attentive management. *Game Bantams* were numerous and very good, a pen of capital Brown Reds here shown have seldom been surpassed. Some perfect *Polands* were also competitors in the extra class.

The *Turkeys* and *Ducks* were exceedingly good, and one solitary pen of *Geese* was well shown.

The last coop contained a singular addendum to a poultry show—viz., a Scotch Terrier bitch and puppies. The inquiry of visitors "what next?" was a natural one.

The day was beautifully fine: consequently the ground was constantly well filled, though, as the two hundred pens of poultry were arranged in one unbroken single line, no thronging took place. To excite the merriment of the company, the day's entertainment concluded with a spirited donkey race, with all its concomitant "ups and downs." The Committee were evidently trying all means to please every one, and were, beyond doubt, successful. With improved trade in this district, shows will most probably insure even greater popularity.

GAME (any colour).—First, J. Fletcher, Stoneclough, near Manchester. Second, N. Grimshaw, Pendle Forest, near Burnley. Highly Commended, C. W. Brierley, Oakenrod Terrace, Rochdale; N. Grimshaw; A. Hodgson, Church Row, Illingworth. Commended, J. Firth, Ellen's Grove, Halifax; E. Beldon, Park Cottage, Bradford. *Cock*.—First, J. Sunderland, jun., Colky Hall, Halifax. Second, A. Hampson, Bolton-le-Moors (Black Red). Highly Commended, R. Whittam, Mount Pleasant, near Burnley; N. Grimshaw; J. Firth. Commended, J. Sunderland, jun.; J. Fletcher; W. Ayrton.

HAMBURG (Golden-pencilled).—First, Miss E. Beldon, Park Cottage Bradford. Second, A. Nuttall, Newchurch, Rossendale. Highly Commended, J. Munn, Shawclough, near Manchester.

HAMBURG (Silver-pencilled).—First, E. Hindle, Woodnook, Accrington. Second, J. Dixon, North Park, Bradford. Highly Commended, C. Moore, Poulton-le-Fylde. Commended, E. Hindle.

HAMBURG (Golden-spangled).—First, Miss E. Beldon, Bradford. Second, J. Dixon, North Park, Bradford. Highly Commended, E. Whittaker, Edge-worth, Turton; N. Marlor, Denton, near Manchester.

HAMBURG (Silver-spangled).—First, J. Dixon, Bradford. Second, Miss

E. Beldon, Bradford. Highly Commended, J. Fielding, Newchurch, near Manchester; J. Patterson, Church, near Accrington. Commended, A. Bell, Burnley.

DORKING.—Prize, J. F. Newton, Kirby-in-Cleveland, Yorkshire (Coloured). Highly Commended, T. W. Hill, Woodlands, Heywood (Grey). Commended, T. W. Hill (Grey); J. Dixon, Bradford; E. Smith, Middleton, near Manchester (Grey).

COCHIN-CHINA.—Prize, Captain Heaton, Lower Broughton, Manchester. Highly Commended, F. M. Hindle, Bury New Road, Haslingden (Buff); Captain Heaton. Commended, F. M. Hindle (Buff); H. & J. Newton, Garforth, near Leeds; R. H. Nicholas, Malpas, Newport, Monmouth (Buff); C. W. Brierley, Oakenrod Terrace, Rochdale.

SPANISH (Black).—Prize, Miss E. Beldon, Bradford. Highly Commended, S. Robson, Brotherton, Yorkshire; J. Dixon, North Park, Bradford; E. Brown, Sheffield; E. Smith, Middleton, near Manchester.

BANTAM COCK (Game).—First, W. Lawrenson, Poulton-le-Fylde (Duck-wing). Second, T. Barnes, Accrington. Highly Commended, J. W. Morris, Rochdale (Black-breasted Red); J. Munn, Shawclough, Newchurch; W. O. Kenyon, Mossfield, Wavertree (Duckwing). Commended, C. W. Brierley; J. Munn; J. Crossland, jun., Wakefield.

BANTAMS (Game).—First, T. Barnes, Accrington. Second, J. Munn, Shawclough, Newchurch. Highly Commended, C. W. Brierley, Rochdale; J. Munn; J. Crossland, jun., Wakefield. Commended, E. Brown, Sheffield; R. H. Nicholas, Newport, Monmouth (Pile Game).

BANTAMS (Any other variety).—First, Miss E. Beldon, Bradford (Black). Second, J. Crossland, jun., Wakefield. Highly Commended, G. Ormerod, Accrington (White); J. Dixon, North Park, Bradford. Commended, C. W. Brierley, Rochdale; R. H. Nicholas, Monmouth (Chinese Silk).

ANY OTHER VARIETY.—First, E. Beldon, Bradford (Polands). Second, J. Dixon, Bradford (Polands). Highly Commended, T. W. Hill, Woodlands, Heywood (Crève Cœur); Mrs. M. Seamons, Hartwell, Aylesbury (Brahma Pootra); H. & G. Newton, Garforth (Black Hamburgs); H. Lacy, Underbank, Eastwood (Dark-pencilled Brahmas); R. H. Nicholas, Newport, Monmouth (Black Hamburgs). Commended, J. Hargreaves, Broad Oak (Brahma Pootra); A. Lord, Blackburn (Cuckoo Creels).

TURKEYS.—Prize, J. Dixon, Bradford. Highly Commended, J. Cunningham, Snigbrook, Blackburn. Commended, T. Bury, Church Kirk.

DUCKS (Aylesbury).—First, H. Kenyon, Fern Grove, near Accrington. Second, Mrs. M. Seamons, Hartwell, Aylesbury.

DUCKS (Rouen).—First, Miss E. Beldon, Bradford. Second, J. Houliker, Richmond Terrace, Blackburn. Highly Commended, E. Leach, Rochdale. Commended, J. Dixon, Bradford.

GEESSE.—Prize, J. Houliker, jun., Blackburn.

Mr. Edward Hewitt, of Eden Cottage, Sparkbrook, officiated as the Judge.

"B. & W.'s" APIARY.

(Continued from page 666.)

I HAVE unfortunately to record the total failure of my last autumn's operations in my apiary. I refer to my second attempt to Italianise it, by destroying the queens of five stocks, and compelling the bees to rear queens artificially in their place out of pure Italian brood. The young queens, indeed, were duly hatched, all five of them, several of them beautifully marked; but one of them died of starvation (I am ashamed to tell it), a second died of dysentery in January last in spite of all attempts to save the stock, and the three survivors of this terrible bee-winter have done nothing hitherto but breed drones. This I feared would be the case, owing to the great scarcity of drones in my apiary last August. The fact is—none of them, of course, were impregnated. It was only last week, on the 21st, that I was able to assure myself of the truth by actual inspection of two of these hives, although I had suspected it by seeing several small drones alive and dead about the garden.

It may interest your readers to know what I have done, and what I purpose doing with these hives, with a view to saving them if I can; but let me first give the arrangement of my surviving stock at the time I recommenced operations last week.

BEE-HOUSE.

A.	B.	C.
Pure Italian queen (weakish but active).	Italian drone-breeding queen (weak).	Italian drone-breeding queen (weak).
D.	E.	F.
Hybrid Italian queen (strong).	Hybrid stock died in January. Strong stock from garden now in its place.—("J." at p. 666.)	Italian drone-breeding queen (weakish).

GARDEN.

G.	H.	I.	K.
Dead.	Strong.	Weak.	Given away.

I began then by hunting for and destroying the drone-breeding queen of B. I then took a comb with brood of all ages out of A (pure Italian), and inserted it in B in place of an empty comb, taking care not to disturb the combs containing the few drone-grubs in B, which I now look upon as the *spes gregis*. The queen of C was then caught and killed, and all the bees turned adrift to find a home where they could. My hope was that

finding their own home shut against them they would have fraternised with their next neighbours of B, and so strengthened that hive. Not so, however; most of them entered E, already strong, on the shelf below them, and some were admitted into F. A few were rejected and killed, but not many. What drone-brood was formed in C was also inserted into B, and I am rejoiced to see that it has been tended with care.

Now as to future plans. In Easter week, by which time I expect the young queen of B to be hatched, and the other hives to have gained strength, I intend to proceed as follows:—1st, make a swarm of D by driving it into a box well stored with comb and food; 2nd, place D, when cleared of its adult population, in the room of A, after driving or shifting into D the Italian queen and population of A; 3rd, put A with its Italian brood alone in place of E, setting F over it after first catching and destroying its drone-breeding queen; 4th, make a swarm of E by driving into a box well stored with comb, as in the case of D above; 5th, place E with its brood-comb under B. Here are five distinct operations tending to equalise my stocks in point of population, and to preserve two out of three of the drone-breeding stocks which otherwise would have perished, by supplying them first with the means of rearing fertile queens, and then with an increased population to work with. In this way, too, I shall turn the misfortune of drone-breeding to some profit. I may mention that several of the drones which I examined were well-marked Italians. I also had a good view of the queen of A, which is a most beautiful specimen of her race, and large and vigorous also. This plan of mine, as detailed above, courts the criticism of the "DEVONSHIRE BEE-KEEPER." He will at least allow it to be an ingenious one. Can he suggest an improvement upon it? if so, I shall be glad to hear from him.

I cannot conclude without remarking upon the extraordinary condition of the bees in this country. Deserted apiaries are to be seen everywhere. I believe that nine-tenths or more of our English bees have perished this winter or the previous autumn. I venture to predict (and I was a true prophet last May), a fine summer for honey, if only we have a dry and rather cold six weeks before us.—B. & W.

[Whilst disclaiming all pretensions to criticise the programme of so accomplished an apiarian as "B. & W.," I can fully corroborate what he has stated with regard to the difficulty—in fact, I may say the impossibility, of getting late-bred queens impregnated last year. Nearly all of mine were slaughtered by their own bees, whilst the only two that survived turned out drone-breeders in the spring. This phenomenon must probably be attributed to continued low temperature rather than the paucity of the male sex. Dzierzon places the temperature required for a successful wedding flight at above 75°, and I am disposed to think that not less than 70° to 75° will suffice. How few days were there last year during which the thermometer stood so high as this in the open air! In one of my own hives a great number of drones were in existence until quite late in the autumn, when they were expelled by the workers in the ordinary way; and yet the young queen of this colony is at the present moment incapable of breeding aught else than drones. I purpose keeping her alive, if possible, for the sake of her male offspring, recruiting the worker population by the insertion from time to time of a sealed brood-comb: this course is, in fact, substantially the same as is proposed by "B. & W.," with respect to the drone-breeder in hive B.

In conclusion I may add, that most heartily do I wish my esteemed apiarian friend a happy issue out of all his difficulties; and if I can in any way aid in the solution of the "Italian question," the doing so will afford much pleasure to—A DEVONSHIRE BEE-KEEPER.]

SPRING PASTURAGE FOR BEES.

ON a visit we recently paid to the Sawbridgeworth Nurseries, we saw a large quarter of *Salix caprea* (as we thought) in full bloom, forming a complete sheet of golden catkins, and peopled with myriads of bees. The day was bright—one of those lovely summery spring days we have had so many of all this season, and the lively hum of the busy throng made music in the air. This was early in March, and there were the bees evidently revelling in what appeared to be an unusually rich store at that season of the year. What struck us particularly was the great profusion of bloom on trees so small. Some of them were not more than

bushes 2 to 3 feet high, and every young shoot was a dense spike of catkins. We had always regarded the *Salix caprea* as a large tree when it bloomed; and our curiosity being excited by seeing so much on trees so small, we appealed to Mr. Rivers, who informed us that this was a variety of *Salix caprea*, which possessed that peculiar property of flowering when very small and young. He procured it some years ago from the north of England, and has hitherto used it as a stock for grafting the American Weeping Willow upon. What a treasure this would be to bee-keepers, who might plant a few in proximity to their apiaries, or in shrubberies where it would furnish abundant pasture to bees at a season when they are frequently enticed out by bright weather when there is really very little or nothing for them to pasture upon.

BEES IN THE NEW FOREST.—A great quantity of Mead—*medu*—is still made here, and it is sold at much the same value as with the Old-English, being three or four times the price of common beer, with which it is often drunk. The drones are here named "the big bees." Bees are never said to swarm, but "to play." The caps of straw put over the "bee-pots" to keep them from wet, are called "bee-hackles," and "bee-hakes." About the honeycombs or "workings," as they are commonly called, there is this rhyme:—

"Sieve upon herder,
One upon the other;
Holes upon both sides,
Not all the way, though;
What may it be? See if you know."

The entrance to the hive is called the "tee-hole." An eke for raising the hive and giving more room is called "the rear."—(*Wise's New Forest.*)

OUR LETTER BOX.

POULTRY DYING SUDDENLY (*J. Price*).—You should have told us the symptoms. The appearance indicates long-continued constipation and consequent inflammation of the bowels; but the same appearance may have arisen from the birds eating something poisonous. If the birds are constipated give each a dessert-spoonful of castor oil, and do not feed exclusively on barley. Soft food, such as barleymeal mixed with mashed boiled potatoes, should be given once a-day.

BANTAMS (*Novice*).—We believe you have some Bantams bred between Game and common ones. You will probably find them very good sitters, and useful fowls for all purposes.

DIARRHŒA IN BANTAMS (*O. D.*).—We do not believe the lump you speak of in the Bantam's abdomen is painful. Fomentation with hot water is beneficial, but if it does not increase we advise you to let it alone. The lump is sometimes a cheesy deposit under the skin, and in that case it is only necessary to make a slight incision, and to squeeze the back of it, when it will slip out. This must be ascertained; because if it be, as they are sometimes, a blood-tumour, cutting is worse than useless.

POINTS IN TURBITS (*Inquirer*).—The most important points in Turbits are the following:—They should be small and neat, large coarse birds being particularly objectionable. The head in a good Turbit is peculiar, being flat and somewhat frog-like; the beak should be short, but not turned down like the beak of an Owl or Barb. The shoulders should be without white splashes, and of a sound uniform colour, whether red, black, or yellow; if silver or blue, with the black bars well and distinctly marked; the less colour on the thighs the better, though it is very difficult to breed them without any; the entire plumage of the body, flight, and tail feathers pure white. With regard to the turn-crown, some prefer a mere point of recurved feathers, others a broad shell; and prizes have been awarded by good judges to plain-headed birds. It is indispensable, however, that the pair must match accurately. As a rule we should think that the turn-crowns would beat the plain-headed under all judges, other things being equal. It is an additional property, and one of some importance.

WINDOW AVIARY (*H. B.*).—The window is in a very good aspect for an aviary, and the size you mention would hold from fifteen to twenty small birds. The following would stand the cold and agree very sociably together—viz., the Goldfinch, Chaffinch, Bramble Finch, Bullfinch, Grey Linnet, and Redpoll, and as the season advances the Canary, Java Sparrow, and Averdine might be added. A small fir tree in the centre would add to the appearance, and the birds would enjoy it.

DRIVING BEES (*Sutton*).—If you place a strong stock upon an empty box, and compel the bees to work through the latter, they will ultimately take possession of it, and when they have adopted it as their breeding-place, the original hive may be removed. No precise period of time can be named for the completion of the transfer, which is open to the double objection—that if successful, no swarm can be expected this summer, and so great a proportion of drone-comb is apt to be built under these circumstances as injuriously to affect the future prosperity of the colony. After driving bees into a straw hive, you may readily transfer them into a box, by knocking the cluster out on a cloth, and standing the box over them, supported on wedges or a couple of sticks an inch thick. As soon as all the bees have ascended they should be put in the place they are intended permanently to occupy. Whilst replying to your inquiries, we should strongly advise you to eschew either of these operations and trust to natural swarming.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 57.7° and 36.1° respectively. The greatest heat, 77°, occurred on the 19th, in 1854; and the lowest cold, 20°, on the 16th, in 1847, and 19th in 1852. During the period 154 days were fine, and on 98 rain fell.

WINTER-FLOWERING ORCHIDS.

WITHIN the last two or three years I have been repeatedly told that there was a fine well-grown collection of my favourite tribe of plants cultivated at Pendlebury House, near Manchester, the residence of J. A. Turner, Esq., M.P.; and as I was desirous to inform new beginners what species bloom at a season of the year when Flora's gifts are few and far between, I made up my mind to see the collection referred to above, surmising that I should find some still in flower. Accordingly on the 27th of last month I took advantage of an omnibus to Pendleton, which is two miles from the centre of Manchester, and Pendlebury is nearly two miles further on the road to Bolton.

The country thereabouts is undulating but gradually rising. I found the house pleasantly situated on an eminence, embosomed amongst fine trees, chiefly Beech, showing that the smoke of Manchester, and the tall chimneys of its factories, had not destroyed all the trees in that district. In fact, many gentlemen's seats I observed were surrounded by apparently healthy, large forest trees; whilst on the side (south-east) where I live, the trees are mostly scraggy starved specimens, owing to the subsoil being a strong, wet clay, and the top soil thin and poor. Indeed, any observing person may judge of the soil and subsoil of any district of country he passes through, by noting the state of the hedges and trees there growing.

A mere list of the Orchids at Pendlebury House would not occupy much space, and would not convey much information; so I will add a brief description of each, especially such as are not common, and consequently are not generally known.

Ansellia africana is not rare, but here is a truly noble specimen with strong pseudo-bulbs 5 feet high, and so many that the plant measured as much through.

Brassavola glauca.—This was growing on a large round block. There were two varieties, one much larger and handsomer than the old variety. The flowers of both are large and striking.

Cattleya Warczewiczii.—Rare. A delicate flower; large and beautiful rosy purple sepals; lip a deep yellow, large spot in the centre margined with bluish.

Ceologyne ocellata.—Medium size; inside distinctly edged dark, spotted with light colour.

Cypripedium Fairrianum.—A beautiful dwarf species, with pure white sepals, and petals richly striped with dark maroon; lip or slipper greenish-yellow, veined with dark coloured lines. This a real gem among Lady's Slippers.

Cyrtorchilum maculatum.—A good old species, free-flowering and very handsome.

No. 107.—VOL. IV., NEW SERIES.

Dendrobium nobile.—Too well known to need describing. A splendid specimen 4 feet by 4. Very densely flowered.

Calanthe vestita tardiflora.—Pure white sepals and lip, the centre of the latter has a spot of dark maroon. The flowers are more densely placed on the flower-stem, and are of a more compact form. It flowers at least two months later than the species, and so far is a desirable variety.

Dendrochilum glumaceum.—Small flowers, of a straw colour. They are numerous and densely set on a drooping panicle. There were twelve spikes on the plant. Though not a showy species, it is very desirable on account of its elegant habit.

Epidendrum aurantiacum.—A species with golden flowers. Not rare.

Epidendrum verrucosum major.—A fine variety, with dark flowers spotted with white.

Ionopsis paniculata.—A pretty little white-flowered species. Well worth growing.

Oncidium Cavendishianum.—One of the large-leaved section of Oncids, with large bright orange flowers on a lofty branching flower-stem. Handsome and showy, and easily cultivated.

Oncidium leucocochilum.—A handsome well-known species, flowering almost all the year round.

Odontoglossum bicktoniense.—A handsome species. Useful as a winter-flowerer.

Phalenopsis grandiflora.—This is a beautiful well-known species, with large moth-shaped flowers, blooming when strong nine months out of the twelve.

Phalenopsis Schilleriana.—A new and rare species, with medium-sized flowers of a delicate rose colour. The flowers are handsome, and, in addition, the leaves are beautifully variegated. There were two plants here: one had made a new leaf nearly 9 inches long. I valued the two plants at fifty guineas, but was informed that a nurseryman had thirty-five guineas for the larger plant.

Vanda cristata.—A noble plant, with large, rich, crested flowers.

Zygopetalum hirsutum.—This is a pretty dwarf species, with a large hairy lip of a purplish colour.

The above list proves that an Orchid-house may be gay with flowers even in the dead of winter, though in this district very little of what we understand by winter weather has been experienced; as a proof of which, I saw the other day a Pear tree and also a Plum and an Apricot tree with fully expanded blossoms.

This collection of Orchids is extremely well grown. The gardener, Mr. Tate, is an Exeter man, and fully understands his business. He has adopted cocoa-nut fibre dust as one material to mix among the usual compost. He pointed out to me how the *Cattleyas* were rooting amongst it. In all my experience I never saw such a quantity of young, healthy, strong roots pushing freely out and around every pseudo-bulb. I said if my friend Beaton saw them he would be in ecstasies. No man has done nearly so much as he has to bring this

No. 759.—VOL. XXIX., OLD SERIES.

valuable substance into repute as an addition to our composts.

Let all Orchid-growers throughout this empire procure it as soon as possible, and mix it among sphagnum moss in the proportion of two parts moss and one part fibre. I feel so confident of its usefulness, that if I had a large or a small collection of Orchids under my care I would immediately use the fibre in preference to any other substance. I think the fibre would not do by itself. It would be too open and dry too quickly, especially during the warmer months of the year. I conclude the paper by mentioning some of the rarer plants in Mr. Turner's collection.

Cattleya Leopoldi.—Several plants large and healthy. Mr. Tate told me almost every plant was a different variety.

Cattleya citrina.—This species, which is somewhat difficult to grow, is well done here. Each plant is fixed to the under side of the block.

Dendrobium formosum giganteum.—The flowers of this rare variety are double the size of the original species.

Dendrobium aggregatum major.—This variety has flowers of much larger size than the species. It is showing eighteen spikes of flowers, and is grown in a pot.

Lælia Turneri.—A remarkable species, with stems 2 feet high. It belongs to the two-leaved section. Each leaf is a foot long, and 3 inches wide.

Cattleya lobata.—This is said to be a shy flowerer, but here it flowers freely every year.

Lælia wanhina.—An orange-coloured *Lælia*, much superior to *L. cinnabarina*.

Cypripedium hirsutissimum.—A fine specimen of this rare and beautiful species.

Cypripedium Hookeri.—A plant that ranks under the class of Beautiful-foliaged plants; the leaves are dark green, spotted and barred with pure white.

Angracum superbum.—A plant 5 feet high, with leaves 2 feet long, set on each side of the stem as regularly as the bones from the spine of a herring.

Ardis cænobita.—A fine specimen of this rare species.

Erides odoratum purpurascens.—A distinct variety with more and larger purple spots on each sepal, petal, and lip. A good plant.

Vanda teres.—A large bushy plant 6 feet high, and 5 feet through. Mr. Tate says it is a distinct sort known as East's variety. Flowers freely annually.

Epidendrum bicornutum.—There I noted a large healthy plant of this, which is one difficult to grow. It is cultivated in a pot in the usual compost, only it is raised high in the centre.

I might have extended this list considerably, but I fear I have trespassed already too much on your valuable space. I must close by saying that this is the best-grown collection of Orchids I have seen for many years. They are in houses of the usual form—that is, span-roofed, and they are so arranged that you can step out of India into America merely by passing through a glass door. Even the potting-place is glazed and connected with the houses, so that in manipulating the plants they are never exposed to ungenial weather at any season of the year.

T. APPLEY.

IN MEMORIAM.

THE REV. GEORGE JEANS, VICAR OF ALFORD.

RARELY has my humble pen undertaken a more melancholy task (so selfishly, alas! do we regard the ways of our Heavenly Father), than in conveying to many who have benefited by his remarks, or who have known his name as intimately connected with gardening pursuits, the news that my valued friend whose name heads this notice has gone from amongst us. How little did I think, when alluding to him in the notice of the Warden of Winchester's garden as the friend who had told me to visit Mr. Weaver, that I should so soon have to number him amongst those whom one had known rather than as one still present with us.

It is now some years since that the cause of one of our great religious societies in which I was interested led me to visit Alford as its advocate. I was then a stranger to the Vicar, but had been assured that I should meet with a hearty welcome. In this I found that my information had been correct; my work's sake was sufficient to insure me that.

On the following morning, taking, as is my wont, an early stroll, I espied in the garden a frame of Auriculas then coming

into bloom. This soon led us to touch upon another subject on which we had common sympathies. And as each recurring year led me to Alford, and other opportunities of meeting one another were afforded us, our acquaintance ripened into friendship; and I have for many years esteemed it a great privilege to number amongst my friends one who was so fine a type of an English gentleman, a ripe scholar, and a Christian pastor, as my late revered friend.

Distinguished in early life, when scientific pursuits were not so much in vogue as they are now, for his attention to philosophical inquiries, astronomy (on which he published an excellent and most readable treatise), geology, chemistry, &c., found in him one who appreciated their value and could bring them practically to bear. These studies he never allowed to pass out of sight. He eagerly read all that was really valuable in connection with them; and no way led astray by injurious theories which had no foundation better than a "hypothesis," he was yet by no means opposed to whatever new light advanced knowledge on these subjects from time to time produced. He was not one of those who believed that God's words and God's works are contradictory. He did not consider it derogatory to Science to regard her as the handmaid and not the mistress of Revelation; and works of a contrary tendency were regarded by him as hurtful to the cause of truth as well as of science.

His transit instrument on the lawn, his geological specimens, and lectures delivered only last year, clearly showed that these earlier pursuits had still their charm for him; while his conversation on these and kindred subjects showed how fresh were still his thoughts and feelings. But it is as connected with floriculture that his name will be especially regarded by the readers of THE JOURNAL OF HORTICULTURE. For many years under his *nom de plume* of "Iota," latterly, since his friend Mr. Edward Beck's death, exchanged for his real signature, he contributed largely to various gardening publications. His philosophical mind could only view even floriculture in this aspect; and I have always felt that it was something for florists to be able to number amongst them one who did not think flowers, despised by many scientific persons, as unworthy of his notice. When Mr. Beck in 1848, disliking the tone that then pervaded gardening literature, determined on starting a periodical in which a better spirit should prevail, he summoned to his aid, for the columns of *The Florist*, the Vicar of Alford; and I may be excused for referring to a notice in the volume of that work for 1861, prefixed to a touching notice, written at my request, of his friend's death—all the more so as he has so soon followed him:—"It would ill become us to add anything to the very interesting account that he has given of the life and character of his deceased friend; but we may say that which his modesty forbids him saying himself—that the pages of the 'Florist' in those days to which he refers owed a great portion of their attractiveness to his own writing. Page after page bears the evidence of his clear and graphic pen, even where his signature appears not."

While the wide field of information over which my friend's discursive fancy could roam, enabled him to grapple with many subjects connected with gardening, it was of the Auricula he chiefly delighted to write. It was his pet, *par excellence*, and a collection unsurpassed for variety testified to the energy with which its cultivation was carried on. His judgment was sound; for as a thorough florist he admitted no restriction of rules, ruthlessly consigning to the border flowers unworthy of the stage; and when admitting varieties that were not excellent in their character to a place in his frames, assigning as his reason the real cause of his doing so. In the proposition of a National Auricula Society he was deeply interested, and, when I first proposed it, was one of the first to welcome it by his promised aid; and when the project was taken up by Mr. Douglas and carried out, he gave his earnest support. The last paper I think that he wrote was a short one for the *Floral Magazine*, in which he alluded to the forthcoming Exhibition at York, and expressed his wishes for its success. Of late years he had more frequently contributed to other periodicals; and some most reliable notes on his favourite flower will be considered by connoisseurs as a favourite authority.

He will be, indeed, a great loss to the gardening community, and will be long remembered as one of those who have given a healthy stimulus to floriculture. And I cannot forbear saying, that when, some years ago, through the carelessness of an old man whom I employed, my embryo collection was lost, and I had determined to abandon their growth, it was he who urged me

not to do so; and by his own liberality and that of others whom he interested I was enabled to begin again; and whenever he could do so he always was ready to add to it some choice sort of which he had a small piece to spare, for a more liberal florist I never knew.

I am sure that I shall be excused if I add a few words of what I knew of him as a Christian and a pastor. Endued with powers of mind of no common order, it was his delight ever to preach the simple Gospel of the Lord Jesus. His heart was large; and whenever he recognised a love to the Saviour, there he was ready to acknowledge a brother. Placed in a parish of which the emoluments were a mere nothing, and where neglect had long prevailed, he endeavoured to raise the standard of religion and morals; and having built a parsonage, was engaged in plans for the restoration of his church when death put an end to them all. His life was all in accord with his teaching; and that best of all teaching—example—in him was thoroughly carried out. Over all that concerned his domestic life I must draw a veil. It will readily be believed that one who so thoroughly lived the life of a true Christian would shine in the home circle; and as a husband, father, or brother, there are those left behind who with tears can bear witness to him in all these; while as a friend, there are many who will be ready to feel that his loss cannot well be replaced.

I little thought, when writing to me a few weeks ago, this passage occurred—"I never worked harder in my life, but it will not be so for long," how it was to come true in another way than he himself anticipated. But "marvellous are Thy ways, O King of Saints!" I may use his own words in allusion to Mr. Beck:—"It was floriculture that brought us together, but the Gospel of Christ cemented that friendship." As he was a man of prayer, we may well believe that He who answers prayer will watch over his dear ones left behind, and that the remembrance of his loving Christian life will cheer them on in their future journey.—D., *Deal*.

TREE MIGNONETTE.

THE following minutiae, it is hoped, will meet the case of others as well as that of "A SUBSCRIBER," who has been "trying in vain to raise such trees."

In March or April, better the middle of the former, select rather more of nice clean 60-sized pots than you wish for specimens of Mignonette trees, to make allowance for a few not turning out so well as the rest. Drain these pots, and fill them to within a quarter of an inch of the rims with rich light loam, such as might be made with two parts of brown hazelly loam, one part of very decomposed sweet leaf mould, half a part of heath soil, and less than half a part of silver sand; then drop a few seeds—say four—in the centre of each pot, covering them up nicely. The common Mignonette answers very well. The large-flowering Mignonette will produce stronger stems and larger trusses; but we think the old common sort blooms in general more profusely—but either kind will bloom abundantly if well treated. When sown the best place for the pots is the back of a Cucumber or Melon bed, where the pots can be plunged, and air given to the young plants as soon as they appear. In such circumstances they will not be long before they make their appearance.

As soon as the plants are half an inch in height examine those in each pot narrowly, and select the one that seems the most bold and luxuriant, either pulling the others out, or, what is better, cutting their stems below the surface with the point of a penknife, so as not to injure the roots of the one plant left in each pot. Were it not for this power of selection, and the certainty of getting a good plant, it would be as well to sow only one good seed in a pot at once. By the time the plant is an inch in height, any side shoot that offers to come should be disbudded, picking it out, but allowing the leaf next the stem to remain. When the centre shoot is from 2 to 3 inches in length, a little twig should be set against it, and the little stem tied to it to encourage it to mount, nipping out every side shoot that shows, but allowing the leaf to remain, as that adds strength to the stem, and, besides, gives it a more furnished appearance. The little twig stake should be 1 or 1½ inch from the stem; and in the process of growth, as a larger and stouter stake becomes necessary, the lesser stake should be carefully taken out and the larger one inserted in the same hole, so as to run as little risk as possible of injuring the roots.

As soon as these little pots are getting full of roots, and before the roots meet the sides of the pot, shift each plant into a large 48-sized, and plunge the pot, and keep training the main stem and disbudding all side shoots as before. As soon as that pot is filled, shift into a 32-sized pot, and let the soil be a little rougher, and give a little bottom heat as before. If the main shoot go on without showing flower it will be all smooth sailing, the disbudding of all side shoots being the principal thing; but if the leading shoot show bloom it must be nipped off, and then the best-placed shoot that comes you must train on as a continuation of the first stem; and sometimes if you want a tall stem, you may have to do this several times before you obtain the desired height. Whatever the height of the stem before the head forms, be it 1 foot, or a couple of feet or more, no flowers should be allowed to remain until the stem is as high as desirable; nor even then until the head of the tree is pretty well formed.

When the 32-sized pot is about full of roots, I prefer placing the plants in their flowering-pots, and a pot of 12 inches in diameter and depth will support a very nice specimen. In this last potting—and the pot may be larger if an extra-sized specimen is desirable—the drainage must be well attended to, and the soil chosen of a more lumpy character, so as to avoid anything like stagnant water; and to help this still more, a few additional pieces of fibry heath soil, and some bits of charcoal the size of beans, may with advantage be added to the compost. This rough material should be squeezed together pretty tight, and the surface covered all over with fine material to the depth at the sides of at least half an inch, which will prevent the air entering the soil too freely. In all such shiftings, care must be taken that the soil in the pot is moist, but not deluged, before shifting; and this will be best secured by watering thoroughly four hours or so before repotting. After this final repotting, if the pots can be partly plunged in a mild heat for a fortnight or so, it will be all in their favour; but by July they will stand well in any pit or house where they can receive moderate attention. In such places the plants will do better when the pots stand on a shelf, or on the bottom of another pot reversed; as when the pots stand on the ground the drainage is apt to be injured, and the exhalations that rise from such wet ground are not at all in their favour.

Until the head is formed it is advisable to have a frill of leaves all along the stem, but no side shoots; that, as above stated, not only furnishes clothing, but gives strength to the stem. As the head swells in diameter, the leaves on the stem will most likely be robbed, and will then fall off. In general it would be best to have the shortest-stemmed plants for winter-blooming, and the tallest for spring-blooming, as the former may be supposed to perfect their heads sooner. In both cases the treatment is much the same, as the plants should not only be kept airy, but in a temperature of from 45° to 48° or 50° in winter, with a rise from sunshine.

In training, many contrivances may be adopted, with wire, &c., for supports. I will describe a very simple mode. I will suppose that the stem is high enough for the lower branches of the future tree. Well, the plant is held carefully, the old temporary stake removed, and a stout one, fully half an inch in diameter, is inserted firmly in the same place, and as much higher above the lower branches as we wish the point of the tree to be—say some 15 inches above the lower branches. Well, after tying the stem securely to the stake, the next operation is to make that secure in the pot, so as to carry the weight of the future head; and no simpler plan exists than taking two pieces of wire at right angles from the stake across the rim of the pot, and fastening them there. Then two holes at right angles a little apart from each other about the level of the lower branches—say 18 inches from the pot—will do for putting through two stout wires like the spokes of a wheel. A wire fastened to the points will form the circumference, and lesser wires between will furnish the means for tying the branches. Six or 8 inches higher up other two wires should be inserted for a smaller circle, and thus the orbicular pyramidal head may be easily secured. There must be regular stopping and training, and nipping-off of all flower-buds until the head is formed, and then each shoot may bloom as it likes.

When the head is forming, and also when in bloom, clear manure water, and not too strong, may be pretty freely used, except in very dark weather in winter. To keep the plants long healthy and producing abundance of bloom, no bloom should be allowed to remain when it is old or showing signs of seeding. One truss with seeds swelling will injure the plant more than a

score of half-opened trusses. This continued pruning-away of every flower when past its best, even though the point should be fresh, is the secret for keeping plants long in health. By such means we have seen a plant of common Mignonette grown in the common way, or hanging over the pot, very good after it had been in the same pot seven years. When these tree Mignonette plants are a full mass of bloom at one time, this thinning of flowers must be done freely if the plant is to keep on long afterwards. By this free thinning, stopping and training in summer, and fresh surfacings of good soil, the same plant will continue for years; but there is so much trouble in keeping the soil in a healthy state in such large pots through the winter, that generally it will be the best plan to sow and grow one season for blooming during the earliest part of the next.

When I was fond of such plants I used to grow some as pyramids—that is, the base of the cone on a level with and falling over the rim of the pot, and the plant gradually lessening in width to the apex. Such plants from 15 to 20 and 2½ inches in height are very pretty. The main features of management are the same, with the exception of securing the necessary and right-placed side shoots; and to produce them the stem had sometimes to be stopped, as there was little risk of that not getting up.

The above remarks, however, apply only to what are generally called tree Mignonette plants. There is but one little point concerning them which I have overlooked, and that is carefulness in watering if the last shift should be a large one. In that case only the new soil in proximity with the ball and the ball itself should be watered, and the bulk of the new soil at the sides of the pot should not be deluged until the roots are working in it. This rule applies to all large shifts, as otherwise the soil is apt to become soured; and if so, the Mignonette trees will not flourish.

R. FISH.

THE FLAVOUR OF FRUIT.

In writing of the Warden of Winchester's garden, "D." of Deal, tells us that Mr. Weaver, "like most practical men, has a contempt for fruit trees in pots," and that "the fruit is poor in comparison with that grown on trees planted out." When will there be an end of these baseless opinions given by *soi disant* "practical men?" Ah! when?

I have a great respect for the abilities of Mr. Weaver, and for his character generally; but I cannot resist telling him that I am also a practical man, and that I know his opinion as given above has no foundation whatever. Why is "Mr. Rivers, of Sawbridgeworth," excepted, when writing of failures in orchard-houses? There are hundreds of gardeners much more clever, practically, than he is, and able to do what he does.

He has, however, one quality which carries, and has carried, Englishmen through many ill-organised plans and many scrapes, and made them triumphant in so many quarters of the world—the most dogged perseverance; and if the principle of any mode of culture is sound, perseverance must in the end triumph. Thus it is, that in spite of the prejudices of many men, orchard-house culture is annually spreading and triumphing.

I am quite aware that I need not tell such men as Mr. Weaver that the flavour of fruit, barring extreme sunless seasons, is entirely under the control of the gardener. A clever man can command flavour; a dull man, when he finds his fruit flavourless, makes idle excuses, which should never be listened to.

During last summer I had numerous French fruit-growers visiting me, and they were all struck with the (to them) new idea—the culture of Peach trees in pots, and, I may add, equally delighted; for although in the greater portion of France Peaches do not require the summer climate of the orchard-house to ripen their fruit, it was the immunity from spring frosts, often so destructive in their country, that delighted my French friends. Well, they were, of course, anxious to taste the fruit. I remember gathering some fine specimens of the Noblesse Peach from a tree in a pot, which they declared *exquisite*, and equal, if not superior, both in size and flavour to any they had ever eaten in France. I had, in truth, commanded them, as it were, to be good, and they were good—and why so? Because they had been thinned severely. This is the control I have alluded to.

If a tree trained to a wall be allowed to ripen—say ten dozen of fruit, when five or six dozen only should have been left, they, although they may be of a fair size and colour, suffer in flavour to an extent scarcely credible. It is the same with potted trees;

they are in most seasons, and more particularly this season, crowded with fruit. Now, if a Peach tree five or six years old be suffered to bring to maturity five or six dozen of fruit when only three dozen should be left to ripen, their flavour will be most inferior; and then men who when prejudiced look only at the surface of things, cry out, "How can you expect good fruit from trees in pots?" Such are thy ways, O Prejudice!—the peculiar attribute of the cultivators of the soil, and I fear also of some of the cultivators of the arts and sciences. It is like "the old man of the sea,"—it clings to us, it will not be shaken off. In the case of Sinbad the more he was shaken the closer he clung to his victims, and nearly choked them by entwining his legs round their "throats." In like manner does prejudice too often strangle the working of our brains.

To return to our fruit. How often has the gardener had occasion to complain of his Pears not being good, although produced by fine trees trained against walls? He complains of the season; but it is in most cases owing to the trees being allowed to bear just double the number they ought to have done. It is the same with Plums and Apricots, and, indeed, all kinds of fruit, as well as that of orchard-house trees. I could illustrate this by several cases, but one will do.

In 1861 I had a very thin crop of a favourite sort of Plum, of which a large number are annually preserved. During the winter of that year, and till late in the spring of 1862, these preserved Plums were very frequently on the table, their aroma on a tart or pudding being opened was most delicious. Last year the crop of these Plums was so abundant as to hide the leaves. Thinning was not thought of, as the trees were so numerous. The usual quantity were preserved, and have been in use up to the present time. They are perfectly sound and good, but the fine aroma peculiar to them in seasons when they are thin on the trees is entirely wanting. The following ought to be inscribed on every wall, and in every fruit and orchard house:—By thinning you make indifferent fruit good. By crowding you make good fruit bad.

With regard to trees in pots, and trees planted out in orchard-houses, I have charming specimens of both. I like both modes of culture, but the perfect control exercised over trees in pots by the facility of removing them to force or retard them, or the great pleasure of placing a tree or trees full of fine fruit in the entrance-hall, so that your friends may see the fruits of your labour, is so gratifying that no caviller can once arrest the progress of pot-culture. The oddest thing is that men who oppose this description of culture have never gone into it, but have merely skirmished; and, after a faint attempt at a charge, have been repulsed by their old and cherished friend Prejudice, who always keeps his bayonet fixed and pointed at their brains, ready for action if they try and release themselves from his shackles.

A few words more about thinning fruit and I have done. If very fine and high-flavoured fruit are wished for, a tree capable of bearing three dozen of medium-sized Peaches should be allowed to bear only twelve or fifteen. This thinning is terrible work for the amateur—it is like drawing a tooth, and every fruit that falls to the ground creates a pang; but it must be done. A small sharp penknife is the best implement to employ, and is much better than tearing off the fruit with the finger and thumb. A well-formed Peach or Nectarine tree, be it bush or pyramid, with its fruit properly thinned and nearly ripe, is one of the most beautiful objects the skill of the cultivator can produce. No Camellia, or Orchid, or Rose tree can be more so. Yet this is an object for which some gardeners "feel contempt!"

What "a heap of words" has that paragraph written by "D." of Deal, called forth! I have only to apologise for my attempt to show that contempt ought not to be felt for anything in nature that the skill of a persevering good gardener can make interesting and beautiful.—R., of S.

SALE OF ORCHIDS.—On the 8th Mr. Stevens, at his Auction-rooms, King Street, Covent Garden, disposed of a very superior collection of established Orchids, some the property of a gentleman, and others recently imported. All the lots, 195 in number, realised good prices, but we can only afford space for particularising a few of them:—Vanda Lowii, strong plant, £9 15s.; *Ærides Schroederi*, very fine young plant, £16; *Cypripedium caudatum*, good plant, £7 10s.; *Phalænopsis Schilleriana*, fine young plant, £11; *Cypripedium hirsutissimum*, good plant, £5 10s.; *Cymbidium eburneum*, true, fine plant, £15 10s.; *Saccolabium species nova*, Philippine Islands, £5; *Cattleya Trianaei*,

extra fine, £5; *Cypripedium Stonei*, new and rare, £5 15s.; *Cypripedium species nova* (Veitch), very rare, good plant, £10 10s.; *Europedium Lindenii*, fine plant, £6; *Trichopilia suavis*, strong plant, £6; *Trichopilia crispata*, the finest of all the *Trichopilia*s, splendid plant, £25 10s.; *Dendrobium luteiflorum*, strong plant, undoubtedly one of the finest *Dendrobium*s in cultivation, £26.

LIST OF ANNUALS.

BEING a grower of annuals, &c., for a London house, I beg to add a few more names to the list of your correspondent of Newport, in the *Journal* for March 31. They are annuals which I think are well worth a place in any garden.

- | | |
|--|--|
| 1. Aster, cockade or crown. | 27. <i>Lupinus nanus</i> and others. |
| 2. <i>ranunculus-flowered</i> . | 28. <i>Nemesia compacta elegans</i> . |
| 3. <i>Acrocinium roseum</i> . | 29. <i>Nigella hispanica</i> . |
| 4. <i>Calandrinia speciosa</i> . | 30. double Roman. |
| 5. discolor. | 31. <i>Obeliscaria pulcherrima</i> . |
| 6. <i>Calliopais tinctoria</i> . | 32. <i>Enothera Drummondii</i> . |
| 7. <i>Callirhoe pedata</i> . | 33. <i>bistorta Veitchiana</i> . |
| 8. <i>Cerinthe gymnantra</i> . | 34. <i>Lamarckiana</i> . |
| 9. <i>Centranthus macrocephalus</i> . | 35. <i>Oxalis rosea</i> . |
| 10. <i>Chenostoma polyantha</i> . | 36. <i>Petunia</i> , Buchanan's blotched. |
| 11. <i>Clarkia elegans rosea</i> , double. | 37. <i>Podolepis gracilis</i> . |
| 12. <i>pulchella integrifolia</i> . | 38. <i>chrysanthos</i> . |
| 13. <i>Collinsia bicolor</i> , pure white. | 39. <i>Poppy Carnation</i> (in six varieties, double). |
| 14. <i>Collomia coccinea</i> . | 40. <i>Sanvitalia procumbens</i> . |
| 15. <i>Cosmidium Burridgeanum</i> . | 41. <i>Scabiosa</i> , fine German mixed. |
| 16. <i>Datura ceratocaulon</i> . | 42. <i>stellata</i> . |
| 17. <i>Didiscus coruleus</i> . | 43. <i>Sedum azureum</i> . |
| 18. <i>Erysimum arkansanum</i> . | 44. <i>Sphenogyne speciosa</i> . |
| 19. <i>Helichrysum macranthum</i> . | 45. <i>Statice Bonduelli</i> . |
| 20. <i>brachyrhynchum</i> . | 46. <i>Suitan</i> (three varieties). |
| 21. <i>Hibiscus africanus major</i> . | 47. <i>Valerian</i> , garden (two varieties). |
| 22. <i>Thunbergi</i> . | 48. <i>Verbena aubletia</i> . |
| 23. <i>Larkspur</i> , branching tricolor. | 49. <i>venosa</i> . |
| 24. double white. | 50. <i>Whitlavia grandiflora</i> . |
| 25. <i>Lobelia gracilis compacta</i> . | |
| 26. <i>Linaria bipartita</i> . | |

8 and 31 are more curious than pretty, but I think are worth growing; and 16 for its beautiful scent in the evening, a long way off. 3, 19, 20, 42, 45, are all very pretty; also noted for dried flowers for winter bouquets. 43 is very pretty on rockwork; 18, very showy, more so than *E. Peroffskianum*.

You say that 41 in your correspondent's list from Newport, you are not much acquainted with. It (*Oxalis tropaeoloides*), makes a very nice edging for beds, &c., having very dark brown foliage and small yellow blossoms; but once get it in the bed and you cannot destroy it, it seeds so heavily. 49 is very handsome, but so very delicate that a shower soon spoils it. 15 is a compact plant with small golden flowers.

I should like to see annuals grown more widely; I think there are so many really very beautiful and easily grown. They do not require that nursing that many of our flowers in beds at the present time demand.—S., *South Weald*.

THE FIRST IMPROVER OF THE PANSY.

I PRESUME that your respected and practical correspondent, Mr. Robson, has not grown grey in his profession, as in his paper on the subject of the Pansy, No. 105, March 31st, he says, "It is impossible to say at what precise period the parent of our garden varieties of the Heartsease or Pansy first attracted the attention of some zealous and far-seeing florist." I have been an amateur for more than fifty years, and can well remember the introduction of the Heartsease.

The Heartsease, though a native of Britain, was never cultivated in order to render it a florist's flower, till taken in hand by Mr. Thomson, of Iver, Bucks, and by him was brought into admiration; and from his original stock have all the beautiful varieties of the flower been produced, and in the south and west of England he was called the father of the Heartsease.

Mr. Thomson was gardener to the late Admiral Lord Gambier, who resided at Iver, Bucks, near Uxbridge; and Mr. Thomson says, in a paper now before me, that in 1813 or 1814, Lord Gambier brought him a few plants collected in the fields near the mansion at Iver. They were the yellow and white, and his lordship requested him to cultivate them. "Having done so, it was soon discovered that a great improvement was effected in the flowers, and this led to as many other sorts being collected as could be discovered in the neighbourhood. About four years after this commencement I had raised many seedlings from the originals; and one which took Lord Gambier's fancy was named

Lady Gambier, another George IV., a third was called Ajax. The first good-shaped flower was named Thomson's King."

At the time Mr. Thomson was making these improvements in the Heartsease, I resided some six or seven miles from the place, and often and great was the pleasure to go over his seed-beds and watch his colony putting forth their beauties for future fame, I can conjure them up before me while I am now writing, even at this distance of time.

At that time the only mark in the eye of the Heartsease was a few dark lines, and the dark eye which is now considered one of the chief requisites of a first-rate flower had never been seen, or even contemplated. Nor did Mr. Thomson take any merit to himself for this peculiar property; for one day having a chat with him on the subject, and complimenting on the same, he said, "It was entirely the offspring of chance. On looking one morning over a collection of Heaths which had been sadly neglected, I was struck (to use a vulgar expression), all of a heap, by seeing what appeared to me a miniature impression of a cat's face steadfastly gazing at me. It was the flower of a Heartsease self-sown, and hitherto left to 'waste its beauty' far from mortal's eye. I immediately took it up, and gave it 'a local habitation and a name.' This first child of the tribe I called Madora, and from her bosom came the seed which after various generations produced Victoria, who in her turn has become the mother of many even more beautiful than herself."

Thus the origin of the cultivated Heartsease; and so many varieties did Mr. Thomson raise, that he has told me he was often forced to go to Shakespeare for a name for them. Since his time so many persons have carried on the cultivation that the varieties are now almost endless.

It is now more than twenty years since I have heard of Mr. Thomson; but, if still in the land of the living, I hope he is receiving the reward of his perseverance and industry.—DAHL, *Manchester*.

[Soon after Mr. Thomson had thus improved our native Heartsease, Mr. Archibald Gorrie adopted this pretty flower as a pet. He has recorded that about 1824 he received two varieties from Mr. Brown, of the Kinnoul Nurseries, with an injunction to pay attention to their culture. He raised many varieties from them, and the names of some of the best will be found in Loudon's "Gardener's Magazine" for 1832. Mr. Gorrie was the first, we believe, to obtain for the Pansy admission to the rank of a florist's flower, and with great difficulty he secured its introduction into the schedule of the Perthshire Horticultural Society.—Eds. J. OF H.]

THE TRUE GILLIFLOWER.

HAVING heard sometimes the Stock, and sometimes the Sweet William, called "Gilliflower," would you tell me which is the "true Gilliflower?" Also, what is the botanical name of the common Wormwood?—A NOVICE.

[The true "Gilliflower" is the Carnation. The Stock, it has been said, was called the "Stock Gilliflower," because it was sold chiefly in "Stocks Market," the old herb-market in Bucklersbury; but Dodonæus states that in Holland it was called the Stock Violet (stemmed Violet), and that certainly had no reference to the English herb-market. It seems more probable that the term "Stock" was applied to distinguish it by its habit of growth from the Carnation or Gilliflower. We never heard of the Sweet William being called the Gilliflower. The botanical name of the common Wormwood is *Artemisia vulgaris*.]

IS NIEREMBERGIA GRACILIS HARDY?

I HOPE for a reply in the affirmative, knowing as I do that it will stand any moderate winter in a partially sheltered border entirely unprotected out of doors. Indeed, I never could have brought myself to the belief that this small, graceful-habited plant could have assumed so striking an appearance had I not seen it. Let the reader fancy to himself a plant of this bright little plant, some foot and a half in diameter, covered with a mass of fully expanded blooms, in the moderately heated rays of the sun upon a forenoon in early June, and count side by side some eighteen or two dozen of the same. I can truly say that the effect is most pleasing.

It may be worth while to try this upon a moderately dry sheltered spot. Seen as above, they were planted in one of

those narrow borders fronting a stove; trained against the low front wall of which were nice plants of some of our most shy-blooming Tea Roses. Could the Belladonna Lily be grown in the same border? How it would enhance the appearance of the flowers if their naked lower-stalks were partially hidden amid the gracefully growing foliage of this charming little plant.—W. EARLEY, *Digswell*.

APRICOTS IN ORCHARD-HOUSES.

I PROMISED to give the result of an experiment with Apricots under glass.

Some of your readers will recollect I suggested trying the effect of sprinkling the shoots and blooms of Apricots early in the day with water from the fine rose of a watering-pot, thinking it might be beneficial. I selected several trees, and watered them almost every day before and during the time they were in bloom. Now for the result. They are neither better nor worse than those which have never been sprinkled. There is so much fruit on all the trees that a large proportion must be pulled off. Mr. Brown, of Lenton, near Nottingham, who has been trying the same experiment, says he is quite satisfied that an occasional sprinkling has proved beneficial to his trees; I have only proved it is not injurious.

I hope Mr. Robson will not consider me influenced by interested motives alone in advocating orchard-houses. I can assure him there is such a thing as riding a hobby for pleasure as well as profit. I have taken more interest in my fruit trees in pots, and derived more pleasure from their management than in any other culture.

Last year was the only season when I had a partial failure with Peaches and Nectarines, and two of the best gardeners in this neighbourhood—Mr. Ingram, of Belvoir, and Mr. Speed, of Mansfield—said I had as good a crop as could be expected on the average. Even this partial failure was partly accounted for, many of the trees having been lifted from the borders of an old orchard-house, in which they had been growing for two years, and potted only five months before they came into bloom.

If Mr. Robson will pay me a visit I will try and make it a pleasant one to him, and do not despair of making him a convert to orchard-house culture. If my fruit from potted trees are as good as usual, he will not call them small (I weighed one last season, $7\frac{1}{2}$ ozs., a Walburton Admirable), and I am sure he will not find fault with the quality.

In 1861 a nobleman's gardener made me an offer of 7s. per dozen for my Peaches, but I did not sell them, as I wished those who came to see them to have an opportunity of tasting. From fifty to a hundred dozen of Peaches and Nectarines have been eaten annually by my visitors and friends, and I never yet met with more than one person—a gentleman who had resided at the Cape, and who was, perhaps, very thirsty when he ate Peaches there—who ever pretended they had eaten better, whilst scores have declared they had no idea of what a Peach ought to be before tasting one in an orchard-house.

I think those who speak against growing Peaches in pots can have no idea how many persons differ from them in opinion. I appeal to any of the great nurserymen if the sale of Peaches and Nectarines has not doubled at least since orchard-houses were erected. I know that we sell far more than double; and, whatever some persons may think, I have no doubt twice as many trees will soon be required.

Now, Mr. Editor, please tell us, who believe in the orchard-house, what more can we do to convert the infidels? We ask all to come, and see, and taste. We refuse to sell our specimen trees, because persons would say they had died and had been replaced, so we keep the same trees we commenced with: can we do more?

In conclusion, let me say Pears are not grown in my house, because they were never good with me. The few Plums grown bear very constantly and profusely, and are little different in quality from those grown in the open air. Apricots have been rather uncertain bearers; they have never totally failed, though they nearly did so last year. They have often been a full crop. The quality has always been greatly superior to wall Apricots, so much so that if they were more uncertain they would be worth growing. I never fear a failure in Peaches and Nectarines, as the crop was a good one in 1861 in spite of the sunless summer of 1860; and the worst spring for fruit-blossoms ever known perhaps, that of 1862, was followed by a half crop of first-rate quality.

If I live, some of my Peaches shall find their way to the Fruit Committee and receive a verdict from the honourable members. And if Mr. Robson pays me a visit, which I hope he will do, he will not find the pots fast to the ground!—J. R. PEARSON.

[We recommend Mr. Robson to accept the invitations of Mr. Rivers and Mr. Pearson, and to dine with each in the height of the Apricot season; for we can promise him that he will find first-rate Apricots on their tables from their orchard-houses, and we can promise his hosts that they will find their guest anything but a man obstinate and prejudiced.]

We have cultivated Vines, Peaches, Nectarines, and Apricots in an orchard-house, and succeeded with all. Certainly finer Black Hamburgh and Champion Grapes and Moorpark Apricots we never desire to have upon table. Of course the produce per tree was small.—EDS.]

MERITS OF ORCHARD-HOUSES.

AS "D.," in his letter in last week's JOURNAL OF HORTICULTURE, says that most practical men have a contempt for fruit trees in pots, and follows up by a sneer at orchard-houses and their originator, perhaps you will allow me a few lines to give you my experience of their success, at least as regards Peaches and Nectarines, and I think I shall show that they are by no means such failures as he would intimate them to be.

In the summer of 1859 I built an orchard-house of clay-lump at an expense of about £28, 20 feet 6 inches by 12 feet, with the border returned at the further end. I should build another one somewhat cheaper and with various slight improvements. I stocked it from the Sawbridgeworth Nurseries at an expense of £6 1s., with sixteen Peaches and Nectarines, four Apricots, three Plums, and one Cherry; to which I afterwards added four Vines—on the whole too much by a quarter for the house.

The Plums, Vines, and Cherry I may dismiss at once, with an acknowledgment that I could get no blossom to set on the Plums and Cherry, and but few bunches and those very poor on the Vines. The Apricots have not done well. I have never had more than six or eight on a tree, those, however, large and well-flavoured. The Peaches and Nectarines have, however, been a great success. The first year I averaged somewhat more than a dozen on each. In 1860, when there was a large quantity of wall fruit out of doors everywhere, but utterly flavourless from the continued wet, I had an average of about two dozen on each plant—far better flavoured than out of doors, as I had the regulation of the water-supply in my own hands.

Then came the fearful winter 1861-2, which in this neighbourhood killed-down many exposed trees, while those which did survive bore no fruit on their badly-ripened wood. I, however, in the orchard-house had a supply somewhat larger than the previous year, no tree having been at all damaged by the frost. Last year I gathered from these sixteen trees nearly five hundred Peaches and Nectarines, one-third, perhaps, smaller than they should be, but the remainder of good size and flavour. In the latter point I can, in average years, perceive no difference between out-door and in-door fruit, nor in the former point where not more than—say, thirty fruit are allowed to swell on a moderate-sized tree.

I think, then, that as far as these trees are concerned they are by no means a failure, but decidedly a very great success. But "D." will say, "You have a clever man whom it pays to give a large income to" (I quote his own words). I am, or was till six months ago, my own head-gardener, and no experienced amateur either, but till I had my plants and Rivers's book I had never pruned a Peach, nor knew the difference between a leaf-bud and flower-bud; and I may say in passing, that it is a great pity that trees will never grow according to the descriptions and diagrams by which the tyro is instructed how to prune them.

My aide-de-camp was one of those hybrids between groom and gardener, whose qualifications consist in knowing very little of either business. However, he would do as he was bid.

In conclusion, I would strongly advise every one who wishes for a certain crop of good fruit and cannot afford much space, nor the expense of a large wall, and does not wish to wait for his crop for four or five years to build such an orchard-house as he can find room for, to buy Rivers's book and set to work by it, putting-in only Peaches and Nectarines. Ten minutes in the morning and half an hour in the evening, with one day

in the autumn, and another—or say two—in the spring, are the attendance it will require. He cannot know less about fruit trees than I did when I began; and if he fails, some people are very clever at failing, let him not come to me for sympathy, as I shall certainly tell him it is his own fault.

It is foreign from the main object of an orchard-house to enlarge on its convenience as a harbour for plants not quite hardy—*Rhododendron ciliatum*, *Vallota purpurea*, Tea-scented Roses, *Fuchsias*, &c.; but I have found it exceedingly useful for such purposes.

My trees—with one exception, overdosed with Gishurst and not likely to set more than a score of fruit—are now masses of blossom, and the Apricots setting better than they have done.—*DUCKWING*, ——— *Rectory*.

RATING NURSERY GROUNDS.

IN No. 104 you very kindly gave us some valuable information as to the liability, or, rather, non-liability of nurserymen's greenhouses and hothouses to be rated. Will you now give us a few words as to ground employed for raising trees?

My case is as follows:—I have some land planted with young nursery stock without buildings of any kind on it. It is bounded on the north by arable land, and on the west by land of the same description, divided by the usual fences of the country hedge and ditch. This arable land is occupied by farmers, and is assessed at—say, in round numbers, 30s. per acre. The Assessment Committee of the parish, much impressed with the value of my stock, wish to assess my land at £4 10s. per acre, or 200 per cent. more than the land adjoining. This I resist, and say, I think, justly, that although my land has been improved by deep digging so as to be worth to any ordinary tenant 10s. per acre more than the adjoining land under the plough, it ought not to be assessed at the high rate they name, the neighbouring land being of exactly the same nature as mine, both in surface and subsoil. I am well aware they have no business with my stock, but it seems they are impressed with the idea that I get a much larger profit from my land, and that, consequently, it ought to pay more to the poor's rate.

With respect to the land on which my glass houses stand, one acute reasoner suggested that a greenhouse or hothouse should be considered as a manufactory; and that as a manufacturer, on building a factory and placing in it a steam-engine to be employed in his business, would be at once rated for it, so in like manner a nurseryman building a propagating-house and using hot water to propagate plants, was a manufacturer, and his house or houses should be rated as factories. This is a new idea not likely to hold water, but ingenious, and worthy of one of "the wise men of the east."

The gentleman who ushered it into the world ignored entirely the precedents you quote in No. 104. A few words from your experienced pen will at the present moment be of great service to many of your readers.—*A NURSERYMAN*.

[No mistake is more commonly made by parish officials than concluding because A makes more profit from an acre than is made by B from an acre of the same land, that therefore B should not pay so much as A; the absurdity of which is at once further shown by the consideration that if such were the law, then a man's skill and industry would be the measure of rating. Such, we think, is not the law, and we further think that "A NURSERYMAN'S" ground, as described, can only be legally rated at what it would let for to a neighbouring farmer after all the nursery stock was removed.

The rule for rating manufactories and town trades is not at all applicable to cultivators of the soil, and has long since been so determined.—*EDS. J. OF H.*]

A FEW DAYS IN IRELAND.

LYONS.

(Continued from page 263.)

HAVING felt much interested in the state of the first vinery we entered, we obtained the following details, which show that often much may be well done, and yet the good be neutralised by some trifling misconception or error of judgment. The strong character of the wood showed there was plenty of nourishment.

The tendency to luxuriance, rather than extra fruitfulness, and the liability to shanking and imperfect colouring, led to the conclusion that the roots were too deep, or in stagnant moisture more frequently than was good for them; and yet almost everything had been done, and done very well, to prevent such a thing. A drain 7 or 8 feet deep went along beneath a walk in the front of that border; and at a depth of from 30 to 33 inches the bottom of the border had been securely flagged to prevent the roots going down into ungenial soil, but with no open rubble between the soil and the flagstone. To make matters more sure, and, as if flagstones were of no cost, there were some 9 inches of stiff soil beneath that flagstone, then another flagstone bottom, then a good depth of open rubble beneath that, and most likely other floors of flagstone—enough to have done many borders, if flagstones were deemed essential; and we have nothing to say against them if on a slope, and rubble above them, so as to prevent water lodging on them. Well, how was it possible that the Vine roots should be exposed to extra moisture in such an expensively-made border? From several trivial causes. The drain had been securely built with mortar, and the better the mortar the less free access would the moisture of the border have to it. Then, again, as if to secure this closeness properly, a bank of rather stiff clay had been packed between the drain and the border, and no direct openings whatever existed between the border and the drain. The bulk of the roots were close to the flags, and many had penetrated the wall of clay, and had descended and run along the surface of the close drain.

The roots being carefully lifted, we might have been satisfied with placing small drain-tiles on the flagged bottom, communicating directly with the close drain, and covered these and the flags with from 6 to 9 inches of rubble; but Mr. Lind did more than this—he broke through the bottoms of flags every 4 feet or so, took four-inch drain-tiles right across into the main drain by openings, covered these cross drain-tiles with 2 feet of open rubble, covered the flags with 9 inches more, and put a good thickness of stones over the main drain, so as to let moisture down freely to the openings. He then, in partly fresh soil, replanted his Vines nearer the surface, the border being from 18 to 21 inches deep, as forming fresh roots quickly was a chief object. The soil used was without manure; but with such drainage manure water may be used to any extent in summer. The results in handsome fruit, well coloured and free from shanking, and good firm short-jointed wood, are everything that can be desired. The earlier such lifting and replanting are done in autumn the better, even if shading and syringing should be resorted to, to prevent the leaves flagging. The heat of the soil should also be kept in by covering early with litter; and in the following season Mr. Lind farther encouraged root-action by stopping several joints beyond the fruit, and encouraging more laterals than usual, until the balance between roots and branches was thoroughly restored.

We might detail other more simple modes of bettering the condition of Vine roots, such as making openings in such a close drain, and filling up with rough stones to near the surface after moving the clay bank; or we might describe another case, where Vines were planted in the front of the house inside, where little or no attention had been given to drainage, and where, from the tops of the arches for letting the roots out being 18 inches below the outside surface, the roots had chosen to march right down instead of going outside at all; and how these Vines were wonderfully improved by lifting these deep perpendicular roots, removing the sour soil in the arches, raising the openings so as not to have the arch more than 6 inches below the surface of the border, and taking the roots through at the top of the heightened arch and packing them in fresh soil. But we pass these with less regret, as there has been no end to reiterated advice on such matters, and great stress laid when planting inside, not only that the openings for the roots should be near the surface, but that the inside border be higher than the outside one.

Although it was getting dark, the impression of the glass houses conveyed to our mind was, that the same care was not bestowed upon their external appearance and condition as was observable in other departments of the demesne that came under our notice. This, however, is far from being uncommon in many large places, where, if a glass house is put up, it is supposed to need no more looking-after for a generation; and if we blue aprons do say anything about drippings and inundations from worn-out or imperfect glazing, we are set down as a grumbling lot that nothing will satisfy; and in truth we

are not easily satisfied, and many more little things might be done to satisfy our desires, but for an idea that gentlemen have, that if they admit so much as our little finger they may make up their minds to let in our whole hand.

The main range is 175 feet in length, consisting of Peach-house, stove, small greenhouse, and three vineries. The height of these houses at back is $12\frac{1}{2}$ feet, width $11\frac{1}{2}$ feet, and height in front $3\frac{1}{2}$ feet. There are also a very nice forcing-pit 36 feet in length, and a Melon-pit 44 feet in length; and though last, not the least valuable, there is a capital span-roofed orchard-house 80 feet in length, 20 feet in width, 10 feet in height from floor to ridge, side walls $4\frac{1}{2}$ feet in height to the eaves, with ventilators about the middle of the sides. There is a door in the centre of each end, and over the doorway a ventilator 1 foot by 2 feet, and that with the openings in the sides is found quite sufficient. The house inside has a bed along the centre 7 feet wide, divided into two by a cross-walk, where there is a cistern for water and a force-pump. There are also a border on each side, 2 feet 10 inches wide, and a walk 3 feet wide all round. These borders are raised above the pathways 16 inches. On each central bed are two large Peach trees planted out, and the rest for filling-up are grown in pots. On the side-beds several trees of Peaches and Plums are planted out, and the rest are retained in pots, and all were looking very promising. When red spider makes its appearance at all, Mr. Lind generally uses the sulphur and lime remedy recommended by Mr. Rivers, but says it must be used cautiously, and that the leaves, &c., cannot well be too dry. As a wash for fruit trees in a dormant state, he uses a solution of lime fresh from the kiln and flowers of sulphur, and is seldom troubled with any insects. The wash crumbles and peels off during the season, and no insect likes to come near the dust that is left. We should not wonder if, after after all our fine mixtures, we go back again to some of the old and simple ones.

The mode of heating the houses is well deserving of notice. It is not by common flues and furnace, nor by any system of hot water or steam, nor yet by any combination of Polmaise, or any modification of the hot-air chamber of Mr. Kidd, or of the killogie once propounded by that natural genius, Mr. Alexander Forsyth, who seems of late to be keeping his light under a bushel. No, by none of such means, but simply by old-fashioned flues heated by limekilns. Under Mr. Lind's supervision the system answers admirably; the plants in the stove, &c., looked in excellent health, and Peaches are generally gathered in the beginning of May, and Grapes cut in the beginning of June;

1. Open shed over each kiln.
2. Solid stone work.
3. Eye of the kiln.
4. Damper.
5. Flue passing below the floor of the houses to be heated.

Strawberries, &c., being obtained proportionately early, though they could also be had earlier if required.

A great deal of lime is wanted on the estate, and the system has been adopted as one of great utility and economy, it being believed that the houses are heated much more cheaply than they otherwise would be, and that the lime is a substantial gain besides.

The annexed is a section of one of the limekilns, which are only used when heat is wanted for the houses, showing the open shed over it, and the flue passing at first underneath the ground level. The * marked on section represents the place where the workman wheels his fuel and limestone, and tilts them into the kiln. Each kiln is 7 feet deep, tapering to a narrow base at bottom, where the eyehole is placed for removing the burnt lime with a shovel in the usual way. The middle of the kiln is $3\frac{1}{2}$ feet wide, somewhat egg-shaped, and the top is $2\frac{1}{2}$ feet wide, and covered with a stout iron griddle or lid 1 inch thick. The sides of the kilns inside are lined with firebrick, which is supposed to last at least four years without any repairs. When heat is wanted the kilns are never out, unless when such repairs are needed, and Mr. Lind spoke of one that had been worked continuously for three years, and never been out, and to all appearance might work on ever so much longer without any repairs being necessary. When heat is not wanted in some of the houses in summer, the kilns are allowed to go out, the object being to make the lime only when heat is wanted. From November, when more heat is required, the lime is very good, and used solely for building purposes. On an average each kiln produces six bushels of lime per day.

The fuel used is cinders and ashes from the mansion, culm, and inferior coal from Queen's County, abounding in sulphur, slack, small coal from the depôt, and braize or refuse from the Dublin gas works, which answers better than any of the others, but cannot always be obtained. The limestone is brought from an estate of Lord Cloncurry's, and is carted to the canal bank for 2s. per ton. From thence the limestone and fuel have to be carted half a mile to the garden. At the canal bank the culm is obtained at 12s., the slack coal at 12s., the braize at 8s. 6d., and the limestone at 2s. per ton. Mr. Lind kindly furnished us with the following data, as a means of judging of the power of the different kinds of fuel, and the value, economically, of the whole process:—

One ton of culm at 12s., will produce 31 barrels of lime.

One ton of slack at 12s., will produce 27 ditto.

One ton of braize at 8s. 6d., will produce $35\frac{1}{2}$ ditto.

The barrel is a local measure holding 11 stone avoirdupois, we think, of lime. The price of lime delivered also at the canal bank, is from 10s. to 11s. per ton. By taking the price of limestone 2s. per ton, the price of braize 8s. 6d., and the value of the thirty-five and a half barrels of lime, at eleven stones per barrel, it will be no difficult matter to arrive at a conclusion on the economical aspects of the question, so as to be worthy of the consideration of those who can obtain plenty of limestone or rough chalk without costing much except the labour.

As to the management, Mr. Lind stated that the kilns were rather troublesome in windy weather, but that otherwise he would as soon have them as common furnaces and flues, and that when managed regularly by one person they constituted a source of scarcely more anxiety than heating houses generally does. It is expected that when at work the kilns will be in good order—that is, the fire well up through them at five o'clock in the afternoon or soon afterwards. Suppose this to be the case, the houses will want looking to about seven, and most likely the heat will want regulating by the damper. At ten o'clock the houses will be looked to again and the heat regulated for the night, which generally leaves the house just warm enough in the morning, as when this attention is given the heat is very regular. If the heat is too much the damper can be put in for a time, and the cover to the kiln moved partly or altogether, just as in a similar case in a furnace we would open the furnace-door. In either case, of course, the extra heat is lost, but in each like the damper is the regulator when there is excess of heat. Our friends who so strongly contend for hot water in all cases, may rest assured there are many modes of heating effectually, if the operators, as in the present case, bring intelligence and a spice of enthusiasm to bear upon the subject.

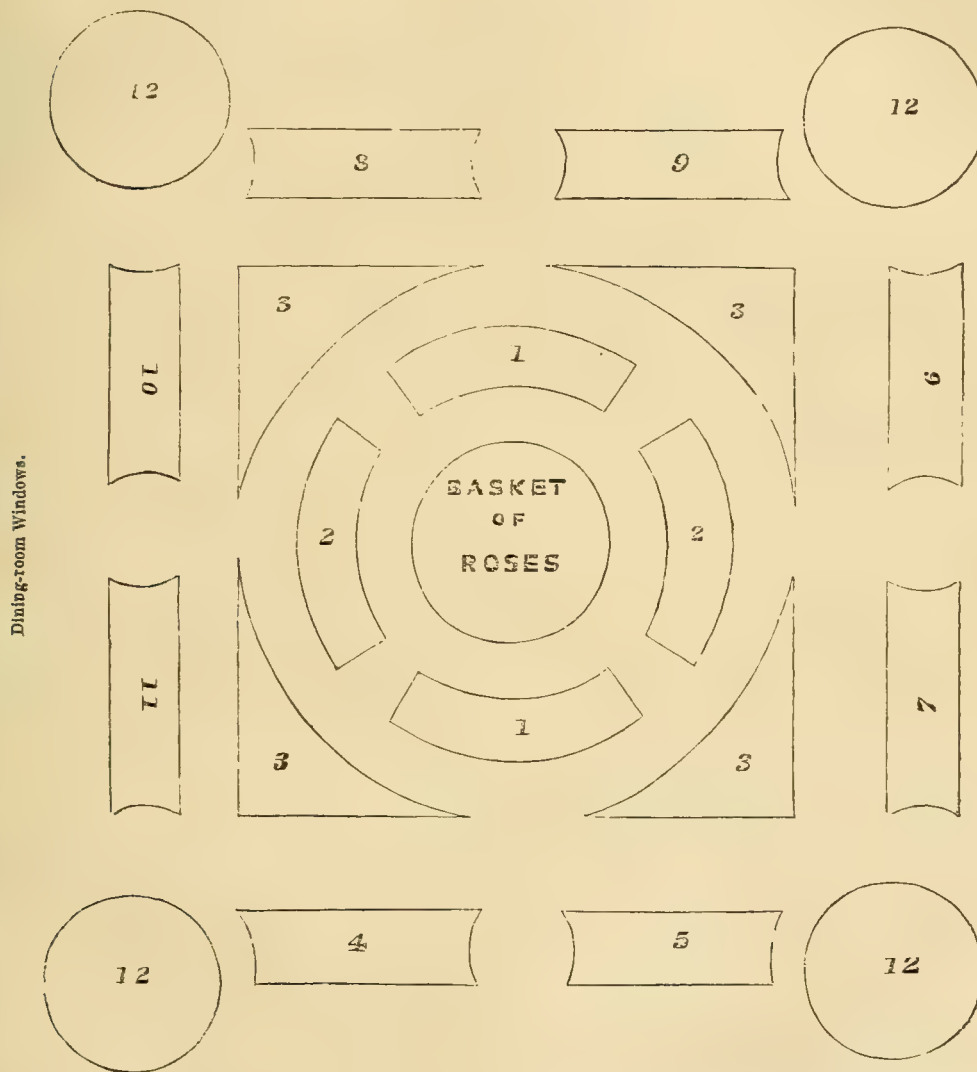

With darkness in the gardens, and a cheering cup of tea from Mrs. Lind, and a pleasant converse afterwards, terminated one of the most delightful and instructive of days in a gardening point of view.

Some friends and unknown correspondents have thought proper to call in question the heading of these sketches, "A Few Days in Ireland." But they are quite correct and consistent, as may be judged from this single day's work. We left Dublin early and spent the morning at Hamwood, the forenoon at Carton, the afternoon at Straffan, and the evening at Lyons. No such amount of work could have been gone through but for the kindness of Mr. Robertson, of Mary Street, Dublin, who not only planned

the routes, but prepared for us in almost every case a most warm and friendly reception. With all that, however, we were tired enough on getting to Dublin; nor is it to be wondered at, that, in our snug room at the Verdun, very sound sleep was prevented by visions of columns and towers, Italian gardens, halls of shells, endless lakes, and the blowing-up of forcing-houses by gigantic limekilns.

R. FISH.

FLOWER-GARDEN PLAN.

DESCRIPTION OF BEDS.

1, 1, Tom Thumb Geraniums.
2, 2, Madame Vancher.
3, 3, 3, 3, Purple King Verbena, edged with Yellow Calceolaria.

4, 5, 6, 7, 8, 9, 10, 11, To be planted ribbon fashion in three rows:—
1st row, Mangles' Variegated; 2nd, Christine; 3rd, blue Lobelia.
12, 12, 12, 12, scarlet Verbena Foxhunter.

THE following remarks are relative to a flower-garden plan sent us by S. E. L.

We admire your arrangement chiefly for its great elegance and simplicity, and heartily wish the mere strivers for variety would take a lesson out of your book. There is only one fault we notice, and that is your large basket of Roses in the centre. It will dull your whole figure in the autumn. Just think of the effect of a ringed bed, or one of Alma with a lilac border. All you can do now is to have a good border round the Roses, and plant a few things among them. For the 3-beds you will, of course, use a low Calceolaria. In the long eight beds, perhaps, according to your arrangements of Mangles', Christine, and Lobelia,

it would be as well to have Christine in the middle, because Mangles' will pin down so nicely to suit the Lobelia. All these eight beds will be relieved by the planting of the 3's and the blaze in 12's; and we should like to see the whole in perfection, to be, if possible, more convinced that a few colours well managed will do wonders. Leaving 4, 5, 8, 9, as above, you might for variety have a little difference in 6, 7, 10, 11—such as Tom Thumb or Boule de Feu, centre; Christine, middle, or Flower of the Day; and Lobelia Paxtoniana, or Verbena pulchella, or Charlwoodii for outside. We notice this, however, merely for variety, convinced that your plan of having all the eight beds alike will look quite as well.

GISHURST COMPOUND.

MAY I suggest to your correspondent "S. P." that instead of condemning Gishurst altogether he should, next winter, try, instead of the eight-ounce solution he used, one of half the strength? This I tried on some of the more susceptible sorts of trees this season in January after the buds had swelled much, with the result of their neither browning nor falling. I think, after the paragraph giving the Van Mons Society's experience, which immediately followed "S. P.'s" note, that the medicine may still be considered valuable, though the dose may have proved too strong in the cases of particular patients. I use 8 ozs. because I find my trees the better for it; but after finding, even in exceptional cases, that the eight-ounce solution had been too strong, I recommended half this strength.—GEORGE WILSON.

THE ROYAL BOTANIC SOCIETY'S SECOND SPRING SHOW.

THIS took place on Saturday last, and the display, especially of Azaleas, was excellent.

Those from Mr. Turner, of Slough, were admirable examples of cultivation, being regularly-grown pyramids, and covered with a profusion of bloom. They consisted of Rosy Circle, Prince Jerome, Admiration, Criterion, Iveryana, and Holford. He had besides in the class for new sorts, Perfection, a bright rose spotted with crimson; President, rosy salmon; and Duke of Saxony.

Messrs. Ivery & Son, of Dorking, had also a nice collection, consisting of Criterion, Baron de Vrière, Iveryana, Louise Margottin, and Adelaide de Nassau.

Mr. Cross, gardener to Sir F. Goldsmid, Bart., and Mr. Todman, gardener to R. Hudson, Esq., Clapham Common, had excellent specimens in the Amateur's Class.

Hyacinths did not afford a great display. Those from Messrs. Cutbush, of Highgate, and Mr. Carr of the same place, were by far the best; and among them were some very good spikes of Van Speyk, Macaulay, Von Schiller, and other kinds which have been frequently noticed in these columns during the present spring.

Cut Roses were again shown in great perfection by Mr. W. Paul, of Waltham Cross, and Messrs. Paul & Son, of Cheshunt. In Mr. W. Paul's collection, which consisted of eight boxes, were some beautiful blooms:—Teas, Louise de Savoie, Eliza Sauvage, Niphetos, Vicomtesse de Cazes, Devoniensis, and Gloire de Dijon; and of Hybrid Perpetuals, Beauty of Waltham, Pauline Lanzeur, Louise Peyronny, Olivier Delhomme (of a glowing purplish-red), and three lovely blooms of Victor Verdier, two of which were just opening. In Messrs. Paul & Son's seven boxes, among the most striking were Narcisse, Eliza Sauvage, Madame de St. Joseph, Louise de Savoie, and Madame Willermoz; and H.P.'s John Hopper, Victor Verdier, Maurice Bernardin, Jules Margottin; and H.B. Charles Lawson, the last a lovely bright colour and very large and full.

Of Pot Roses the only exhibition came from Mr. W. Paul, who had Sénateur Vaisse, with its beautiful bright red flowers; Victor Verdier, large and fine; Catherine Guillot, very fine; and among dark colours Cardinal Patrizzi and Triomphe de Lyon.

Of Begonias there were several collections shown, the exhibitors being Mr. Cross, Mr. Fox (gardener to R. Gibbs, Esq., of Highgate), and Mr. Webb (gardener to J. L. Latham, Esq., of Highgate). The whole of the plants were well grown, but among the kinds shown there was nothing remarkable for its novelty.

Several collections of foliage and flowering plants were shown. Messrs. Lee, of Hammersmith, had in their's Hedera tulipiferum and Cyathea Smithii, the handsome lively green fronds of which were seen to great advantage between the more sombre foliage of a fine *Alocasia metallica* and a handsome specimen *Epacris grandiflora rubra*.

Mr. Williams, of Holloway, also exhibited an excellent collection, in which was a lovely plant of *Cattleya Skinneri* in full bloom, and handsome plants of *Cordyline indivisa*, and *Gleichenia dicarpa*, and *Cyathea exoelsa*. He had besides Azalea Empress Eugénie, which, though a handsomely-shaped plant, and well covered with bloom, had lost many of its flowers, probably from rough carriage.

Good collections were likewise exhibited by Mr. Bull, Messrs. Henderson & Co., F. & A. Smith, and Mr. Cross.

Of other objects exhibited, collections of Amaryllids came from Messrs. Cutbush and Mr. Parker, of Tooting; British Ferns from Messrs. Ivery and Miss Clarkson; and from Messrs.

Perkins and Sons, of Coventry, *Verbena Lord Leigh*, with large trusses of crimson scarlet flowers with a white eye, and which are well represented in the *Florist* and *Pomologist* for March. The same firm had likewise a pretty Cineraria called Rev. S. Widdrington. Stands of cut Camellias were shown by Messrs. A. Henderson & Co. and Messrs. Lee; and of Pansies, among which were some pretty dark selfs, by Mr. Bragg, of Slough. A batch of variegated Geraniums, as Sunset, Mrs. Pollock, and Countess, were shown by Messrs. E. G. Henderson & Son; also *Coleus nigricans*, with blackish-purple foliage; *Genista prostrata*, a handsome trailer, with yellow flowers; and *Cupressus Lindleyana*, with white variegations. Mr. Williams also exhibited *Phalænopsis Schilleriana* and *amabilis*, *Dendrobium aggregatum majus*, *Tradescantia odorata*, with dark red leaves, somewhat resembling those of *Dracæna ferrea*; a species of *Aralia*, with long, narrow spiny leaves of a blackish-green, and blotched at the spines with paler green; the variegated *Aralia Sieboldi*, *Gleichenia dicarpa*, and some other plants. Lastly, Mr. Bull, of Chelsea, had a large batch of seedling Zonale Geraniums, among which were several pretty unnamed varieties, of the merits of which we shall doubtless hear in due time, and several new Petunias, likewise unnamed; whilst Mr. Paul had *Magnolia Linné*, with large flowers, rose tinged with violet on the outside.

ENTOMOLOGICAL SOCIETY'S MEETING.

THE March Meeting of the Entomological Society was held on the 2nd inst., F. Smith, Esq., the President, being in the chair. The Secretary announced a considerable list of donations to the Society's library, from the Royal Society, the Entomological Societies of France, Stettin, and Vienna, the Society of Arts, the Royal Society of Nassau, &c., including an extensive series of the "Annales" of the French Entomological Society.

A number of minute species of British Rove Beetles (Staphylinidæ), belonging to the genera *Mycetoporus*, *Bryophorus*, and *Homalota*, were exhibited by Mr. G. R. Waterhouse, with relative notes and descriptions.

Professor Westwood read descriptions of two new Australian species of Lucanidæ, one in the collection of the British Museum, and the other in that of Dr. Howitt, who had forwarded a very beautiful drawing of it for description.

Mr. F. Bond exhibited a species of the true *Polyommatus Dorylas*, one of the small blue Butterflies which, although long ago figured by Lewin as a British species, had for many years past been rejected from the British lists as a doubtful native. Mr. Bond had received it as a variety of *P. Adonis*, taken with other insects in the west of England. The name of *P. Dorylas* had also been misapplied by Leach to the common blue Butterfly, *P. Alexis*.

The President read a memoir on the various species of Honey Bees exhibited, together with their nests and honey, in the Brazilian Court of the International Exhibition of 1862. Although the European Honey Bee, *Apis mellifica*, had been introduced and become naturalised in North America, no other species of *Apis* was indigenous in the New World; but in South America their place was taken by stingless Bees, composing the genera *Trigona* and *Melipona*, to which another genus had been added by Saint Fargeau under the name of *Tetragona*, but this genus was not considered by Mr. Smith to be tenable. All these South American Bees are stingless. They vary very considerably with reference to the quality of the honey which they make; and Mr. Smith, by an examination of the organs of their mouths (four only of the species having toothed mandibles), showed that the different species must necessarily be appropriated to very different classes of flowers. No fewer than 120 species of these American Bees had been described; and in the collection exhibited in the Brazilian Court, eleven out of the fourteen species of *Trigona* were new to science, as well as both the species of *Melipona*. It had also long been affirmed that several species of Wasps of the genus *Polybia*, including the *Licheguanus* Wasp were honey-makers, and several species of this genus were contained in the collection; but Mr. Smith, from an examination of their nests, appeared to doubt whether they were really collectors of honey, but thought they were rather robbers, which had stolen it from the nests of *Melifera*.

D. MOORE, ESQ., PH.D., M.R.I.A., &c.—It is with very sincere pleasure we learned that Mr. (now Dr.) Moore, the very

able and much respected Director of the Glasnevin Botanic Gardens, has had the degree of Doctor of Philosophy conferred on him by the Senate of the University of Zurich, the Athens of German Switzerland. Dr. Moore has been selected for this by-no-means common honour, by reason of his many and valuable contributions to the advancement of the natural sciences, more especially in that whose fair domain it has been his privilege to put the sickle, and garner a plentiful harvest.—(*Dublin Agricultural Review*.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE advantage of applying manure in a liquid state to kitchen-garden crops is so great, that it becomes an important duty to see that none is wasted. A tank in the dungyard or frame-ground would be most useful, and into this tank should be conducted all the drainings of hotbeds, heaps of fermenting dung, green refuse, &c. This will form an excellent dressing for Cauliflowers and Celery, for pouring over Sea-kale and Asparagus beds, Artichokes, and a diluted portion over the roots of Peas in dry weather. Indeed, almost every kind of crop will be benefited by it when in a growing state. None, therefore, should be wasted—a waste which, by the way, is far too common even in this enlightened age. It is grievous to see all the drainage of dunghoops running away and finding an entrance into the earth wherever it can. Sooner than allow this it would be advisable to dig a hole to stop it, if time could not be spared to carry it to the kitchen garden to make the Cauliflowers larger and whiter and the Celery finer and crisper. *Beet*, Silver, sow where it is required. *Broccoli*, make a sowing of the various winter and spring varieties. *Celery*, attend well to the pricking-out of the early sowings, and sow more, both on heat and in the open ground, for middle and late crops. *Celery* is best if kept in a rapidly-growing state, the manure to be rich and to have frequent applications of liquid manure, with a small portion of salt dissolved in it. *Cauliflowers*, keep the surface deeply stirred amongst the open rows, and look out for slugs. Continued hoeing and surface-stirring is a great disturber of such vermin, and will now be required for all kinds of advancing crops. Earth-up those which have stood the winter beneath hand-glasses. *Cardoons*, the seed may now be sown in trenches, where the plants are to remain. The trenches to be about 4 feet apart, and a few seeds dropped in at intervals of 18 or 20 inches. See that *Chilies*, *Capsicums*, *Basil*, *Tomatoes*, and *Knotted Marjoram* are in a proper state of forwardness for planting-out at the proper time. *Carrots*, the seedlings just coming up, as also the seedling *Onions* and *Parsnips*, to have the teeth of an iron rake passed through them to loosen the surface. *Kidney Beans*, sow in a box of sandy soil placed in a cold pit or other convenient place for protection, to be transplanted after a time. *Potatoes*, water and earth-up those in frames. If the main crops are not yet in, lose no time in getting them planted. *Nasturtiums*, sow some seed at the foot of a fence where the plants can do no injury by their rapid growth. *Savoy*, another sowing may be made for late crops. The present weather is very favourable for getting in crops where the soil is of a stiff wet nature, and it will generally be found that by waiting till the ground is in good tilth, the crops are equally early and far superior to those sown when the soil was saturated with wet. As the heads of *Broccoli* are cut remove the stumps, as they only harbour slugs and snails.

FLOWER GARDEN.

Make another sowing of hardy annuals on the borders; at the same time sow a little of each in the reserve-garden to supply vacancies in the summer. All empty flower-beds to be frequently forked over during this month and the early part of next, and add some charcoal or charcoal dust, especially if the soil be stiff; if neither of these can be had, use burnt soil as a substitute. See that *Fritillarias* and *Narcissi* are properly attended to as regards staking and tying. The daisy-rake will now be required upon the lawn once a-week. Proceed with the planting of hardy climbers against walls, trellises, and verandahs. Select some of the most showy species—as *Wistaria*, *Bignonia*, *Caprifolium*, *Clematis*, *Tecoma*, &c. If it is desirable to have some disagreeable object hidden from view, the following *Roses* are suitable for the purpose—viz., *Rampant*, *Donna Maria*, *Triomphe de Bolwyler*, *Madame d'Arblay*, *Garland* (Wood's), *Queen of the Prairies*, and *Baltimore Belle*; to be turned-out of pots at this season. The

above *Roses* are rapid and strong growers, and abundant bloomers.

STOVE.

Make cuttings of any stock that is wanted whilst the propagating-frames are at work, not forgetting the old *Vincas*, the *Thunbergias*, *Plumbagos*, *Justicias*, &c.; these, although old-fashioned, contribute much to the general effect. Pay due attention to watering, shifting, stopping, &c., of stove plants in general. See that growing *Orchids* have abundance of atmospheric moisture, with a circulation of air in the morning, shutting up close betimes, and taking care to observe moderation in the use of fire heat, in order that a pure atmosphere for the night may be insured. Growing *Dendrobiums* will now require liberal supplies of water, and let plants on blocks be frequently syringed.

GREENHOUSE AND CONSERVATORY.

With the increased circulation of air, which the present mild weather will sanction, there will be a more evident necessity for increasing the supply of water to repair the loss which must ensue from a rapid evaporation. During strong solar light the paths of the houses may be damped, which will produce a gentle moisture very grateful to exhausted plants, many of which, having lately been shifted and made some little growth, will suffer from any deficiency of moisture. Proceed with the staking and tying-out of plants requiring such assistance, but if our former directions were carried out relative to growing plants with short-jointed wood, stakes may be generally dispensed with; but some will be necessary to give the plant its desired shape. Turn each plant frequently round that it may not become one-sided. Planted-out things will require thorough waterings. The larger specimens in tubs or pots, if any, to have a liberal supply if the drainage is complete. This is the period for the use of liquid manure, but take care that it is clear and not over-strong. Large *Orange trees* are very fond of it.

PITS AND FRAMES.

These will want, not only daily, but hourly attention. Propagating, pricking-out, potting, hardening-off, with shading, syringing, &c., will be the order of the day for three weeks longer, by which time a thorough supply of stock will be provided for both summer and winter for out-of-doors and in-doors.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

STIRRED the soil among *Cabbages* and *Cauliflowers*, and soused with manure water. Dug, trenched, and turned over vacant ground for *Peas* and late *Carrots*, and main crops of *Beet*, &c., which will be sown about the end of the month. Sowed succession *Turnips*, *Radishes*, &c., and attended to things in general as described in late weeks. Looked over and nipped-in *Cucumber shoots*, and thinned fruit. Sowed rows of Dwarf *Kidney Beans* in front of orchard-house, where *Parsley* stood for the winter. Sowed others in boxes and pots for transplanting under protection. Sowed *Scarlet Runners* also in boxes for transplanting, as they thus fruit rather earlier. Planted out *Broad Beans* from boxes, and sowed others, and scattered burnt earth over seed-beds and young plants, to keep worms and slugs from them. Planted more *Lettuces*, &c.

FRUIT GARDEN.

Regulated *Strawberries*. Planted out a lot of those that had been forced earliest. Pots being an object, they had been turned out close to a north fence, the balls placed close together, and a little rough leaf mould strewn in between them. They are now being planted in a well-dug border, but without breaking the balls at all, the earth being placed firmly against them. From such we generally get good gatherings in September and October, and heavy crops the succeeding year, when the plants are past their best, the second summer's crop being inferior to the first. Being scarce of frames, set lots of plants in the orchard-house to succeed those taken from the forcing-houses and pits. The earliest vinery is now of no use for such a purpose, there being too much shade to permit of flavour to the *Strawberries*. If the plants are brought on a little gradually they do better than when taken from out of doors into a forcing-house at once. Thinned *Grapes*, disbudded *Peaches* in houses, and thinned fruit. In disbudding prefer doing it at different times, instead of leaving only the number of shoots at once, as that in our opinion, though involving less labour, has a tendency to arrest

root-action at a critical time. Used all the thinnings, bruised, put in a tub, and covered with boiling water, to syringe the trees with when the water was cool, poured through a cloth and other water added; so that a bushel of such shoots bruised, and that is easily done, would make about eighteen gallons of cold weak *prussic-acid tea*, which no insects like, and which at that strength most stone fruits like over their foliage, and the houses after the syringing will smell as sweet as a confectioner's shop. Watered Figs, and stopped and regulated shoots, and will soon have to move the Scarlet Geraniums beneath them. Planted out more Melons. Potted Vines in pots, &c. Those who grow Pines must water carefully; and instead of overwatering, it will be best to shade in these very bright days, so apt to be succeeded by dull, cloudy, and wet ones. Extra moisture at the roots is apt to make fruit showing come deformed, and with huge unwieldy crowns.

We notice in page 265, first column, a good plan for getting good *Grapes in a frame*, by Mr. Keane, and we have often been surprised it was not more adopted. When we used to try it we did not make any slit in the boxes to let in the Vines, but merely brought them in through the dung beneath the bottom of the box; and if a lot of roots ran ultimately into the dung from the stem, we did not trouble ourselves in removing them. Also, we generally allowed the stems to lie either close to or only an inch or two from the dung, before they were broken 2 or 3 inches in length, and then by some simple means, as sticks or trellis, they were elevated within 12 or 14 inches of the glass. When the bed was covered with slates or tiles, these were painted with sulphur and lime, if the foliage was at all thick, and with sulphur and a little soot if the foliage was rather thin. The stems not in the box were wrapped round with haybands to prevent sudden extremes of temperature.

We have also seen good *Grapes* against a wall by placing sashes that were to spare against them, something in the Paxtonian fashion, and perhaps the very best were thus managed. The wall was about 7 feet in height, the Vines grown on the long-rod system—that is, the stem that fruited was cut out every year, and a young one grown in summer to take its place. Unless in very severe weather the Vines were exposed all the winter. In the end of February they were pruned, painted with sulphur, and laid down at the foot of the wall, with just a slight sprinkling of straw over them, which kept them from frost, and also tended to make them come later, and induced them to break regularly, which they seldom did until the end of April. They were then fastened to the wall, and the sashes put against them. This also was done in a very simple way. Stout iron brackets stood out a foot from the coping of the wall, and to these were screwed a batten of wood all the way, $2\frac{1}{2}$ inches square. To that batten in turn the tops of the sashes were screwed by two screws in each sash; this left room between the batten-slip and the wall of more than 9 inches, in which a nine-inch board, lying flat, moved easily, and the space being 30 feet in length, two fifteen-foot boards just filled it. There were no hinges or anything of the kind; but a small ladder stood at each end, and the board could be moved to give an inch of air, or set up against the wall to give fully 8 inches, just as was desirable. The bottoms of the sashes rested on a flat rail supported by posts 9 inches from the ground. When the sash was set on the rail, a stout nail in the rail in front of the sash kept it in its place. The loose board did for air in front, but unless in very hot days was seldom used. If the house were shut up at night, a very little air was always given early in the morning, to prevent the heat accumulating too fast, and much of the success we attributed to the comparatively cool temperature at night, and the high temperature, but with air, in hot sunny days. We recollect seeing the thermometer between 90° and 100° , and yet the Vines and Grapes stood it well. The temperature at night would range from 45° to 60° at these times. The one end was covered with stout calico, and a door, also covered with calico, instead of wood, was at the other end. The sashes were used for salads and bedding plants from the end of October to the end of April. The rail for the sashes was $3\frac{1}{2}$ feet from the back wall.

ORNAMENTAL DEPARTMENT.

Rolled lawn preparatory to mowing. Would like to cut *Box-edgings*, but will put the cutting off for a time, fearing we yet may have a frost, as, when fresh cut, Box turns black and looks unsightly for some time afterwards. Dug over beds as opportunity offered, doing this roughly in all cases where planting and sowing were not contemplated. In beds and borders, where planting and sowing were to be done, dug and made fine. In borders, regu-

lated herbaceous plants; planted Heartsease, Pinks, Carnations, &c.; examined Hollyhocks and Phloxes, firming the earth about them, and placing round them some burnt rubbish to keep slugs, &c., at a distance. Ranunculuses, Anemones, &c., should be well firmed round the necks of the plants, and protected from deluges of rain and sharp frosts if they come; and the same may be said of Hyacinths and Tulips. To have fine strong flowers of Ranunculuses, a good plan, after firming the soil round the plants and the ground all over, is just to stir it half an inch deep or so, and then cover the ground with half an inch of fine riddled old cowdung, which will keep the tubers moist and permit of nourishing waterings when rains come or the watering-pot is used. Most of the hardy annuals may now be sowed. In cold soil it will be as well to defer Mignonette until towards the end of the month; but if wanted early out of doors, a lot may be sown in pots to be transplanted, placing these pots under protection. All the half-hardy annuals used for bedding should also now be sown in a slight hotbed; or the bed may be as much as 18 inches deep, with 3 inches of old dung on the top, and as much of fine soil to sow in if you do not have glass to cover with. Stout calico is a capital covering for such a purpose, but it is dear this season. We had a piece not stout the other day, about $1\frac{1}{2}$ yard wide and $10\frac{1}{2}$ d. the yard run, which not so long ago might have been had for 5d. or 6d. per yard run. We trust that calico will yet be more reasonable, and that more for the sake of our Lancashire friends than even gardening purposes, though for the latter it is very useful for makeshift workings at this season, as nothing can equal unbleached coarse calico for hardening-off bedding plants. Another substitute will, no doubt, be obtained when thoroughly demanded. Frigidomo, 2 yards wide and 1s. 6d. per yard run, is a good protection; but it is too thick and dingy for hardening-off bedding plants. Many half-hardy plants will lift in patches from such a bed as the above, hardly feel the moving, and do much better than those sown in pots and coddled in houses.

We must stop, and wish we could stop or find more room for cuttings of bedding Geraniums—among others, Cloth of Gold, which seems to strike very fast; Ageratums, Verbenas, &c., which must be done now wholesale. Have filled all our earth pits with bedding plants, and have nearly filled the old cabbage ground with wide Celery-trenches (5 feet), and these, too, are being filled with Geraniums planted out of boxes or turned out of 60-sized pots, that the pots may be washed and filled again with smaller things, so as to give them a better chance. Planting-out at once is the best for all things that make bunches of fibrous roots. Such plants as Verbenas we plant separately early; but after this season those struck in half-circle drain-tiles are turned out of the tiles, and planted in rich soil just in lumps as they are. By this means no check is given, and when taken up to plant they separate easily, as the fresh roots do not get too far away. This is also a good plan with the Variegated Alyssum if the young plants cannot be kept in pots. If you turn out little plants into a temporary bed as a Celery-trench, they will rise badly, because the roots may wander too far; but when pots of cuttings, or tiles of cuttings, are turned out, and planted in a piece as stated above, the new roots do not wander so far from home, the plants grow freely, and when raised up with a fork in a piece they will plant-out nicely, and scarcely show a flag of distress. If we can spare a frame or two we will make-up a slight hotbed for Verbena-cuttings, cover with 3 inches of rotten dung, 2 inches of rough riddlings of soil, and 2 of finer on the top, with half an inch of drift sand over all, plant the cuttings about 2 inches apart, and in May these would rise with nice balls of rough soil and dung adhering to them. Such methods might not do in a commercial establishment; but something of this kind must be done when the most is to be made of limited means.—R. F.

ERRATUM.—At p. 266, second column, 19th and 30th line from top, the words "pit" and "pits" in the respective lines should be "pot" and "pots."

TO CORRESPONDENTS.

AZALEAS DYING AFTER FLOWERING (J. McN.).—As a precaution, it would be well to be certain that the plants are thoroughly soaked to the centre of the balls, either by placing the pots for half an hour in a tub of water, or making a number of small holes a good depth into the soil with a stout pointed wire, and then watering. The plants should also be kept cool for a week or two after flowering, and be syringed overhead.

DRAWING FLOWER-SEEDS (W. W. H.).—There is no book upon the subject. We hope to begin publishing a series of communications upon geometrical drawings, &c., next week.

APPLE-TREE SHOOTS DISEASED (P. J.).—The roots have descended probably into an ungenial subsoil; and this, combined with the deficient warmth of last summer, has caused the outbreak of canker and the shrivelling in the shoots. If the subsoil is heavy or wet it should be thoroughly drained; but whatever the subsoil may be, we recommend a trench 2 feet deep to be dug on one side of each tree, and then the earth picked away from beneath it, so that all descending roots may be cut through. Then return the earth, and keep the surface slightly manured and mulched in summer to induce the roots to grow nearer the upper stratum of soil. Do not let this be dug, for such digging compels the production of roots lower down.

PRIZE-TAKING GARDENERS (A Young Shoeman).—Never mind what "T. R." or any one else says about gardeners exhibiting, but go on. Everybody writing in favour of his hobby is liable to use strong expressions without intending to offend.

STALKS AND FRUIT OF GREEN GAGES TURNING YELLOW (Amateur).—There is no doubt that the roots have descended into a soil that is ungenial. Serve them as we have recommended another correspondent to serve his Apple trees, but do not do so until the autumn. At present the best treatment will be to remove the soil until you come down to the roots nearest the surface, and cover these with some thoroughly decayed manure, and water with tepid water. Cover the roots thus a distance of 3 feet from the stem all round. The absence of bees will not injure the crop.

BUDS OF APPLE TREES DEFORMED (Mrs. W.).—The information you now send fully accounts for the diseased and decrepit state of the trees. "Sub-soil yellowish gravel; ground has been cropped close up to the very trunks of the trees." The surface roots have consequently been destroyed, the trees compelled to root down into the gravel. The remedy is precisely the same as we have recommended to-day to another correspondent whose Apple trees are affected in a somewhat similar way. You have justly abolished the cropping, and you must now cut away the descended roots and encourage surface roots. The deformed shoots we should prune away by degrees.

FLOWER-GARDEN PLAN (Sarah).—If Tom, Jack, or Harry had sent us such a plan, we should have been tempted to engage it, just to show what an amount of labour and worry some people would take to make a lot of all sorts of figures in a flower garden, some of them hideous enough, and having no possible connection or balancing with each other. There is scarcely a figure in the two large groups but might be surpassed by another still more ugly, and that without disarranging in the least the general effect as a whole. As it is "SARAH" who asks our advice, why we can only remind her that disjointed variety is fatal to beauty, and that the planting intended will be far superior to the forms of the clumps, and the effect will be far better than the colouring with which she has kindly given us an idea of what the appearance will be. We would recommend her to carry out the proposed planing this year, with such little modifications as may be suggested; and next year, after reading all the notes on flower gardens, cut up her large flower garden into several distinct groups, so as to give to the whole more light and shade, as well as distinct features. At present there are two groups, one on each side of a walk to the greenhouse, which, with the exception of the centres, seem to have little similarity or balancing with each other, and yet our correspondent "SARAH" has fair ideas of grouping and balancing. Thus on the left-hand side there is a centre of a large figure that might be considered a star with large rounded points, and that is to be filled with mixed Verbenas, which scarcely any planting can make look ill. Then round that there are three circles and three large oblong beds alternately, which also will, no doubt, look well. The three oblongs, all varying in form, but near enough to ovals with blunt rounded ends to suit our purpose, are thus planted:—The side next the Verbenas blue Lobelia, the centre Christine Geranium, the other side Lady Plymouth, white variegated-leaved Geranium. The colours of the bed put down are blue on one side, pink in the middle, and white on the other side. A good friend told us the other day that really we must put a bridle on our fancy—the illustration of the pony chaise in the sketch of Straffan was really outrageous. Well, let him and "SARAH" settle it between them. There, as anybody may see, is the pink body of the pony chaise with one wheel charmingly blue and the other wheel as delicately white. With this exception the balancing system is pretty well maintained, 10 and 12, 9 and 13 doing well as counterparts, though, from the large size of these and the remaining beds, they would have done well for broad edgings. We also think 14 should balance with 8. On the right side of the walk the centre and the six beds round it are the same as on the left side; but here balancing ends and the beds opposite each other on the two sides of the walk come in as contrast rather than in uniformity, as Trentham Rose and Heliotrope, Manglessi Geranium and Purple King Verbenas, &c. We find no fault with this: it is just the question of the pair of horses—matched or dissimilar? We do not know the size of the beds, but we judge they must be rather large, and therefore such as would be improved by edgings, and pretty broad ones. On the whole, though convinced that "SARAH's" labours are greatly increased by the form and arrangement of her beds, we have no doubt the effect of her planting will be far superior to the colouring on paper.

SEEDLING CINEARIA (A. K.).—Showy, but nothing more, so far as we can determine from two withering pips. The truss and habit of the plant have to be considered.

DENDROBIUM NOBILE (A Subscriber).—Too much dryness at the roots and a moist warm atmosphere are apt to make this Dendrobe break, as you describe, "freely along the bulbs, but not from the bottom." If you dislike the appearance, you had better take the pieces off and form with each a fresh plant. For Mignonette Trees, see article in another page.

BURNT EARTH FOR VINE-BORDERS (Q. Q.).—The rougher part of the burnt earth would answer well for the Vine-border. A few bones in addition would be advisable, as the burnt earth will act chiefly in a mechanical manner for keeping the soil open.

PLANTS BETWEEN ROWS OF GLADIOLI (Idem).—Why should you have plants between rows of Gladioli at all? The Orach will answer as well as any other, and by pruning and nipping you may have it just any height you please, from 6 inches to 6 feet.

GOLDEN CHAIN GERANIUM (Idem).—The yellow edge of Golden Chain varies much according to exposure and growth. It is generally nearer three quarters of an inch than one-eighth of an inch, but frequently there is less green than yellow. There is no accounting for such things. With us Brilliant Geranium flowers nicely; but we never have so much white at the edges as many of our neighbours.

CAMELLIA EXIMIA (A Subscriber).—A double-centred Camellia flower is not of usual occurrence, but we have seen two or three similar instances. They occurred, as yours seems to have occurred, on a robust well-grown plant.

FLOWER-GARDEN PLAN (Diffidence).—We will publish a drawing of your plan next week, with a few notes.

VINES THE SEASON AFTER PLANTING (J. C., Halifax).—If not experienced you would have acted wisely to have let your Vines break naturally, merely keeping frost from them, giving them a lift with a little fire heat in dull cold weather in summer, and ripening the wood early by a little dry heat in autumn. We know of no fruit tree so suitable for training under the ridge of a cool greenhouse as a Vine. If you fancied such a fruit, however, the Passiflora edulis would do very well, and would fruit in the second or third year. The fruit is purplish-coloured, and about the size of a hen's egg. Some people are very fond of the fruit, as it is very peculiar in flavour and luscious. We think Hentfrey's "Rudiments of Botany" would suit you to commence studying.

VINES FROM EYES AND FROM LAYERS (W. M.).—We know of no superiority possessed by Vines raised from eyes in comparison with those raised from layers. They are usually raised from eyes or from cuttings, because more can be so raised from the shoots pruned off, and because it is not often that layering is convenient.

PORTABLE MANURES (J. Picard).—As a general manure guano will suit you. Rake your mossy lawn, and give it a dressing with finely-sifted coal ashes and a little cubic petre. For a kitchen garden you will require more than one package, and had better send a post-office order. A manual will shortly be published at our office, entitled "Manures for the Many," which will give instructions for their application.

TROPEOLIUM SEEDLINGS (T. C., Yorkshire).—Both are too ragged to be of much use while there are so many good forms of the Lobbianum breed. No. 1 is pretty, and from your description of its habit may look very well in a bed; but of that, of course, we cannot judge.

TOM THUMB GERANIUM LEAVES TURNING WHITE (A. R.).—We fear your plants receive too much water, or are in the shade too much. Many of the Tom Thumb breed of Scarlet Geranium become blanched-looking in the foliage in winter, but recover as the spring advances, and we hope yours will do so also. Keep your plants more dry, and if they have been in the shade remove them gradually to the light; and if you keep the place a little warmer it would be better. We fully expect shade and moisture are at the bottom of the evil, and that a contrary course will remove it.

TWENTY HARDY ANNUALS (A Subscriber).—The following will succeed well in most places if sown on an open border:—Clarkia pulchella, Erysimum Peroffskianum, Iberis grandiflora, some Larkspurs, Leptosiphon densiflorum, Schizanthus pinnatus, Viscaria oculata, Saponaria calabrica, Calliopis (may be late), Collinsia bicolor (good and hardy), Nemophila insignis, Convolvulus minor, Stocks of Ten-week breed, Marigolds of the orange or old English class, purple Jacobaea, some Lupinauses, and Enocheras or Godetias; and if the soil and season be favourable Asters and Chrysanthemums do pretty well sown in the open border. To these we may add Sweet Peas, Mignonette, and Nasturtium, all useful annuals in their way.

NAMES OF PLANTS (Quercus).—1, Rhamnus alaternus; 2, Amelanchier botryapium; 3, Ruscus aculeatus; 4, some Cypress, not to be recognised from a scrap. (An Old Lover of Flowers).—Your "Australian Lilac" is Hardenbergia monophylla, formerly Kennedy, and in an early volume of the "Botanical Magazine" is drawn and named Glycine bimaculata. (A Subscriber).—The flowers of Rhododendron Maddenii are white. The leaves you enclosed look like those of R. arboreum. (A. R. C.).—Habenaria elegans. (H. H. W.).—1, Pilea serpyllifolia; 2, Onoclea sensibilis, a hardy, not a stove Fern; 3, Woodwardia, or Doodia media.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE POULTRY CLUB.

To make a good donkey race every competitor should ride his neighbour's donkey; and if the proposed rules for judging are carried out, we would suggest that every man's pen shall be judged by one of his opponents. Eye is no longer required; gift is all moonshine; practice is nothing. There are the rules, and a first-prize pen must possess the qualifications that are put down. No. 6 condemns No. 5 in Hamburgs because the tail is not pencilled, and No. 5 condemns 6 because the hackle is spotted. No. 3 condemns 4 because there is a loose comb, and No. 4 condemns 3 because the pike is down instead of up. This is not so ridiculous as it may seem. Rules are to do away with discretionary power and awards, which form the groundwork of all complaint, and to inaugurate the golden age by informing exhibitors what they must breed, and by what rules they will be judged.

There will be something quite touching in the resignation with which a whole class of exhibitors will submit to be told that none of their pens are perfect or come up to the standard as settled by the Club. It may be that one ill-conditioned person will ask to have the money returned, as no prizes are awarded; but, of course, an appeal to his better feelings will cause him to admit the injustice of his conduct. How beautiful the spectacle will be of a score of disqualified exhibitors all perfectly satisfied, studying the points, admitting their shortcomings, and wondering at the folly that permitted them in past times to take prizes they did not deserve!

What a good example will be set by the President, Secretaries, and Council if they give the cups they have gained to decorate

the club-room, and to show their sincerity. Judges and exhibitors will be all agreed; the latter will not wait to have faults pointed out—they will proclaim them. When things are properly understood, and the rules are properly digested, it will not be difficult to find exhibitors who will judge their own classes. Fancy, at a small exhibition, one of those little Poland or White Cochins where there are three competitors. The three walk gently up to the class, together they examine each other's pens, there is a short reference to the book; conviction steals over them, and the senior shakes his head, while he says, "Brothers, brothers, we are all wrong." The advantage will be immense; no erratic judgments; no possibility of crotchety arbitrators; no generalities to shield ignorant or knavish awards; all fair sailing according to the book. Then, after a time, knowledge will be diffused; since all that is necessary can be learned from a book, all will be alike well informed, and the exhibitor with the Judge will stand in the position of the 'coon with the Curnel. "Don't shoot, Curnel, I will come down." You need not judge, I will give in. I see I am beaten.—CHITO.

BATH AND WEST OF ENGLAND POULTRY EXHIBITION.

YOUR correspondent "J." in his remarks upon the above Society's regulations as to poultry, forgets the fact that the poultry department is but one of many, and that in the general arrangements of the Exhibition of the Bath and West of England Agricultural Society a necessity exists (under the recent decision of the Council to open five days to the public), for an earlier arrival of the birds than when the Show extended only over three days.

I quite agree with him in thinking it desirable to shorten the period of confinement as much as possible. With this view I have obtained the sanction of the Council to admit specimens as late as Saturday evening, the 6th of June, instead of Friday morning. To accomplish this we shall adopt the system of open judging on Monday, as will be the case in all the other departments. Exhibitors who like to see their own birds judged will have the opportunity of witnessing the duties as discharged by our Judges. I trust, as the system has succeeded so well at Battersea Park and Hereford, it may also in poultry at Exeter. At all events owners will see that their birds are not passed over, and that judges do take trouble to inspect and decide to the best of their ability.

As to the complaint of another correspondent, that many classes are omitted, I can only remark that we have, after ten years' experience, come to the conclusion that it is better to give good prizes to all the leading classes rather than to divide into more numerous and give small rewards to all. Large as £160 seem to our Council—and it is the largest sum given by any agricultural society in either England or Scotland—when divided into smaller sums for the various classes, it is truly not sufficient to bring all to our yard. The Stewards, therefore, determined, whether wisely or not the general public must judge, to leave what I may call the more exceptional classes, most deserving of all support and honour, to the Crystal Palace and Birmingham Shows, that have larger funds to deal with; and to stimulate exhibitors to send us as good an exhibition as possible of classes more generally kept throughout the kingdom.

We have striven in vain for some years past to induce exhibitors to send many of the classes mentioned by your correspondent. I thank him still most heartily for his remarks, and have to the best of my ability done what I could to promote an interest in poultry exhibitions. If he could have sat at the Council Board with me for the last ten years, he would have felt that it is a task of no common labour to induce an agricultural body to give the support which the Bath and West of England Society has to the poultry department. When the Royal Agricultural Society abandoned their exhibitions, their evil example might have been followed; but such, I am proud to say, has not been the case—upwards of £1500 has been distributed during the past ten years.—S. PITMAN, *one of the Stewards of the Poultry Department.*

MALAY FOWLS.

WHEN your correspondent the Dotter at Devizes first made his remark, "Some Malays were there conspicuous by their ugliness," I must confess to a most overwhelming warlike feeling of opposition to one who could thus designate my favourite

breed of fowls; but a little patience, and here comes the good in place of the imaginary evil. Up springs friend Fox, and starts a fine course of inquiry and reply, and consequent information; so that our hitherto-almost-isolated pets are really now making a grand show in the columns of the "Poultry Chronicle," and assuming their true position—viz., important members of the aristocracy of poultry.

In reply to the spirited letter of Mr. J. J. Fox, you give us "your notion of what a Malay should be;" and I feel bound to say that it is the best description I have ever known given—at any rate, it is in strict conformity with my own ideas; and, therefore, it is not surprising that I should dub it *AL*.

Friend Fox says that when doctors differ patients suffer; but differ they will for all that, and Mr. Ballance is not the only one who differs on this subject. In 1860 a Poultry Diary was published, to which was appended, "The proposed basis for uniformity of judgment at exhibitions of poultry, submitted by the Amateur Poultry Society of Dublin," and amongst the rest was the Malay described thus:—*HEAD*, *beak* horn colour; *eyes*, orange red, sunken beneath a projecting brow (we like pearled eyes); *comb*, low and indented; *wattles*, very small, more properly folds of the skin of the throat than wattles; *ear-lobe*, rudimentary; *face*, brilliant crimson; *neck*, orange red; *back*, maroon; *wing*, shoulder maroon, steel-blue bar across; *flight-feathers*, bay; *breast*, black with irregular bay markings; *tail*, scanty, drooping; *legs*, olive brown.

By comparing this with "your notion" and Mr. Ballance's letter, we find that our Hibernian friends differ with us on various points, and are not set on yellow legs. Some of the best birds I ever had or saw had pale olive or willow legs. My present stock have yellows. I should not mind if they were olive. I certainly should prefer pale olive or willow to white.

I cannot agree that legs of any other colour than yellow could not be shown in a Malay class. I have seen pale willows take a Birmingham first prize.

I also feel assured that a true Malay, however fine in feather, ought to have the "red jacket" bare and exposed fore and aft, as mentioned in your "notion," and I really think that of late years more than one exhibitor has tried to breed for more feather than the Malay fowl should have, because other persons who have not perfectly understood the breed have looked upon this real and essential property in a wrong light, and have given encouragement to the more full-feathered specimens.

Mr. Ballance fears that some judges have lost sight of "perfection of plumage, and have awarded prizes to birds of good blood though wretched in feather." I say with Mr. Fox, "I never did and I never wish to dispute the decisions of Judges;" but I really do venture to think that when mistakes have been made, it has more often been in favour of the over-feathered sort than their more scanty and close-cut brethren; and I quite agree with you that there are but few judges of Malays in England.

I cannot exactly understand your correspondent the Dotter at Devizes. First he says they were conspicuous for their ugliness; secondly, he admired Mr. Fox's as much as any; thirdly, some young birds provoked him because they had not the brighter colours of adults; and fourthly, Mr. Fox's birds were too handsome. But, never mind, he winds up with a warm eulogium on the characteristic of the Malay, "especially the featherless strains;" and glowingly describes his peculiar defiant air, and how cool the bold fellow takes any endeavours to intimidate or ruffle him, a compliment none the less sweet because well merited. For this I, as the friend of Malays, sincerely thank him, and beg to assure him that all the overwhelming warlike feelings are "abandoned, buried in oblivion," &c.—JOHN RUMERY.

P.S.—When the Poultry Club have a wish for subscribers, it is to be supposed they will advertise where circulars, &c., are to be obtained.

TOMTIT AND HIS ASSOCIATES.

Of the Tit tribe there are seven species natives of these islands, which may be briefly enumerated as follows:—

First, the Great Tit or Tomtit, known also by the names of Ox-eye, Joe Ben, Chinker Chinker, and Billy Biter. He has a very dark bluish-black head, whitish cheeks, yellowish breast with a black stripe running down the throat, and the upper parts of the body are bluish-grey.

The second is the little Blue Tit, known also by the appellations of Billy Blue, Blue Cap, Titmouse, or Nan. This species is much smaller than the before-mentioned: it is devoid

of the black on the head and throat, but has some fine azure blue on the head, the general plumage being of a dingy blue colour.

Third, the Coletit. This bird is about the size of the preceding, but is not nearly so blue in plumage, being more of a brownish-grey. The head is black. There is some white about the cheeks, and a whitish mark divides the black at the back of the head, and by which it may be readily distinguished from,

Fourth, the Marsh Tit. This bird is intermediate in size between the first and the others; it is slighter made. The head is all black, the general colour being brownish-grey, so that it bears considerable resemblance to the Black Cap Warbler; and it is not improbable that this likeness may have caused this bird to be blamed for the other's fruit-eating.

The fifth is the Long-tailed Titmouse, sometimes also called Bottle Tit, on account of the form of the nest which it builds. It is the smallest of our Tits, pied black and white, with a very long tail in proportion to its size. They are very active little birds, and usually live in small communities through the winter, the few that survive pairing-off in spring.

The two remaining species of Tits—namely, the Bearded Tit and the Crested Tit—are very local birds, nor do I think they are sufficiently common to require the gardener's notice; and, as I have not seen them alive, I can give no account of their habits.

Of the five species previously enumerated, their habits are so much alike that one description will serve for all.

I am well aware that with many fruit-growers and gardeners there is a strong prejudice against the whole fraternity of Tits; and I must therefore be somewhat particular in describing their habits. Let us suppose a pair to have eked out the scanty fare of the cold winter months, when they had to subsist principally on the insects which they could pick out from their retreats, among the moss, in the cracks of the bark of trees, or in the chinks and holes in walls and such-like places, by picking up a few stray crumbs or bits of fat, overhauling the horse-droppings on the road, or even by a sly visit to the butcher's premises, in order to pick a little suet. Having thus escaped starvation the pair betake themselves to an orchard, and here they set diligently to work to pick off the eggs of moths that have been laid in rings round the twigs, and which are ready to hatch as soon as the leaves are forward enough to provide the young caterpillars with subsistence. There is also a weevil that lays its eggs at the base of the buds or among the scales, and the Tits are busily engaged hunting the young larva as soon as it commences eating the bud; it is now that the ire of the gardener is first raised against the industrious Tits for pecking the buds, though their doing so is only to feed on the destroyers that have been overlooked by man, but not lost sight of by the birds, and which if not killed at this time would do irretrievable injury to that crop of fruit, besides becoming the progenitors of devastating thousands in years to come.

The buds in spring being fairly opened, the yet tender green leaves are preyed on by all those caterpillars hatched from the eggs overlooked by the Tits, and these now form their chief food; of which also the Sparrow, Chaffinch, and several other birds partake largely, particularly during the time they are rearing their young ones. As summer advances the old ones, followed by their merry troop of young, fly from tree to tree picking-out all they can find that have now spun their cocoons or laid themselves up for the chrysalis state; they search, too, for those caterpillars that wind themselves up in the leaves, small beetles, weevils, earwigs, and other insects, either in the egg, grub, pupa, or perfect state. Whenever they can find them they eat them up, and thus prevent their doing any further injury, giving them no chance of bringing forth a numerous progeny, which they assuredly would do if left unmolested. There is scarcely a tree but has some insect that preys on its leaves, fruit, or even the wood. Is it a weevil that deposits its egg in the young nut while the shell is soft? Tomtit is there to pick out the egg, to catch the old insect, or, when the nut having grown, the maggot grown too by feeding on the kernel, and boring for himself a way out that he may transform in the ground, Tomtit is there to look for him; but, being in such suspicious proximity, he is often accused of doing that which he has tried his best to prevent. There are other insects that deposit their eggs in the young Plums, Pears, and Apples. All fruit-eaters must be well acquainted with the excavations and borings of these depredators, and Master Thomas Tit is very fond of their plump and well-fed carcasses; yet, when he attempts

to enlarge the hole to fetch them out, and thus prevent their ever being the parents of another generation, the hue-and-cry is raised, "The Tomtit is pecking my best fruit!" It is a pity he cannot change his name, for at present he has such a bad one that few will believe any good of him, and all manner of damage is laid to his charge, of which, as generally happens, if properly looked into he would be found innocent.

But time flies, and I am already taking too much space. As the nights become chilly and insects are less plentiful, he will come to the garden for Sunflower and Poppy seeds, and during the cold of winter he will exhibit his predilection for insect food even under difficulties, by tapping at the entrance of the bee-hives and picking up the bee that ventures to answer his summons. But are the Tits all to be persecuted for doing this that may be easily prevented? A little piece of netting stretched in front of the hives will keep him at a proper distance; while gathering the seed when ripe will prevent his appropriating them to his own use. As to his bud-pecking and fruit-eating, it is far too insignificant in comparison to the immense good this tribe of birds do, could it be but viewed in its true light, and without prejudice; for, if these bud and fruit-destroying insects were not killed by the birds, how much fruit might we expect to ripen? I fear the quantity is now much less than it might be.—B. P. BRENT.

WHICH OWL DESTROYS GAME?

YOUR correspondent's excellent remarks upon the various insectivorous "Garden Helps" in last week's Journal, contain opinions as to the propensities of the owl which I think will be found to be erroneous.

He considers that none of our owls are destroyers of game. Now, I have heard of the debris of game of all kinds—hares, partridges, &c., being found in immense quantities in the haunts and nests of at least one of our owls. I am not naturalist enough to remember which, but I think it is the brown owl.

If you would insert this, no doubt it would meet the eye of many a correspondent who is in a position to give some interesting information on the subject.—W. H. BEADON.

MEETING OF GERMAN BEE-KEEPERS AT POTSDAM.

(Continued from page 197.)

THE next subject taken into consideration was:—

III. *Of what practical value is a drone-breeding queen in spring?*

Herr Vogel, by whom this question was proposed, introduced it by stating that a drone-breeding queen produced early in spring drones to impregnate any young queens which may then exist, keeps the bees at work, and when added to an artificial swarm, the bees are satisfied, and may even be placed beside normal stocks without returning to their old hive, and her presence encourages them to defend themselves from robbers.

Herr Weitzel on the other hand declared that such a queen has for the rational bee-keeper no value whatever (cheers).

Herr Hubler advised, amidst general cheering, that any one who had a drone-breeding queen should take her between his fingers and mercilessly crush her head.

IV. *Why are artificial swarms to be preferred to natural swarms, and how may the remaining royal cells be certainly and safely used in the same apiary?*

Pfarrer Dzierzon said, "This question presupposed that artificial swarms are, without exception, to be preferred to natural swarms. This, however, I should not assert. One may often do just as well with natural swarms. Artificial increase by means of driving is preferable when natural swarms do not issue in good time, especially in countries with an early pasture, which, however, lasts but a little while; for natural swarms, perhaps, might not issue till about the end of the honey-harvest, and then both young and old must meet the winter destitute of honey. Where, however, the bee-pasturage lasts as late as September—where even swarms which issued in August may still become good stocks, and where also, as is generally the case in such countries, the pasturage lasts a long time, sufficient (perhaps more than one wishes) swarms issue naturally—there would driving be superfluous, and no man of sense will endeavour to attain by artifice what nature gives voluntarily in sufficient quantity."

Pastor Kleine said, "I do not claim any particular advantage for artificial over natural swarms, nor will I allow that artificial swarms are in any respect inferior to natural ones. All depends upon setting to work in a sensible manner—on going hand in hand with nature so as to make artificial equal to natural swarms, and even to secure to them important advantages. It cannot be denied that in bee-keeping, according to Dzierzon, they have obtained a degree of certainty which obviates failure. In respect to the second part of the question, I may be allowed to communicate my mode of procedure which enables me safely to use all royal cells in one and the same apiary. About eight or ten days before I begin to make artificial swarms, I choose one or several stocks to rear young queens. According to the number of begun and disposable queen-cells, I make artificial swarms, inserting brood-combs and giving to every swarm a sealed royal cell, so that it may come into possession of a young queen with as little loss of time as possible. However, I always insert the queen-cell where the bees naturally make their chief seat—thus, at the top or middle of a brood-comb in order that the nymph may not lack the warmth necessary for hatching, even if the bees should not collect themselves about it. Thus it very seldom happens that one of the inserted royal cells fails to hatch. But in order also to provide against this contingency, I always leave in the queen-rearing stocks a few superfluous royal cells, especially those which have been made on the surface of the combs, and the cutting-out of which, moreover, would damage the comb. In order, however, that the young queens confined in them may not be torn out, I protect the sealed cell by means of a very simple apparatus, by a queen-cage, which by its simplicity and practical usefulness distinguishes itself as much from the trap of the heath bee-keepers, as from the Dzierzon queen-cage and the various imitations of it. This queen-cage is nothing but a tobacco-pipe cover made of wire, such as is frequently used by smokers, and which one may buy for a few pence at every wire-worker's. Such a cover I put over the queen-cell and press it into the comb as far as the partition-wall, so that the bees may not be able to gnaw through under the edge of the cover and destroy the cell. If I have also some cells which have been made at the edges of the combs, and which on account of their position cannot well be protected in the above way, I cut them out, fasten them separately in flat-pressed pipe-covers, which I close from the access of the bees with thin pieces of wood, and hang each cell near the top between two combs. All royal cells treated in this way generally hatch, and it is easy thus to arrange a regular breeding-cage, as four or five cells may be conveniently inserted in one passage."

Count Stosch said the honour of introducing the tobacco-pipe cover belonged to Dr. Donhoff.

Herr Weitzel said, "In Württemberg we have had experience and are convinced that artificial swarms are in all cases to be preferred to natural ones. In a country where natural swarms issue freely and in good time, it is of course superfluous to make them artificially." He then described his mode of making artificial swarms, which differs little from that already described in these columns by—A DEVONSHIRE BEE-KEEPER.

(To be continued.)

THE DISTANCE BEES FLY.

In Vols. VII. and VIII. of *THE COTTAGE GARDENER* you will find some observation on this head—it depends much upon the season. In the month of June, when the fields are covered with flowers, I do not think that the flight of bees exceeds from 800 to 1200 yards. Then, again, bees will take long flights when the lime trees are in full blossom; these blossoms seem immense favourites with them, for the bees will dash through heavy showers in an unusually fearless manner, and to the distance of a mile and a half, to wallow in the fragrance, and there is certainly a way with these insects of communicating intelligence to each other where bee pasture is to be found.

In your *JOURNAL OF HORTICULTURE* mention was made that hive bees were frequently seen on the Bass Rock, in the county of Haddington (East Lothian), between Dunbar and Haddington. I have visited the Bass Rock, which is three English miles from the main land, and I enjoyed a pleasant day's shooting at the Gannets, or Solan geese. No bees are kept on that beautiful and romantic little rocky island.

Bees will also fly a great distance late in the summer to find heath or white clover (*Trifolium repens*), but they are more

excited and busy when that sweet exudation called "honey-dew" is plentiful. This happens only about every third or fourth summer on an average of twenty years.

No doubt, as stated, much depends on the quantity of bee pasture, and the nearness to the favourite flowers, and the fineness of the weather; but where a great variety of bee flowers are to be found, from the end of May to the first week in July, the flight of bees is not above half the distance it is at other times.—H. W. NEWMAN.

BEE-FEEDING.

As a cannie Scotchman, I wish to say a few words to your correspondent "B. I. S." upon feeding. I had thought that we as a nation were the only party that had become addicted to the use of the bottle; but it appears that there are some apiarists across the Tweed becoming addicted to the use of it also. For this I am sorry; and as a bee-keeper of some years' experience I would suggest to "B. I. S." the propriety of his not adopting the bottle, as was done by our grandfathers, who threw it aside years ago. Let "B. I. S." adopt the system of feeding below, as approved of by your correspondent "UPWARDS AND ONWARDS," giving from 2 to 3 ozs. of syrup every night in tins shaped like razor-strops. Remove in the morning. Weigh once a-week, and see that the weight increases. Add a little extra covering as long as the nights are cold; and should he have a fertile queen, we will warrant plenty of bees to take advantage of the white clover when it comes in bloom.

By adopting the above plan "B. I. S." will also find that he will manage to feed six hives in the time that he would take to feed one with the bottle, and run no risk of chilling the brood. Let those who advocate the bottle try this plan of spring-feeding, and I am convinced that they will throw the bottle from them as being unworthy the advocacy it has received.—AN AYRSHIRE BEE-KEEPER.

OUR LETTER BOX.

PRESERVING EGGS (L. T. B.).—Dipping the eggs in melted fat and storing them in a dry cold place will preserve eggs as long as any mode of treatment. We have known them thus keep good from May until Christmas.

YARD FOR FOWLS (T. P. Ramsden).—You may keep a cock and six hens in your enclosed yard. As it is gravelled have a shed at one end with 6 or more inches in depth of sand on the surface for them to bask in; and a heap of limy rubbish for the hens to obtain material for their egg-shells. Supply them with as much green food as you can, such as grass-mowings and lettuce leaves. You will have an enclosed roosting and nest-house of course. Buff or Partridge Cochins, or Brahma Pouter pullets, will supply you best with eggs in winter.

EGGS NOT HATCHING (C. H. H. D. A.).—The eggs in question are clear eggs—i.e. they are not impregnated in any way. They have no germ of life in them, and consequently, if a hen were to sit on them for a year no change would take place. That which has never lived cannot die. The clear eggs if covered with butter, or put in lime when laid, will retain all the delicacy of a new-laid egg for months. That which spoils a good egg and renders it rotten is, that a hen should sit for three or four days till life has begun, then desert for some hours, causing death, then sitting again closely, the heat that would have brought the life to maturity merely putrefies the dead chicken. Boiled rice is better than raw, and if boiled in milk so much the better. It is very well as a change now and then, but as food it is poor stuff. For animals, as for human beings in our climate, it is only fit to be an auxiliary.

BEES (E. Fairbrother).—There is no particular management required for obtaining fertile queens. You will have seen what Mr. Newman says about the distant flight of bees. There are very few flowers from which they do not gather honey; but clovers, heaths, lime trees, beans, &c., &c., are wholesale pasturage for them. You have seen the drawings of Mr. Woodbury's hives, and you must consult a carpenter how best to alter your Taylor's hives.

DAY'S GAME PASTE (Hamburg).—You had better try it. It is said to prevent, as well as cure, both "gapes" and "roup." It certainly has testimonials in its favour from several gentlemen in various parts of England.

LONDON MARKETS.—APRIL 13.

POULTRY.

Good young poultry is getting scarce. The mild weather has caused much that would have remained tender to become hard. The winter stock is exhausted, the spring stock is not ready. Prices have advanced in some instances; and, but for the lack of trade and demand, poultry would be very dear.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 58.2° and 36.6° respectively. The greatest heat, 80°, occurred on the 25th, in 1840; and the lowest cold, 18°, on the 24th, in 1854. During the period 139 days were fine, and on 113 rain fell.

FERTILISATION OF ORCHIDS.

ILLINGLY, according to Mr. Darwin's request, I forwarded him a few seeds of the abortive *Cattleya crispa* flower referred to, and also a few seeds from a capsule that set spontaneously on *Lælia cinnabarina*, with the view of instituting a

comparison upon the reproductive tendency of a perfect and an imperfectly developed flower. The results of his analysis will, in all probability, be already in your hands.

I also sent by the same post a few of each of the above seeds to Mr. Gosse, who, after a careful microscopic examination, embodies the results of his views and experiments in a form which cannot fail to be generally interesting.

I may state, in addition to what I have already said, that the more I examine the positions of the organs of reproduction in Orchids, the more I am astonished at their power of producing seed-capsules without insect or other agency. At all events, it seems inconceivable why the pollinium of a perfectly enveloped flower should find its way to the stigmatic surface so as to produce even 2 per cent. of fertile seeds.

Mr. Darwin speaking of Dr. Cruger and Mr. Scott having observed the emission of pollen-tubes from the pollen-masses, brings to my recollection seeing the long, white, stringy, elastic tubes, which have, in several instances, been faintly discernible to the naked eye when the pollen-masses were irritated with the sharp point of a pencil. All those who have tried their hand at Sikkim *Rhododendron* crossing will have observed the same stringy masses, although on a much larger scale, by irritating any of the stamens. There is, therefore, not much anomaly in a perfect flower producing fruit with little or no artificial agency; although I am strongly of opinion, after a series of trials, that the germinating power of these pods that have had, so to speak, a spontaneous existence, is exceedingly weak.

It appears to me that bees are not such useful agents as moths, especially in the hot climate of our Orchid-houses, for probing the orifices of this wonderful and beautifully constituted genus; for although we have occasionally seen bees in the interior of the houses, we were never sensible of their making an attempt to seek nectar from the flowers, as they seemed quite uneasy at their close confinement. There is a species of insect, however, which is one of the worst pests to be found in an Orchid-house, that is admirably suited, with its long proboscis, for all the requisites of promoting fertilisation; and it may be, for anything I know, an agent in this

capacity. The insect I refer to is also exotic—a species of cockroach bearing the name of *Blatta orientalis*. They delight to feed upon the young roots and flower-shoots of all epiphytal Orchids, and require to be hunted down, else they would make such raids upon these valuable plants as to seriously deteriorate their value. Their time of working is at night; and although I have killed dozens of them upon the flowers, I have no mode in candlelight of discovering whether they ever detached the pollinia. In fact, we have all along only been too anxious to deal summarily with them.

Four out of the seven great divisions of Orchidaceæ comprise the greater number of plants cultivated for their ornamental appearance in our plant-houses; and out of these four the *Vandæ* form by far the most important division. It is a curious fact, if we except all those under the *Brassidæ* subdivision, not a single one of them, but the comparatively recent introduction *Sarcanthus Parishii*, has offered to set a seed-capsule. Of course, since I set about cross-breeding I have induced several to do so; but before I ever tried anything of the sort, none of the *Vandas*, *Ærides*, *Phalænopses*, *Saccolabiums*, *Maxillarias*, *Zygopetalums*, &c., made what I have, rightly or wrongly, called a spontaneous effort. The *Epidendræ*, on the contrary, have been conspicuous in seed-setting; and I only mention the fact for such scientific men as Mr. Darwin to ponder over and explain. *Cattleyas* often produce seed-pods, and occasionally *Lælias*, *Chysis*, *Epidendrums*, *Phaius*, *Schomburgkias*. We had a plant of *S. crispa* imported from Trinidad among some other things. It is the least ornamental of all the tribe, producing ten or twelve dingy-coloured wavy-edged flowers on the top of a stem about 5 feet long. These flowers only remained expanded about a day, or at most two days, and every one of them produced a seed-capsule, which goes a certain way to corroborate Dr. Cruger's observations.

Dendrobiums are the only representatives in the *Malaxæ* division that have formed pods spontaneously. In the *Cypripediæ* I have only in my experience had one attempt at seeding, and that was the rare and beautiful *superbiens* vel *Veitchii*; but it was a feeble attempt, ripening-off prematurely, which was never the case with me in any other species.—JAS. ANDERSON, *Meadow Bank, Uddingstone, N.B.*

MICROSCOPIC OBSERVATIONS ON SOME SEEDS OF ORCHIDS.

The following observations may possess some points of interest for the readers of THE JOURNAL OF HORTICULTURE. They were made on samples of seed sent to me by Mr. James Anderson—viz., that of a *Lælia cinnabarina*, which had set spontaneously from a perfect flower; and that from the pod which was produced by an abortive flower of *Cattleya crispa*, referred to in his communication, JOURNAL OF HORTICULTURE, p. 207. I have added some notes on seed of another *Cattleya*. The observations were all made with a power of 300 diameters.

LÆLIA CINNABARINA.—About 20 per cent. of the whole contain an embryo; the remainder consist of the empty

seed-coat. The former may be distinguished under the microscope by being much more plump, and by the central portion being of a pale olive hue, but quite pellucid. This colour marks the embryo, which is of an ovate form, filling the seed-coat as to its transverse diameter, but coming short of it in length. Its boundary lines in this direction are dimly visible, but may be well enough seen by focusing.

The dimensions of the fertile seeds, from an average of several carefully measured with a micrometer, are .014 inch in length by .0065 in width; those of the embryo, .01 in length by .006 in width. The unfertile empty seed-coats are generally much smaller, or about five-sixths the length of the fertile seeds, and not more than half their width, with no swelling. They are clear and colourless, except for the reticulation.

The seed-coat forms a loose sack-like envelope, widely open at both ends, considerably larger at one end than at the other, but not spindle-shaped. It is composed of what seems an open network, of which the meshes are five times as long as wide, apparently formed by flattened cells. Each sack is twisted, so as to make from one-quarter of a turn to a whole turn in its length. The netted texture is most advantageously seen in the empty ones. If I rightly understand the nature of this envelope, its meshes are only in appearance—there are no real apertures; what seem to be such being in truth composed of two laminae, the two surfaces of the flattened cells.

CATTLEYA CRISPA.—A far smaller proportion, not above 2 per cent. (3 in 160) of these seeds are fertile. Their general appearance is as in *Lælia*, but their form is longer, more slender, and more spindle-shaped, one end brought to a point, occasionally drawn out, the other end open. Their dimensions are .0187 in length by .0042 in width; those of the embryo .0084 in length by .0038 in width. The empty ones agree with the fertile in measurement. The network is much finer than in *Lælia*, the meshes closer and much longer, the length being nearly twenty times the width.

It may be interesting to compare with the above details the results of similar observations made on seed from a fine apple-like pod produced by a cross between *Cattleya labiata* and *C. intermedia*. The impregnation was in this case made by Mr. Dominy, who stands in the van of the infant art of raising Orchid seedlings, and to whose politeness I am indebted for the opportunity of making this examination.

About 80 per cent. of the seeds contain an embryo, which it requires a little practice to discern, since the well-filled seeds are scarcely less translucent than the empty seed-coats. The slight yellowish tint, however, betrays them; and then, by focusing, the outline of the embryo can be traced. By means of graduated pressure with the compressorium, while on the stage of the microscope, the pulpy contents of the embryo (which, according to Lindley, "*Vegetable Kingdom*," 2nd ed., p. 174, is "solid, fleshy, without albumen") are pressed out.

The form of these seeds agrees with that described above as belonging to those of *C. crispa*, except in being a little plumper in the centre, measuring about .0180 by .0060 inch.

An extremely curious and interesting phenomenon I observe in connection with these seeds. In many there is seen projecting from the obtuse end of the seed-coat, which is the open end, a short, wrinkled, opaque, blunt point, while in others this is wanting. If a drop of water be introduced into the compressorium, in which the seeds are, without touching them at first, and then, by turning the screw of the compressorium, the drop be gradually flattened so as to reach and embrace the seeds under the observer's eye, the phenomenon I allude to takes place. At the very instant of contact the little opaque point runs out into a long tail of brilliantly hyaline cells, arranged, except near the end, in a double linear series, and each furnished with a nucleus. If the observer's eye be upon one of the seeds in which no projection was visible, the effect is still more startling; for the tail of cells is then seen in a moment to start out from the open end of the seed-coat to a distance of about one-third of the entire length of the latter. By a little manoeuvring I was enabled to discern the origin of this singular filament. On pressing with the nib of a pen on the upper glass of the compressorium, the elasticity of the thin glass enabled me to augment or lighten the pressure by turns more delicately than could be effected by screwing the instrument. As I did this the embryo worked to and fro in the envelope; and, as it did so, projected and retracted the cellular filament, which was now seen to be a process of the embryo itself, springing from its extremity by an enlarged base. I suppose this filament to be

the radicle. Its extreme affinity for water, and the sudden vitality manifested by it in contact with that element, struck me as curious; and certainly to witness the phenomenon is highly interesting. I ought to add that it needs some degree of skill in the use of the microscope to exhibit it.

This seed from Mr. Dominy's cross I sowed on the 19th of March in a thumb-pot plunged in moss in a five-inch pot, the surface thinly covered with living moss, and a plate of dimmed glass set across the outer pot, which was then embedded in coal ashes over a hot-water tank in a temperature of about 80°. In ten days I examined a few of the seeds with the microscope, comparing them with those remaining in the sample unsown. The embryo had become opaque, of a bright green hue, and much plumper, its transverse diameter having nearly doubled. I was surprised that I could find no trace of the cellular filament, which I had supposed, perhaps erroneously, to be the radicle.

At the present time, about ten days later still, I find the embryo still more swollen, so as to be in some cases quite globular; no other change perceptible; no emission of filaments. The earliest process, then, appears to be the absorption of water by the embryo, and the diffusion of formless chlorophyll through the parenchyma.

The results, so far as the production of good seed extends, of these three experiments will stand thus:—

Cattleya, abortive.....	2 per cent.
Lælia, self-impregnated	20 per cent.
Cattleya, impregnated by hand,	80 per cent.

—P. H. GOSSE, *Torquay*.

THE ROYAL HORTICULTURAL SOCIETY'S AZALEA AND ROSE SHOW.

THIS took place on Wednesday last, which was one of those bright sunny days of which this year Spring has stolen so many from Summer. The flowers, too, were dazzling in their brightness—so much so that the eye, after looking at the masses of colour which the Azaleas presented, was glad to rest on the foliage plants by way of a relief. The general features of the Show, as well as some of its particular parts will, doubtless, be fully described by our able coadjutor "D," of Deal, who was busily employed note-book in hand.

Class 1, was for Azaleas of nine distinct kinds; and here Messrs. Veitch took first with, it is almost needless to say, beautifully-grown plants of Comte de Hainault, rose; Magnificent, white; Iveryana, white with carnation stripes, some of the flowers deep rose; Herzogin Adelheid Von Nassau, red, and crimson purple upper petal; Roi Leopold, pale salmon; Rubens, deep red; and Souvenir de l'Exposition, lilac and white.

In Class 2, which was for Amateurs, Mr. Todman, gardener to R. Hudson, Esq., Clapham Common, had the first prize for exceedingly well-grown plants of Concinna, Dr. Livingstone, deep rose; Iveryana, not well out; The Bride, pure white; Duchesse Adelaide de Nassau; Roi Leopold; Model, bright rose with crimson spots; and Rosea Alba, lilac edged with white. Mr. Higgs, gardener to Mrs. Barchard, Putney Heath, came in second, his plants being Beauty of Europe; Trotteriana, magenta; The Bride; Triumphans superba, rosy crimson; Louise Margottin, white; Marie and Iveryana, neither of them up to the mark; Wellington; and Magnifica.

The next Class, 3, was for six kinds, and open both to nurserymen and amateurs; and here again Messrs. Veitch carried off the first honours with Apollo; Queen Victoria, white striped with lilac purple, very fine; Triumphans; Splendens; Iveryana, a handsome specimen, and Petuniflora, deep rose.

Messrs. Ivery & Son, of Dorking, took second with Model, very fine; Crispiflora, rose; Baron de Vrière, salmon pink; Louise Margottin; Criterion, pale salmon, with white edges and crimson-spotted upper petals; and Gem, scarlet.

The third prize was awarded to Mr. Todman, for Dr. Livingstone, Optima, Prestans, Coronata, Novelty, and Eulalie, blush pink with crimson spots.

There were also several very fine exhibitions of Azaleas in the Miscellaneous Class. Those from Mr. Turner, of Slough, were magnificent specimens, forming dense masses of bloom. They were in 13-inch pots, on which account they could not be entered in the nurseryman's class, otherwise they must have carried all before them. They were shown in two collections, one of which occupied the end of the exhibition-room, forming an object which at once arrested the eye on entering, and were

arranged with Mr. Turner's invariable good taste as regards colour. They consisted of Rosy Circle, rosy pink; Vesta, white; Prince Jerome, deep salmon, with crimson spots; Ivoryana, a beautiful compact mass of bloom; Perfection, bright rose with crimson spots; Holfordi, rosy purple; Standard of Perfection, bright rose; Criterion, Gem, Roi Leopold, and Sinensis, rich deep yellow. His other collection consisted of some of the above sorts, with the addition of Duc de Nassau, rosy purple; Duchesse of Nassau; Rosalie; Trotteriana, very fine; Model; Admiration, white, striped with crimson; General Williams, salmon rose; and Chelsoni, orange scarlet, very fine. Messrs. Lane & Son, of Great Berkhamstead, had likewise a good collection; among which were *Conspicua purpurea*, with very large flowers of a lilac purple, with crimson spots; Juliana, salmon scarlet, with crimson spots; fine plants of Roi Leopold and *Præstantissima*, rosy salmon; and Chelsoni.

Altogether the Azaleas, exclusive of Mr. Turner's collection at the far end of the room, occupied 25 yards of stage; and they formed the grand feature of the Show.

In Roses, which will be specially commented on by another hand, Mr. Turner had the first prize for six in pots, which were Général Jacqueminot, Victor Verdier, Baronne Prevost, Coupe d'Hébé, Souvenir de la Malmaison, very fine; and Tea Souvenir d'un Ami. Mr. W. Paul was second with Cardinal Patrizzi, Madame Damaizin; Anna Alexieff and Madame Boll, both very fine; and Tea Souvenir d'un Ami, and Madame Willermoz. Messrs. Paul & Son, who came in third, had Charles Lawson, with large and very fine blooms; Paul Ricaut and President being also well worthy of note.

In the open Class, 6, for four Roses in pots, Mr. Turner had President; Queen of Denmark; Comtesse de Chabillant, very fine, as, indeed, it generally is; and Comte de Cavour, which is much in the way of Général Jacqueminot, but larger and deeper in colour. Messrs. Paul & Son had also a very good four, of which Général Jacqueminot and Victor Verdier were the finest.

Messrs. Lane & Son exhibited in the Miscellaneous Class twelve Roses in pots, among which were Louise Margottin, a beautiful delicate pale rose; Turenne, glowing colour but loose; and President Lincoln, deep velvety red, a good deal in the way of *Senateur Vaise*.

Cinerarias made a tolerable show, though there were not so many exhibitors as might have been expected in the case of a plant so useful for conservatory decoration, and of which their culture is so well understood. The specimens exhibited were, however, very creditable. The first prize in sixes was awarded to Mr. Lamb, gardener to Captain Cahill, of Southall, for Adam Bede, vivid purplish-rose and covered with a profusion of flowers; Queen Victoria, rosy crimson with white ring; Lady Seymour, white, deep blue edge; Mrs. Livingstone, rosy purple with white ring; Zingaree; and Loveliness. The second prize was awarded to Mr. P. Lamb, for Blue Bonnet, Lady Seymour, Admiration, Pilot, and Masterpiece; and third prizes to Mr. Holland, gardener to R. Peak, Esq., Isleworth; and Mr. Turner, of Slough.

Prizes were offered for greenhouse Acacias, but they did not induce competitors to come forward, although several good specimens were shown among the miscellaneous collections. With regard to Auriculas, Polyanthus, and Pansies, their return to the exhibition tables seemed to give satisfaction to a considerable portion of the visitors, judging from the interest with which the flowers were examined; and the feeling expressed in the remark which one old lady made in our hearing, "Well, I am glad to see these old flowers back again," was probably very generally shared. The principal exhibitors of these flowers were Messrs. Turner, Butcher, James, and Holland; but it is unnecessary to enter into detail here, as the merits of the different objects exhibited will be amply discussed in another column.

Of Cyclamens, those from Mr. Holland, of Isleworth, were remarkably fine both as regards the size and colour of the flowers; the varieties, however, were unnamed. To these the first prize was awarded; and an extra one was given to Mr. James, gardener to W. Watkins, Esq., for herbaceous Calceolarias, of which he showed several fine varieties.

Miscellaneous collections of stove and greenhouse plants came from Messrs. Veitch; J. & C. Lee, of Hammersmith; Bull, of Chelsea; F. & A. Smith; and Cutbush, of Barnet. In Messrs. Veitch's collection were two Acacias, *grandis* and *Drummondii*, the latter a fine specimen plant; *Rhododendron jasminiflorum*; also *Sesterianum* with large and beautiful white flowers;

several Azaleas; *Hedera tulipiferum*; *Eriostemons*; *Tetratheca ericæfolia*, a very handsome specimen covered with bloom; *Dendrobium densiflorum album*, with several fine spikes of bloom; *Ærides virens*; and *Anthurium Scherzerianum*, the brilliant scarlet spathe of which always calls to mind the ancient Roman standard. For this collection the first prize was awarded.

Messrs. Lee, who had a second prize, likewise exhibited an excellent collection, among which were a fine specimen *Epacris miniata*; Azalea Leesana, a handsome plant with large white flowers; Broughtoni; and several other fine Azaleas; *Eriostemons*; Heaths; *Saccolabium retusum*, with a beautiful raceme a foot long; and *Ærides roseum*, with two good spikes of its pretty rose-coloured flowers.

Mr. Bull likewise contributed an excellent collection, consisting almost exclusively of foliage plants, such as *Pandanus elegantissimus*, *Gleichenias*, &c., noticed on previous occasions.

The collection of Messrs. F. & A. Smith was composed of foliage plants as *Cyanophyllum* and *Allocasia*; some Azaleas, *Eriostemons*, *Erica affinis*, &c.; and that of Mr. Cutbush, of Barnet, was chiefly made up of Azaleas, with *Tetratheca ericæfolia*, but nothing equal to Messrs. Veitch's plant of the same kind, an *Aphelexis*, an *Eriostemon*, and one or two other plants.

Of other objects not coming within the scope of the schedule, S. Glendinning & Sons sent two trees of Fortune's rose-flowered Peach, a highly ornamental double variety, brought some years ago from the north of China. Mr. Bull exhibited the same groups of Geraniums and Petunias as shown at the Regent's Park on the previous Saturday; while Messrs. E. G. Henderson and Co. brought forward a group of perennial plants for flower-garden decoration, among which were Sunset and Mrs. Pollock Geraniums; white-foliaged plants, as *Centaurea candidissima*; a variegated Daisy called *Aucubæfolia*, the leaves of which were prettily variegated with yellow, as in the *Aucuba japonica*, and which would make a pretty edging plant; also *Govenia albicans*, with ornamental yellow flowers, and a variegated form of *Arabis alpina*. Hyacinths were shown in good condition by Messrs. Cutbush and Mr. Carr, of Highgate, the former having also six showy varieties of *Amaryllis*; Hardy Ferns by Messrs. Ivory and Son; and six fine pans of *Lycopods* by Mr. Higgs. A fine mass of the mauve bracts of *Bougainvillea glabra* came from Mr. Daniels, gardener to the Rev. C. Ruck Keene, Henley, and speciosa in small pots from Mr. Turner, of Slough, and Mr. Bull. Lastly, there were boxes of beautiful cut Roses of all the leading kinds from Mr. W. Paul, and Messrs. Paul & Son.

A BRILLIANT day, an excellent collection of flowers, and a goodly company, conspired to make this the most successful of the Spring Shows. But (why always these "buts" where the Royal Horticultural Society is concerned?) there were some drawbacks. In the first place the *tout ensemble* of the Show was completely spoiled by the flowers being separated in two of the corridors, or dining-galleries; for, as it had been wisely determined not to put the plants down both sides of the room, and thus to allow more ample sweep for the crinolines, this of necessity led to the separation of the flowers, and spoiled the appearance of the Exhibition. And, then, no precaution had been taken to wet the floors, either the previous night, or the morning of the Exhibition; and the consequence was that a cloud of dust, which would not have disgraced Rotten Row, was continually kept in circulation by the sweep of the ample dresses of the ladies. Over and over again I heard ladies say, looking into the room, "Dear me, what a dust!" and unconsciously leave. One cannot but ask why, as the Society must ultimately look to its exhibitions for a good portion of its funds, they should seem to have only a secondary place in the arrangements of the Council. The arrangements for these Spring Shows have been a series of makeshifts, and so every one has felt them to be.

And now to our special matter—the florists' flowers. Auriculas we were rejoiced to see are once more becoming popular. I have done my little best to make them so; and although, owing to the wretched arrangements of the South Eastern Railway, my own plants which arrived in London at noon on Tuesday were not delivered till nearly four and twenty hours afterwards—too late for the Show, I was myself unable to compete. I none the less rejoiced to see that several "new hands" too, although old growers, had come forward this time, and that there is every probability ere long of this beautiful spring flower resuming its old position around the metropolis.

Mr. Turner had, in our southern taste, some marvellously fine plants and flowers; and, although no competitor entered the lists with him, one may very safely say that it would have required something super-excellent to have beaten him. His twelve were, Duke of Cambridge, Pizarro, Mrs. Sturrock, Sir C. Napier, Am. Smith, Lovely Anne, Glory, Mary Ann, Catharina, Perfection, Apollo, and Smiling Beauty.

Amongst Amateurs, Mr. Butcher was first with Eliza, Badajoz, Duke of Wellington, Glory, Sir J. Moore, Pizarro, Favourite, and Privateer. Mr. James was second with Duke of Wellington, Eliza, Bright Phœbus, Lady Jane Grey, Duke of Cambridge, Mary Grey, Lady Blucher, and Robert Burns. Mr. Potts was third; and Mr. Holland exhibited some rather promising seedlings. Besides these Mr. Turner had a collection of twenty-eight varieties, amongst which were Ashton's Prince of Wales, Blackbird, Spalding's Metropolitan, Formosa (a most lovely shade of colour), Mary Gray, Eclipse, Lady J. Grey, Bellona (somewhat rough), Countess of Dunmore, &c.—altogether a very pretty show, and one which was evidently appreciated by many of the visitors.

Mr. Holland sent six Alpines, two of which I should not have considered to belong to that class.

A box of Pansies was sent by Mr. James; and also Fancy Pansies in pots. It is, however, somewhat too early in the season for them. We observed amongst Mr. James's flowers Lord Clyde, Telegram, Rev. H. H. Dombrain, Maid of Bath, Canary, &c.

Two collections of cut Roses came from the two firms of the brothers Paul, and were considered of equal merit. Amongst the newer varieties we noticed Beauty of Waltham; Madam C. Wood, very large; Eugène Lebrun, dark and well-filled; Jean Goujon, dark, not very full; Olivier Delhomme; John Hopper; Louise Margottin; Maurice Bernhardt, dark crimson and fine; Le Baron Rothschild, very brilliant and shell-like; Cornelia Kock, pale citron Noisette.

Besides many of the older flowers in good condition, the pot Roses were excellent—not the great gawky things one sees at the great shows supported by a forest of stakes, &c.; but neat, natural-looking plants, especially those of Mr. Turner, who has taken the place I was sure he would do, beating in Sixes his old-established competitors, the Messrs. Paul. His six were Souvenir de la Malmaison, Baronne Prevost, Coupe d'Hébé, Général Jacqueminot, Victor Verdier, and Souvenir d'un Ami. Mr. W. Paul was second with Cardinal Patrizzi, Madame Damazain, Anna Alexieff, Madame Boll, Souvenir d'un Ami, and Madame Willemoz. Messrs. Paul & Son were third with Paul Ricaut, President, Madame de Vetry, Jules Margottin, Charles Lawson, and Madame Damazain.

In Four Roses the same gentlemen were first with Jacqueminot, Souvenir d'un Ami, Belle de Bourg-la-Reine, and Victor Verdier. Mr. Turner was second with Souvenir de Comte Cavour (beautiful), Comtesse de Chabillant, President, and Queen of Denmark. The first-named was most beautiful, fine in shape, and brilliant in colour. Mr. Wm. Paul was third. Messrs. Lane had also a nice collection, not for competition, among which was President Lincoln, a promising flower; and Mr. Turner had a nice plant of that beautiful Tea-scented Rose L'Enfant Trouvé.

The Cinerarias I shall not attempt to speak of, farther than to say that I think there is a great mistake in the mode of exhibiting them. On the home-stage they are very pretty, but on an exhibition-table, tied-out and staked as they generally are, they are to my mind anything but ornamental.

There was a large collection of Hyacinth blooms sent by Messrs. Krelage, of Haarlem, which did not give one a very exalted idea of Hyacinth-growing on the Continent, containing nothing of novelty, except a curious-looking flower called L'Enfant de France.

There can be no doubt that these Spring Exhibitions greatly stimulate the growth of flowers; and another year will, I hope, lead to a more agreeable arrangement than the present season has witnessed.—D., Deal.

RED CAMOMILE TO DESTROY INSECTS.—The *Journal d'Horticulture de Belgique* states that a powder made from the flowers of Red Camomile (*Pyrethrum roseum*) emits "an odour so strong and penetrating that it kills all the insects and all the vermin of which until now no certain agent of destruction has been found."

NIEREMBERGIA GRACILIS.

LIKE your worthy correspondent Mr. Earley, I admire this pretty and interesting plant; but I fear I cannot vouch for its hardiness, although twice during the last fifteen years I have had beds of it that stood the winter pretty well. Strange to say, the most of the plants that I left in a bed the past winter are dead, though the situation is by no means a damp one, and the winter was unusually mild. I have been led to regard damp as more fatal to it than cold, as the parts of the plants now alive seem to be the extreme tips. I have, however, had a bed that stood through the winter, and flowered early and well, and it continued to do so the whole season. Such, however, was not the case with *Calceolaria*-beds that had stood and flowered in like manner; for they bloomed very abundantly early in the season, and, dry weather setting in soon afterwards, the after-bloom was anything but plentiful. This was in the summer of 1851, and the same thing has occurred once since then. Latterly, excepting for some special purpose, I have preferred destroying *Calceolaria* every season rather than run the risk of the uncertainty mentioned above.—J. ROBSON.

ORCHARD-HOUSES.

"Oh, wad some power the giftie gie us,
To see oursel's as others see us,
It wad frae monie a blunder free us,
And foolish notion."—BURNS.

IT is amusing to see with what pertinacity some people will ride their hobby. No sooner is an insinuation made against orchard-houses, or, more properly, fruit trees in pots, than up starts the champion, "R., of S.," who tells us in *THE JOURNAL OF HORTICULTURE* of last week, that "he has one quality which carries, and has carried, Englishmen through many ill-organised plans and many scrapes, and made them triumphant in so many quarters of the world—the most dogged perseverance." But perseverance would be more commendable in well-organised plans, which would save him from many scrapes. Can the gardener or amateur be sanguine of success when he is told in the *Journal* of the same date, by "DUCKWING, — Rector," that "the Plums, Vines, and Cherry I may dismiss at once, with an acknowledgment that I could get no blossom to set on the Plums and Cherry, and but few bunches, and those very poor, on the Vines. The Apricots have not done well. I have never had more than six or eight on a tree?" This communication was headed, "Merits of Orchard-houses." If such is the merit, I should think the demerit would be prodigious. Mr. Pearson also tells us in the *Journal* of the same date, that "Pears are not grown in my house because they were never good with me."

We are also told that Peaches and Nectarines are the only trees that have done well: therefore, "orchard-house" is a misnomer, it should be called the "Peach-house."

Gardeners should bear in mind the advice given in the preface to the "Theory of Horticulture." "The difference between failure and success, in practice, usually depends upon slight circumstances, very easily overlooked, and not to be anticipated beforehand, even by the most skilful; their importance is often unsuspected till an experiment has failed, and may not be discovered till after many unsuccessful attempts, during which more mischief may be done by extensive failures than the result is worth when attained. No man understood this better than the late Mr. Knight, who tells us in the following pages that it is the duty of gardeners to put in practice that which they have learned; and having to expend the capital of others, they ought to be cautious in trying expensive experiments, of which the results must necessarily be uncertain; and, I believe, a very able and experienced gardener, after having been the inventor of the most perfect machinery, might, in very many instances, have lost both his character and his place before he had made himself sufficiently acquainted with it, and, consequently, become able to regulate its powers."

It was a wonder, by-the-by, that Dr. Lindley did not think of this advice when he endeavoured to goad gardeners into an advocacy of the Polmaise system of heating.

Amateurs may try experiments, and blame themselves for failures; but if a gardener undertakes them he is responsible to his employer. The coiling-system of growing Vines in pots was strongly advocated by the late Mr. Mearns, at Welbeck; but of five hundred grown, fifty were fruited for exhibition, and when many gardeners lost their places, depending by limited means on a few for success, my esteemed friend Mr. R. Fish exploded

the whole in his correspondence on the subject. Whether he will give a *coup d'état* to the orchard-house question, time, after a little more investigation, will most probably tell.

The question resolves itself into the old epigram of the town in danger.

"A currier, wiser than all put together,
Says, 'Gentlemen all, you may think as you please,
But there is nothing like leather.'"

—WILLIAM KEANE.

ROSES.

MR. WILLIAM PAUL'S NURSERIES, WALTHAM CROSS.

THE great pleasure derived from a visit made a fortnight since to Mr. Wm. Paul's Nurseries induces me to remind amateurs and others, that a short railway trip by the Eastern Counties to Waltham Cross at the present season will afford them much gratification. Although the Roses were my special attraction, I cannot refrain from noticing the extensive and superb collection of well-grown Hyacinths then in perfection. Mr. Wm. Paul's success in the cultivation of this lovely spring flower is well known to the floricultural world; and the Hyacinths exhibited by him at the spring meetings at the Royal Horticultural Gardens, South Kensington, and the Royal Botanic Gardens, have been highly spoken of in the reports of these Exhibitions. The names and colours of the leading varieties have been fully described; and those who intend to grow Hyacinths next year would do well to procure Mr. Paul's catalogue of bulbs, 1862, and make notes of such flowers as have merited distinction.

But the Roses were my special attraction. It is impossible to describe the feelings which were excited on finding oneself in the last week of March standing amongst a vast group of well-grown and abundantly-flowering Roses. The peculiar brightness and vigour of the spring-green foliage with the brilliant and exquisitely scented flowers transferred me into Fairy Land. It is only of recent date that the luxury of early-flowering Roses has been indulged in. The treatment required is so simple and inexpensive; and the result attending the culture, which is generally so successful, furnishes a strong inducement for those who have space and opportunity to devote a crystal palace for the spring residence of the queen of flowers. A visit to the garden at Waltham Cross would verify these remarks; and any information desired on the subject will be always most willingly and courteously given. I shall send the names of some of the most striking varieties, whose merits I shall not attempt to describe; but most earnestly recommend all admirers of the Rose, and more particularly those of early-forced flowers, to lose no time in judging for themselves how easy a thing it is to enjoy the privilege and pleasure of having Roses in the highest state of perfection at this season of the year.

The following were among the varieties in bloom at the time our visit was made; but many others have since unfolded their lovely flowers, and among them will now be found one named after Mrs. W. Paul, the excellent form and surpassing beauty of which I will not venture to depict:—Charles Lefevre, Maurice Bernhardt, Eugène Bourcier, Monte Christo, Modèle de Perfection, Vicomte Vigier, Duc de Cazes, Louis XIV., Comtesse de Chabillant, Gloire de Santenay, Comte de Falloux, Louise Darzins, Prince Léon, François Louvat, Gloire de Dijon, Tea Madame de St. Joseph, and Tea Comtesse de Bartha, and many others. —X.

ROYAL HORTICULTURAL SOCIETY.

APRIL 15.

FLORAL COMMITTEE.—Another meeting of the above Committee was held in the Gardens, South Kensington, on Wednesday last, on the day of the third Spring Exhibition, which was especially appointed for Azaleas and Roses. Many very interesting specimens were brought before the Committee, and several certificates were awarded.

Mr. W. Paul, Waltham Cross, exhibited a very handsome *Magnolia Linné*, with large conspicuous purplish flowers. This plant was much admired, and received a first-class certificate. He had also a very promising bright carnation Perpetual Rose, Lord Herbert, which was requested might be seen again.

Mr. H. Page sent a white *Cineraria*, Snowflake, of dwarf habit a second-class certificate was awarded.

Messrs. Veitch sent *Alocasia zebrina*, a plant with large green

foliage on mottled stems: first-class certificate was awarded. An interesting though small Fern, *Cheilanthes Borsigiana*, the under side of the frond densely covered with gold: first-class certificate was awarded. *Browallia* species, with yellow flowers; *Azalea Marie Vervaene*, bright salmon, sometimes striped; *Azalea Madame Verschaffelt*, a showy decorative variety: second-class certificate was awarded. *Azalea Madame Dieudonné Spae*; also a half-hardy plant, *Valdivia Gayana*, with deep pink bell-shaped flowers; foliage not unlike a primrose.

Mr. Ivory, Dorking, sent *Azalea Beauty of Dorking*, a white flower striped with pink, of excellent form: a second-class certificate was awarded. *Azalea indica striata*, and *Athyrium Fieldii pumilum*, an interesting dwarf variety, but resembling closely *Athyrium Fieldii Iveryanum*.

Mr. Bull sent *Gloxinia Florette*, an erect-flowering variety, with white flowers, tinged or shaded with lavender. *Anthurium* sp., South America, a plant remarkable for its thick leathery leaves: a label of commendation was awarded. *Greenzvia aurea*, an old plant brought again into cultivation, forming a very handsome specimen, with bright yellow flowers, which were well displayed above the thick Sedum-like foliage: a first-class certificate was awarded. *Trichomanes membranaceum*, not in condition, requested to be shown again. *Uropedium Lindeni*, a very curious but well-known Orchid, with yellow and greenish flowers, remarkable for its long brown thread-like appendages. Three small pots of *Bougainvillea speciosa*, in full flower: a special certificate was awarded.

Mr. Turner, Slough, also sent a small plant of *Bougainvillea speciosa*, in full flower. This, as well as Mr. Bull's specimens, were struck from cuttings last autumn by Mr. Turner. The appearance of the small flowering plants of the *Bougainvillea* caused quite a sensation among the Committee. So much has been written about the successful cultivation of this plant, and the acknowledged difficulty in making it produce flowers, a special certificate was awarded Mr. Turner for his great achievement. *Azalea Louise Von Baden*, an exquisite white flower, of great substance and good form, the finest *Azalea* exhibited: a first-class certificate was awarded. Mr. Turner sent also two *Auriculas*—*Ensign*, a fine grey-edged variety, was awarded a second-class certificate; *Supreme*, an alpine, dark maroon border, with a bright circular yellow centre—a label of commendation was awarded. *Pansy Exquisite*, large flower, white ground, belted with violet, good eye—label of commendation. *Pansy Feu de joie*, a Fancy flower, upper and side petals white, ground shaded with mulberry, a large dark maroon centre—label of commendation.

Mr. Bragg sent a white bedding *Pansy Desirable*, flower not of sufficient substance. Messrs. Downie & Laird, a Tree *Carnation*, *Souvenir de Malmaison*; the flower a monster in size and monstrous in form. Mr. Parsons, *Cineraria Malvoisa*, a deep magenta.

Mr. Standish, Ascot, sent *Kerria japonica variegata*: a label of commendation was awarded. Also a pale pink, semidouble-flowering *Cherry* from Japan, which was awarded a label of commendation.

Messrs. Henderson, Pine Apple Place, sent *Camellia Giardino Santarelli*, a beautiful and promising flower, but, as exhibited at the last meeting, not in condition; *Tropæolum Ball of Fire*, a very bright scarlet-flowering variety, which was requested to be shown again to be compared with other *Tropæolums* in cultivation; *Retinospora leptoclada*—first-class certificate was awarded; and *Cupressus Lindleyana*.

Mr. Mills sent cut specimens of his Rose, *Pet*—a useful Rose for forcing, not very unlike *China Rose Archduc Charles*.

Mr. Hooper, Covent Garden, exhibited cut specimens of a very dark double *Polyanthus*, an improvement on the old variety, the bright yellow base of the petals rendering the flower more conspicuous.

Messrs. Smith, Dulwich, sent again *Azalea Surprise*, which on comparison very strongly resembled (as had been remarked on a previous occasion), *Azalea Madame Verschaffelt*.

FRUIT COMMITTEE.—Mr. Edmonds in the chair. Prizes were offered for the best three dishes of dessert Apples, for which there were four competitors. Mr. Cox, of Redleaf, sent remarkably fine specimens of *Golden Knob*, *Rosemary Russet*, and *Formosa Pippin*. In regard to appearance, both as to size and colour, they were much superior to the other exhibitions; but on cutting them they were all found to be passed and the flavour gone. Mr. Whiting, of the Deepdene, sent Herefordshire *Pearmain*, which was of good flavour but not fine; *Mickleham*

Pearmain, which bears a very close resemblance to Formosa Pippin was also pretty good; but Court-Pendu-Plat were as fine, both in regard of appearance and flavour, as could be desired. Mr. Hall, gardener to Captain Tyrrell, Fordhook, Ealing, sent Bess Pool, which was rather mellow, but of good flavour; Cluster Golden Pippin, hard, acid, and without any flavour; Golden Russet, inferior. Those exhibited by Mr. Earley, of Digswell, were Sam Young, Court of Wick, and Cackle Pippin, all inferior in size and flavour. The first prize was awarded to Mr. Whiting, and the second to Mr. Hall. Altogether the collections exhibited were not of a high order, not any of the specimens possessing the flavour desirable. The two best were Court-Pendu-Plat and Bess Pool, both two valuable Apples.

In Class B, four kitchen Apples, Mr. Whiting sent an unnamed variety, Royal Russet, and Devonshire Buckland. Mr. Earley sent excellent specimens of Hertfordshire Codlin, Norfolk Beefing, and Dumelow's Seedling; and Mr. Hall sent Norfolk Beefing, Dumelow's Seedling, and Yorkshire Greening. The first prize was awarded to Mr. Hall, and the second to Mr. Earley.

For the best dish of Strawberries there was only one exhibition, but a fine one. Mr. Barnwell, gardener to E. Mills, Esq., Bisterne Park, Hants. The sort was represented to be Keene's Seedling, but it appeared to us to be more like Sir Harry from the great size and very dark colour. The first prize was awarded to Mr. Barnwell.

Mr. Hill, of Keele Hall, sent five bunches of very beautiful Black Hamburg Grapes, large in size, and fine in colour, being perfectly jet. These were exhibited as specimens of what Mr. Hill has been cutting ever since the beginning of March. A very nice collection of salad plants was exhibited by Mr. Terry, gardener to Lionel Ames, Esq., The Hyde, St. Albans; it consisted of Cos Lettuce, Endive, Chervil, Tarragon, young Onions, Water Cress, Celery, Beet, Corn Salad, Long Radish, Turnip Radish, Mustard, Cress, and three young Cucumbers. The Strawberries exhibited by Mr. Barnwell formed part of a very neatly arranged box, containing some handsome Cucumbers and kitchen Apples. He also exhibited three remarkably fine heads of Broccoli, beautiful spring Cabbage, Spinach, and a fine dish of Mushrooms.

A seedling Apple of large size was received from W. B. Tyingham, Esq., Tyingham, Newport Pagnell. It is a large handsome Apple, roundish, and in size and shape like the Alfriston, and, like it, is covered with tracings of reticulated russet; but it is of a fine deep yellow colour, and has a blush of red on one side. The eye is small and closed, set in a narrow and rather deep basin. The stalk is very short, almost imbedded in the broad and russet cavity. The flesh is yellowish, tender, and fine-grained, and with a very excellent flavour and delicate aroma. This will be useful either as a kitchen or dessert Apple, but principally for the former, and it is said to keep till June and July. It was awarded a first-class certificate.

Mr. Ferguson, of Stowe, sent a seedling Apple the flavour of which was destroyed by having been in contact with some substance like moss.

Mr. Turner, of Slough, sent fruit of a seedling Strawberry called President, which had not much flavour. It evidently belongs to the race of Scarlets, and is a handsome-looking fruit; but the flavour will, doubtless, be improved later in the season.

T. B. Horsfall, Esq., M.P., Bellamoor Hall, near Rugeley, exhibited a very large bunch of *Musa Cavendishii*.

Mr. Ingram, gardener to His Grace the Duke of Rutland, Belvoir Castle, sent a dish of *Beurré de Rance* Pears, which were very fine in appearance, but they lacked flavour.

A PLEA FOR THE OLD FLUE—A GOOD BOILER ASKED FOR.

As the subject of heating horticultural structures is very properly attracting the attention of your readers, I beg to make some further remarks on the matter, and in the present instance I confess that it is as much with the view of eliciting information as of imparting it to others. Before proceeding further with the subject, I must thank those correspondents who have kindly come forward and given their opinion on the utility of the old and much-despised flue, as well as the more modern hot water.

The letter of "E.," at page 211, sets forth in a plain practical way the economy of the flue in places where coal is cheap, and

all intending builders of glass houses would do well to read his article. A heating apparatus capable of warming a house 40 feet long by 15 feet wide is put up for 50s. while the cost for fuel for the winter may be set down at 10s. or 12s., or less, and assuredly these figures are small enough for the most rigid economist.

In confirmation of the easy and useful working of the flue, the letter of Mr. Harris, at page 223, is equally valuable, and it states that Pines, Vines, Peaches, and plants can be forced or grown as well in houses heated with flues as with hot water, and as Mr. Harris has had experience in both, he may justly be allowed to have given an unbiased opinion. Contrasted with this is the letter of "J. E. L.," at page 258, who says, with one or two exceptions flues are a dead loss as compared with hot water, as flues are always out of repair, let the smoke out, cause nasty smells, and are accompanied by a dozen other annoyances. This is rather strong language on the part of "J. E. L.," whose after-remarks are also hostile to the old flue, and in praise of hot water. Now, I believe there are few people indeed who would not prefer a well-arranged system of hot-water-heating to the best smoke-flue in the world, were the cost of erecting the two somewhat alike; but I ask "J. E. L." and all others what sort of a hot-water-heating contrivance could be put up even at four times the cost, or £10, which will heat such a house as our correspondent "E." mentions, and be it remembered, that hot-water pipes are liable to mishaps as well as flues, and such accidents are more difficult to rectify. Any one can daub a little clay or mortar on a leaky flue, and it will go on for weeks as well as before, but it takes some time to replace a split boiler, and very often such misfortunes happen at the most unlucky time, as during the period of a sharp frost, or in the early spring forcing time, and the injury and inconvenience need no comment. I once had a boiler that broke down about Christmas, and the new one that replaced it gave way in less than a week after it was fixed, so that altogether about a month was lost, to the entire destruction of the permanent plants in the house. I do not remember of any such mishap befalling a flue in any part of my practice, although at one time I had upwards of twenty flue fires to manage. In saying this I by no means deny the likelihood of accidents with flues, but it is always easy to find a man capable of mending a flue, while the hot-water-pipe man is too often far away, and his operations are of a far more costly character than those in the other case.

Having given my views in a general form in a former article, I have but little to add now, excepting to repeat that I am by no means an opponent of hot water; but when the heat required is simply that sufficient to keep out a frost, or when, say, a temperature of 40° is wanted, the cheaper the heating contrivance that will accomplish that object, so long as it is effective, the better it is. Our correspondent "E." has shown that a house 40 feet by 15 can be heated with a flue for one-tenth of the sum that would be required for hot water. In his case, therefore, it would appear that he might have another small house for the amount he saves; at the same time it must be borne in mind he lives in the coal country, and some little allowance ought to be made for that. A hot-water apparatus is very defective indeed if a ton of coals will not command more heat by its means than by the flue; and when coals are 25s. instead of 2s. per ton, economy in them is of consequence. I wish in every instance to treat the matter impartially, and will, therefore, state that when the heat wanted is a continual temperature of not less than 55°, and fuel expensive, hot water may be more advisable. This, I believe, I fully explained in my former article, and the merits of flues being admitted by the correspondents alluded to, and as their utility ranks back at least a century prior to hot water, it is likely they may yet continue for a long time in use.

As "J. E. L." advocates hot water so strongly, perhaps he will give me some advice on the following points. Like Mr. Pearson, at page 257, I am far from certain that the best constructed boiler has been yet before the public, and, accordingly, I am far from being biased in favour of any particular one. The case is this:—My employers are about to erect a new lean-to house 68 feet long by 15 feet wide inside, and as it will be mostly devoted to forcing it will be heated with hot water, but not being connected with the other houses must be heated by a separate boiler. Now, I ask, Which is the best boiler? Every one understands the condition which this question conveys; but I confess being anything but sanguine as to the best-constructed one yet out being any way near perfection. I was once called on to look at a boiler in working order which was said to be

doing its work well, while the waste of heat was so great that a paper might be lighted at the top of the chimney. Economy of fuel must, therefore, be one of the requisites. I may add that we have in use three conical and two rather large corrugated saddle boilers, all of them tolerably good, but all, I think, capable of improvement. Another boiler of a different construction is less satisfactory, while Perkins's coil of pipes in use at the mansion is not adapted to gardening purposes.

If the house in question had been only intended for greenhouse plants, I would have been contented with a flue such as was described in a former article; but more heat being wanted, in what way is that to be effectually and economically obtained? Without being in the least prejudiced, I have rather a dislike to patents. They fetter rather than improve what originally existed, and in more cases than one that I could mention, they have proved losing affairs to those who took them out. This, however, is foreign to my subject, as I simply ask which is the best hot-water-heating contrivance at present in use. I shall be glad to have the opinion of practical men on the subject, and the question is one well worth discussing in the columns of THE JOURNAL OF HORTICULTURE. A few plain suggestions on the heating of a given space will suffice, and if we take as an example the house in question, which will contain a volume of 260 or 270 cubic yards of atmospheric air, might I ask for what could a hot-water apparatus be obtained that would efficiently heat that? and as a contrast between this and flues, it will be as many pounds as our correspondent "E." said his cost shillings. This, however, I leave for others to say. At the same time those who have a shallow pit heated well by somebody's boiler, must make some calculation of the small volume of air it has to work upon, and not too hastily pass any eulogium on its merits. To economise heat to the utmost is one of the best qualifications of a boiler, and whether this is already done in any of the boilers we now have or not is more than I can say. At all events let us determine which is the best.

J. ROBSON.

THE BARBADOES POTATO.

I HAVE not as yet been able to discover this valuable variety. Many people have fancied that they had it; but on examination their specimens, although somewhat resembling the old sort, have differed in the most important features.

This Potato is something like a Yam in shape, is often a foot in length; it has a skin as smooth as satin; it is very mealy with a rich flavour, and very prolific. It is also one of the earliest sorts. There has been no crop of it in this neighbourhood for seventeen years. Has this variety become extinct?—A CONSTANT READER.

[Messrs. Peter Lawson & Son, Nurserymen, Edinburgh, may have this Potato. They thus describe it in their "Agriculturist's Manual":—"Height of stem 2½ feet, rather upright; foliage loose and light green; flower light purple; tubers oblong, whitish, straight, much flattened, rather small, skin sometimes slightly tinged with red near the point. Increase ten-fold. Rather waxy, goodish flavour, pretty healthy, 672 grains troy of starch in 1 lb. of tubers."—Eds.]

GARDEN HELPS.

THE "helps" I have in my garden are the elder children. I get them up in good time in the morning, and then again after school-time. The exercise is healthful, and reward sweetens labour, as I give them 1d. per hundred for slugs and snails, and 1½d. per hundred for caterpillars.—D., *Newcastle*.

[The "yellow reptiles" are centipedes, and we believe not injurious to plants. We always consider that they consume decayed organic substances.—Eds.]

SPARROWS DESTRUCTIVE TO LETTUCE.

I AM fond of Lettuce, nothing to my mind being more refreshing than a nice White Paris Cos, fresh from the garden, with the usual et-ceteras. But the sparrows are also fond of their salad—a similarity of taste by which I have lately been a sufferer.

Last Friday I planted out a small crop, the plants used being rather young and tender; on Saturday they remained uninjured, but on Sunday the attack began, and I observed several sparrows

busily engaged with the green leaves. I determined that the bed should be protected by twine as soon as Monday came, but by that time every green leaf was gone. Not having any more plants I have had to sow again.

Having said this much against sparrows, it is but just to state in their favour that they were also busily employed in picking up insects on the adjoining new-dug ground. A market-gardener of great experience lately told me that, though troublesome at times, he considered the sparrow was the most useful bird we have.—TYRO.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

CŒLOGYNE LAGENARIA (Flask-shaped Cœlogyne).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Native of the Himalaya, bloomed at Messrs. Jackson's Nursery, Kingston-on-Thames. Flowers white, lip blotched with crimson. Unfortunately the leaves do not appear at the time of the flowers.—(*Botanical Magazine*, t. 5370.)

ENCEPHALARTUS HORRIDUS, var. **TRISPINOSA** (Three-toothed Encephalartus).—*Nat. ord.*, Cycadaceæ. *Linn.*, Dioecia Polyandria. Native of the Cape. The species has been called also *Zamia horrida*.—(*Ibid.*, t. 5371.)

CODONOPSIS CORDATA (Heart-leaved Codonopsis).—*Nat. ord.*, Campanulaceæ. *Linn.*, Pentandria Monogynia. Native of moist woods in mountains of Java, at elevations between 3500 and 8000 feet. A gracefully climbing plant with sickly-green flowers.—(*Ibid.*, t. 5372.)

LYCIOPLESIUM PUBIFLOEUM (Downy-flowered Lycioplesium).—*Nat. ord.*, Solanaceæ. *Linn.*, Pentandria Monogynia. Very handsome and coming from near Chiloe, probably hardy. Introduced by Messrs. Veitch & Sons through their collector Mr. Richard Pearce. Flowers purple, and remind one of the Foxglove.—(*Ibid.*, t. 5373.)

CYRTANTHUS LUTESCENS (Yellow-flowered Cyrtanthus).—*Nat. ord.*, Amaryllidaceæ. *Linn.*, Hexandria Monogynia. Cape bulb. Flowers graceful and very fragrant, produced in a warm greenhouse during February. Introduced by W. W. Saunders, Esq.—(*Ibid.*, t. 5374.)

CALANTHE VEITCHII HYBRIDA (Veitch's Calanthe).—A garden hybrid. Flowers pink. Obtained by Mr. Dominy, in Messrs. Veitch & Sons' Nursery at Exeter, by fertilising *Limatodes rosea* with the pollen of "that variety of the white *Calanthe vestita*, which has a purple spot at the base of the lip."—(*Ibid.*, t. 5375.)

FREE-FLOWERING MONOCHETUM.—Introduced by Messrs. Smith, Nurserymen, Dulwich. Flowers deep pink. A variety of *Monochetum sericeum*.—(*Floral Magazine*, pl. 141.)

DISK-SHAPED NEMOPHILA.—A variety of *Nemophila maculata*, raised by Messrs. Carter & Co., High Holborn. Corolla white, with the entire base of the disk deep purple.—(*Ibid.*, pl. 142.)

STRIPED JAPANESE CHRYSANTHEMUM.—Exhibited by Mr. Standish, Royal Nurseries, Bagshot and Ascot, who received it from Mr. Fortune. Florets some red and some white, with others striped longitudinally red and white.—(*Ibid.*, pl. 143.)

VARIETIES OF CAPE HEATHS.—Messrs. Rollisson, of Tooting. "*Erica profusa* (pink with white disk), raised between *Erica Macnabiana rosea* and *E. aristata major*, the former being the mother plant. *Erica affinis* (lemon-coloured), raised between *E. Cavendishiana*, also Messrs. Rollisson's seedling, and *E. depressa*, the last-named being the mother."—(*Ibid.*, pl. 144.)

CHRYSANTHEMUMS, raised by Mr. Salter. *Talbot*, "a deep rosy lilac with silvery tips," head close and full. *Princess Alexandra*, "outer florets deep blush-lilac on the outer surface, creamy within, and the central florets lemon-coloured," heads incurved and well filled-out.—(*Florist and Pomologist*, ii., p. 42.)

APRICOT CANINO GROSSO.—An Italian variety, from Canino, in the Papal States. Introduced by Mr. Rivers, Nurseries, Sawbridgeworth. Fruit larger than the Royal, melting, excellently flavoured, and peculiarly high-coloured; orange and red on the sunned side. Tree hardy and free-growing.—(*Ibid.*, p. 48.)

PROPAGATING MOST EASILY THE WEIGELA ROSEA.

HAVING noticed the question often asked, How to propagate the Weigela? I am induced to give the most ready way I have yet seen by which any quantity of it may be propagated with the utmost ease.

I admit that a most ready way, where at all applicable, is the old method of layering any shoots long enough for that mode; but such length of shoots we all know, where the stock in hand is small, is not at all times commandable.

I would, then, advise that cuttings of the Weigela be put out in precisely the same way, time, and otherwise, as are the

cuttings of Roses, dibbling them in as thickly and as quickly as we generally do the latter; giving them more room the following winter by transplanting, and making more bushy plants by judicious pruning. No plant we are acquainted with is more useful for spring forcing, or under proper treatment blooms more freely—certainly none with less trouble.—W. EARLEY, *Digswell*.

RHODODENDRON SEED, HYBRIDS, AND MANURING.

I BEG through you to return my best thanks to "D. C. M." for the paper of Rhododendron seed, from which I shall have much pleasure in raising plants. I presume that they are not seeds of the Sikkim varieties, or even of hybrids from them; but of the hybrid varieties raised between arboreum, ponticum, and catawbiense. Might I venture to ask of your correspondent another question, Whether he has attempted with success crosses between Rhododendrons and Azaleas? I am aware that some hybrids have been raised between the former and Azalea pontica, but has any attempt been made to breed between the Rhododendrons and Azaleas of the indica type, some of which have proved in several situations quite hardy?

I quite agree with "D. C. M." on the question of manure for

Rhododendrons. I habitually apply it to my plants, and with success. I remember one of the foremen at, I think, Messrs. Waterer & Godfrey's gardens telling me that manure was also very beneficial to many of the Pinuses in spite of the common prejudice on the subject. Of course, in this case, as in every other, very much depends upon the character of the soil.

As I am also a lover of spring flowers, I congratulate Mr. Browne on his acquisition of the double blue Periwinkle, which I have never seen. I have plants, or a plant at least, of the double purple variety you name; but I have never prized it in comparison with the blue or white. I fancy this variety is by no means rare; but should it be so, I shall be very glad to impart some of my stock to other amateurs.—J. N. M.

FLOWER-GARDEN PLAN.

1. Geranium Golden Chain, edged with blue Lobelia.
2. Balloon Trellis, covered with small white Rose.
3. Calceolaria Victory.
- 4, 7. Verbena Firefly.
- 5, 6. White.

8. Gazania splendens.
- 9, 10. Geranium Christine.
- 11, 15. Verbena Brilliant de Vaisse.
13. Calceolaria Aurea floribunda, edged with Baron Hugel Geranium.
- 12, 14. Lantana Sellovii.
- 16, 19. Verbena Purple King.

- 17, 18. Verbena Admiral Duncas.
20. Geranium Alma, edged with blue Lobelia.
- 21, 25. Heliotropium peruvianum.
23. Calceolaria Aurea floribunda, edged with crimson Minimum Geranium.
- 22, 24. Geranium Prince of Orange.

WE do not think that you, our correspondent "DIFFIDENCE," have any reason to feel yourself in difficulty. The main body of your geometrical garden consists of three parts—a centre and two wings, or they may be treated as three distinct parts, and yet forming a harmonious whole. This is the system of your proposed planting: Your centre is a circle with four beds round it, square on all the sides, except the inner one swept out by the curve of the circle. The circle you plant with Alma Geranium with a verge of Lobelia speciosa, and in this respect we like your arrangement much better than the Roses of "S. E. L." The four beds round are in cross pairs of Admiral Dundas Verbena and Purple King Verbena. Then each wing is centred with a diamond and surrounded with four figures; the outer lines square and at right angles, the inner line partaking of the character of the lines of the diamond. Both diamonds are filled with Calceolaria Aurea floribunda, and one is edged with Baron Hugel, and the other edged with crimson Minimum Geranium. Thus far the wings are balanced. Of the two Geraniums we think Minimum will be the most telling. The wing on the left-hand side has the four beds round the diamond crossed in pairs, two consisting of Lantana Sellovii and two of Brilliant de Vaisse Verbena; and if the Lantana is on peat and does well, the group will be very nice and come in well with the centre. On the right side the four beds are also crossed in pairs, two beds consisting of Prince of Orange Geranium and two of Heliotropium peruvianum.

This planting may be defended on the principle of having three centres and three different combinations of planting. The centre-and-balanced-wing principle has, however, been kept up so far as the planting of the diamonds is concerned, and therefore we would have liked better if the four beds round the right-side diamond had been planted in colours similar to those on the left-hand side, so as to balance thoroughly. Besides these main features, what constitutes a charm of this garden are five beds clustered on each side, owing to an open semicircular space opposite the circle-centre in the main garden. Now these accessory wings are so nearly balanced on each side, that we would be inclined to do it completely, and balance the main wings also, and use the same materials as you have. The largest beds on these subsidiary wings are Firefly Verbena, which we presume to be a bright scarlet. Very well; take the plants intended for these two beds, and use them in the right wing in the beds marked for Heliotropes, and bring the Heliotropes to the Firefly-beds. Then fill the little circles, Nos. 1 and 2, with Prince of Orange Geranium, and in place of them in the right wing have two crossed beds of pink Verbena or pink Ivy-leaved Geranium, &c., and then move your Golden Chain from No. 1 to the two little beds marked white. This would balance the whole; but we have no doubt the group would look well as you propose. Our opinion, however, is that the change would be more satisfactory.—R. F.

GEOMETRY APPLICABLE TO GARDENING.

NEARLY a century and a half since—namely, in 1718—one of the best practical gardeners of his period, Stephen Switzer, observed, that amongst the several businesses to which mathematics is applied, no where and in no case is it more useful than in laying-out of gardens and large estates. Extensively as the word Geometry is now applied, it was at first no more than the measuring-out, distributing, and fixing the boundaries or enclosures of the large demesnes, and the lesser or more immediate decorations of the noble villas and granges of the most ancient and most polite part of the world.

No change in our style of gardening has occurred since Switzer penned that passage rendering geometry less useful to the gardener. On the contrary, the bedding-out system requiring forms of geometrical figures and proportions; the discoveries relative to light rendering desirable accuracy of angle in the roof of a glazed plant-house; the easy determination of geometric curves in the designing and plotting of walks, roads, and the outlines of plantations; the designing of terraces, levelling, and other work, all falling occasionally upon the gardener as a part of his duty, and which he can only execute with certainty aided by a knowledge of geometry, we adopt this resolution of Switzer.

"I shall then apply what I have here to set down as necessary to be learned by all young surveyors and layers-out of ground, not mixing or confounding it with those many rules and problems that are contained in other books of mathematics, out of which it is not easy for a beginner, nor, indeed, for many gardeners of some standing, to collect what is useful and necessary to be known."

We shall partly republish what Switzer placed before his brethren, but we shall have the whole revised by a superior authority of our own time.

THE DEFINITION OF A LINE.

The line is a length without breadth, made by the motion of a point, and is of several kinds, as it receives difference of motion.

The right or straight line is that which is equally comprised within its extremities, as A B.

A ————— B

The curved line, is as plainly made from the round motion of a pair of compasses, as C D.

The crooked line is that which turns or wanders from its extremities by one or more turnings-aside, as E F.

The composite or mixed line, is partly crooked, and partly straight, as is the line G H.

The spiral line, called otherwise the volute, is described M N O.

(To be continued.)

VULCANISED INDIARUBBER TUBING.

I HAVE a splendid lot of young trees in my garden, as Plane, Sycamore, Mountain Ash, and such like, for the purpose of forming a shrubbery, and yesterday they were all I could have wished, being very forward and full of leaf; but to-day they are quite changed.

The foliage seems completely ruined and as if burnt by fire. The leaves on the upper surface have turned quite brown, and hang drooping from the bough.

The only way in which I can account for it is this: Last night I had out my indiarubber tubing for the first time this season, and gave all the trees a good watering excepting two, which I remember escaped, as it was nearly dusk when I did it; and now all but those two are in the condition above described.

I should be glad to know that I am mistaken in supposing that the injury was caused by the tubing, as I have gone to great expense in providing sufficient for my garden, and, therefore, I beg to ask you if you can enlighten me on the subject.

I remember noticing the same appearance upon the foliage last year, which I attributed to blight, and grieved I was to lose so many fine young trees. I am now disposed to think that it may have been the tubing and not the blight. The water is supplied from the cistern through a gutta-percha tube.—MOUNTAIN ASH.

ORCHARD-HOUSES—POT-CULTURE OF FRUITS.

EVERY one who happens to be in favour of the culture of fruit under glass will hail with pleasure such emanations as those from the pen of "T. R.," written as they are in a strain of good humour, and with a thorough appreciation of rural sights and sounds mingled with the skill of the horticulturist. The delightful picture he has drawn not only savours of the highest enjoyment, but is highly complimentary to the gardening profession. People of the most strictly sabbatarian views could hardly find fault with it, for there is no need to connect the Sunday contemplation of the contents of an orchard-house or a greenhouse with the necessary work of the week. Although such houses are to me the scene of weekday toil, still I can as agreeably pass the leisure moment in contemplation of the plants and flowers as though they were entirely fresh to me. In this respect I think the gardener possesses an advantage over men of other callings; and such notes as those of "T. R." are likely to confirm this view of the case.

I see no reason to doubt that Mr. Robson is both attached to his profession and a warm advocate of the garden in its utilitarian and decorative aspects, and I think he will not turn a deaf ear to the exhortation of "T. R." if he really see any cause for repentance. But it does not appear to me that Mr. Robson bears any animosity towards orchard-houses, or that he would discourage the practice of having fruit trees under glass. What he seems to imply is, that orchard-houses have as yet failed to realise all that has been promised concerning them; and that, although success is possible, yet failures have been very numerous. But then so they have been in other departments; and in the generality of cases where failures have been traced to their causes, they are found to result rather from the misapplication than the application of the principles on which the system is founded.

It is not a natural condition for any plant or tree to have its roots cramped in a pot, and yet most of the plants in cultivation are brought under that condition; and no one can doubt that however removed from nature that condition may be, there are few plants so treated but what seem to thrive, or, at least, are made to thrive under it; and there are plants which seem better adapted for cultivation in pots than in the ground, or in any bed of earth that could be made for them—as, for instance, many of the Cape Heaths, and other hardwooded hair-rooted plants. We see them grown to a state of the highest perfection it is possible to conceive in pots; but I never yet saw them grown well in a bed of earth—in fact, they appear to me to be so expressly adapted to pot-culture, that no other condition seems to be applicable to them. At any rate, I am not likely to try them by turning them out of pots.

To talk of any particular class of subjects being totally unfitted for pot-culture, is, I believe, contrary to all acknowledged rules, for what plant or tree is there worth cultivating at all that will not submit to have its roots brought within the compass of a pot or tub? Nor are we influenced in any way on this point by the natural habitat of the plant itself, whether it be from the mountain side where it is exposed to bleak winds, or from the low marsh, from the burning plain, or the rocky dell, from the running stream of water, or suspended in the air; we have plants under cultivation in pots which represent all these conditions of humidity and temperature, and all seem to adapt themselves kindly to the circumstance, provided their natural conditions of air, light, heat, moisture, and soil, are afforded. Still, as before mentioned, there are some plants which seem better adapted to pot-culture than others; and while I for one would

rather grow fine-rooted plants, as Cape Heaths, in pots, I should prefer a bed of earth for the Cucumber and the Melon; and though I have known them grown well in pots, yet a bed of earth either in a frame or Cucumber-house, seems to be the best and most natural method, and I certainly prefer it.

Then, with regard to the Pine Apple. Many grow this fruit in beds of soil, dispensing with pots altogether, and say that time and trouble are saved; but whether this is really preferable to pot-culture, there is, I believe, reason to doubt, for those who dispense with pots do not always find the course of Pine-culture run smooth. Then, again, with regard to the Vine: it is natural to suppose that when Vines have a good border to root into, they are more likely to produce a yearly crop of fruit with less labour than if grown in pots. Nevertheless, the pot-cultivation of the Vine has its advantages; and as good Grapes can be grown in pots, and large numbers of Vines are raised every year for the purpose of fruiting in pots, there is no likelihood of the practice being discontinued.

Now, I consider it is just the same with Apples, Pears, Plums, Cherries, &c., as it is with Vines. We naturally look for abundant crops of these fruits from trees cultivated in the usual way, and the principal supply for the markets must certainly be from orchards; but if our orchards never failed to yield their yearly supply of fruit, there would be one advantage in having orchard-houses, and that is for an early supply. But then fruit-culture in the open air is subject to many vicissitudes. The preceding season may have been wet and cold, consequently the wood has failed to ripen; or the blossom-buds are eaten by birds; or the flowers are beaten off by storms of wind, hail, or rain; or if the fruit set, it is eaten when in a green state by grubs, and when ripe by birds. Sometimes the yield happens to be abundant in spite of all these obstacles; but very often the trees are obliged to succumb, and the owner looks in vain for his return. Now, it is just in order to evade all these impediments that orchard-houses are built; and if a suitable border is made, and the trees planted in it, all well and good. They may be kept dry in order to ripen the wood at the proper season, and the buds, blossoms, and fruit, are protected from birds, blighting winds, &c. The chances of obtaining regular and certain crops are therefore increased; but then, many are not satisfied with this, and like to have their trees in a more portable style. They are, therefore, put in pots. In this condition they can be moved about at pleasure. The roots need not be cramped, if the pots only be proportioned to the size of the trees; nor need they be starved for want of nourishment, since it may be supplied to them in the form of liquid manure. If just enough of this is given as the tree requires it, the roots will show no disposition to ramble, even though they may have the chance, in search of nourishment.

That orchard-houses are often failures as regards the supply or the non-supply of fruit is undeniable; but then is it because orchard-houses are altogether on a wrong principle? or is it not rather that in individual cases the trees are not managed on a right one? Among several different collections of potted trees that I have seen, I have failed to distinguish any indication of skilful manipulation. The relative proportions of the pots and the trees seemed to have been totally disregarded. The latter appeared to have been roughly dug out of the ground, bundled into the pot in the most careless manner, and the pot filled to the very brim with the very coarsest soil, then the collar would stand 6 inches above the top of that, and anywhere but in the centre—together when finished the tree having anything but the appearance of a well-balanced pyramid. Why trees should be treated in this way, and then expected to bear fruit and do well, I cannot imagine. The same gardener who treats his orchard-house trees somewhat in this way, behaves very differently towards his flowering plants. These are carefully and neatly potted, the pots being proportioned to the plants as they advance. Why cannot the same treatment be applicable to pot-grown orchard-house trees? Surely the old maxim, that what is worth doing at all is worth doing well, is applicable to these; and I fancy that those who are successful with orchard-house trees, are really as careful with them when young and as they grow up as one would wish to be with the choicest greenhouse plant. And wherein consists the greater claim of the latter to such unremitting attention? A well-grown Azalea or Chorozeema is a beautiful object when in bloom. So is a well-grown Peach or Apple tree even in a pot; but in the case of the latter there is a great advantage, for after the blossom falls the tree is still an object of interest on account of the fruit. When that is ripe

the tree is again an object of beauty not only to the eye, but offers its luscious burthen for the gratification of other senses, particularly that of taste.

No one who has successfully cultivated fruit trees in pots, or ever seen good crops of fruit so cultivated, would ever offer a word in opposition to orchard-houses, unless circumstances should render them altogether superfluous. If Mr. Robson is not particularly favourable towards them, it does not follow of necessity that he should be strenuously opposed to them. In a district so favourable to the cultivation of fruit as Kent, the advantages derivable from orchard-houses may be trifling, that of earliness being the chief, while the time and attention required are increased very much. But there are many districts where the fruit crop is far more uncertain than it is in Kent—where, in fact, some of the more tender kinds seldom produce crops of good size and flavour. It is in such places that the advantages of the orchard-house are seen by contrast, where it is a mere matter of certainty of the in-door in contrast with the uncertainty of the out-door crop, and then the management of orchard-houses and their inmates becomes of double interest. Many are content to cultivate fruit under glass who would not care to cultivate flowers alone, or to build houses for them; and orchard-houses have certainly been a means of stimulating the love of horticulture, and giving it a wider scope than it would have otherwise received.

The question may be asked, What is the successful management of orchard-houses? The amateur who merely amuses himself with a small house and a few trees, is delighted if two-thirds of them bear fruit in one season, and is content with one-twentieth part of the fruit that might be produced on a tree covering the same space as his orchard-house. This is not the case with the practical gardener; he is content with nothing short of the same amount of fruit, or even more than would be produced on the same surface, supposing it were covered with healthy bearing standards, the earliness and greater certitude of obtaining regular crops being considered equivalent return for the necessary outlay.

If regular and early crops are to be obtained by means of orchard-houses, then certainly these advantages are indisputable; but how is that regularity of bearing to be arrived at? and this, probably, is just what amateurs would like to know. Well, it just amounts to this: Induce your trees to make fruit-bearing wood, and when it is made, harden it and ripen it well. The former is to be done by encouraging a kindly root-action during the growing season; a proper heat and humidity both at top and bottom will do this, and everybody knows what fruit-bearing wood is when they see it. To ripen the wood retard root-action, but not suddenly, by keeping the roots cool and dry, and well expose the wood as much as possible to the sun. On these points success mainly depends. The next in importance is, I consider, to let the fresh air have free access to them, and let them break gradually, so that the new growth is strong and healthy. Many trees drop their buds and first leaves from being started too hastily by being kept close. There are other essential points, as giving them suitable soil, repotting when the wood is ripened, thinning the fruit and the young shoots, &c.; but if amateurs would give proper attention to making and ripening the wood, their trees would be productive, and there would be few complaints of failure.

Experienced growers are in the habit of discussing technicalities, taking the main points for granted. The inexperienced amateur catches at these minor matters, and follows them to the letter. He measures to an inch the size of the pots, to a day the time of potting, also to an ounce the proportions of loam and dung of which the soil is composed, or is very particular about washing off the blossoms when the fruit is set, if it should set, and other small matters which come naturally enough in their season; but that plodding, untiring watchfulness on which success depends is not to be thought of, so that the trees receive only a fair share of attention when they are most attractive. To the ordinary observer success in any particular branch of horticulture speaks of cleverness and skilful handling; but to the gardener it also indicates hard, plodding industry, and a watchfulness that in any branch of industry would not fail to bring success.

This brings me to a point in "T. R.'s" letter which appears to reflect on the customary practice of exhibiting specimens of horticultural skill, which is certainly done by the majority of exhibitors with the view of taking prizes. Doubtless the reflections of a man of genius differ widely from those of the mere prize-

taker; but does it follow that every exhibitor is a mere prizetaker? What I have experienced in the way of exhibiting has been only as a subordinate—that is, I have merely assisted in growing the plants, taking them to the shows, &c.; and it is nearly a dozen years ago since I had anything to do with shows, so that I cannot conscientiously have much to say concerning them. I have formed opinions averse to showing, because I have known those who have made it a profitable trade and who regarded their plants merely as objects for obtaining prize-money, and who would deny that any plants were worth growing for which prizes were not offered. But then it is not fair to assume that these are the views of all but a very small proportion of exhibitors. I believe that in the majority of cases it is from a laudable desire to show what can be done by perseverance and knowledge; and that while some real and tangible momentum is given as acknowledgment of various degrees of excellence, by far the most gratifying result is the fame thus obtained.

Apart from the motives that actuate exhibitors, it is unquestionable that horticultural shows have done more than anything else to bring gardening to its present high position. They have given rise to competition, and stimulated men to endeavour to excel each other in producing specimens of superior skill in that useful and decorative art which is ever progressive. —F. CHITTY.

THE VAN MONS THEORY OF FRUIT-RAISING.

EXPERIMENTS IN ILLINOIS.

THE following facts have been elicited from correspondence with H. P. Brayshaw, of DuQuoin, Illinois. The experiments were instituted by his father many years ago to test the truth of the so-called Van Mons theory of the improvement of fruits by using only the first seeds.

Mr. Brayshaw quotes from memory chiefly, having kept no record. Thirty-five years ago, in 1827, his father procured twenty-five seedling trees from a nursery, which may be supposed to have been an average lot grown from promiscuous seed. These were planted, and when they came into bearing, six of them furnished fruit that might be called "good," and of these "four were considered fine." One of the six is still in cultivation, and known as the Illinois Greening. Of the remainder of the trees, some of the fruits were fair, and the rest were worthless, and have disappeared.

Second Generation.—The first fruits of these trees were selected, and the seeds were sown. Of the resulting crop, some furnished fruit that was "good," but they do not appear to have merited much attention.

Third Generation.—From first seeds of the above one hundred trees were produced, some of which were good fruit, and some "even fine," while some were very poor, "four or five only merited attention." So that we see there was a retrogression from the random seedlings, furnishing 25 per cent. of good fruit, to 4 or 5 per cent. in the third generation that were worthy of note.

Fourth Generation.—A crop of first seed was again sown, producing a fourth generation; of these many were "good culinary fruits," none, or "very few being of the poorest class of seedlings;" none of them, however, were fine enough "for the dessert."

Fifth Generation.—This crop of seedlings was destroyed by the cut-worms, so that only one tree now remains, but it has not yet fruited. But Mr. Brayshaw appears to feel hopeful of the results, and promises to continue the experiment.

Second crops have also been sown from some of these trees, but a smaller proportion of the seedlings thus produced were good fruits than when the first seeds were used—this Mr. Brayshaw considers confirmatory evidence of the theory, though he appears to feel confidence in the varieties already in use, most of which have had almost an accidental origin.

He thinks the result would have been more successful had the blossoms been protected from impregnation by other trees, and recommends that those to be experimented with should be planted at a distance from orchards so as to avoid this cross-breeding, and to allow of what is called breeding in-and-in. If this were done he feels confident that "the seedlings would more nearly resemble the parent, and to a certain extent would manifest the tendency to improvement; and that from the earliest-ripened fruits, some earlier varieties would be produced; from those latest ripening, later varieties; from those that were

inferior and insipid poor sorts would spring; and that from the very best and most perfect fruits we might expect one in one thousand, or one-tenth of 1 per cent. to be better than the parent." This diminishes our chances for improvement to a beautifully fine point upon which to hang our hopes of the result of many generations of seedlings occupying more than a lifetime of experiments.

Mr. Brayshaw, citing some of the generally adopted axioms of breeders of animals, assumes that crosses as of distinct races will not be so likely to produce good results as a system of breeding in-and-in persistently carried out. This plan he recommends, and alludes to the Quince and Mulberry as suitable species to operate upon, because in them there are finer varieties, and therefore less liability to cross-breeding, and a better opportunity for breeding in-and-in. He also reminds us of the happy results which follow the careful selection of the best specimens in garden flowers and vegetables, combined with the rejection of all inferior plants, when we desire to improve the character of our garden products; and he adopts the views of certain physiologists, which, however, are questioned by other authorities to the effect that violent or decided crosses are always followed by depreciation and deterioration in the offspring.

The whole communication referring to these experiments, which are almost the only ones, so far as I know, which have been conducted in this country to any extent to verify or controvert the Van Mons theory, is very interesting; but it is easy to perceive that the writer, though apparently very fair and entirely honest, has been fully imbued with the truth and correctness of the proposition of Van Mons, that the first ripened seed of a natural plant was more likely to produce an improved variety, and that this tendency to improvement would ever increase and be most prominent in the first ripened seeds of successive generations grown from it.

The theory of Van Mons I shall not attempt in this place to controvert, but will simply say that nothing which has yet come under my observation has had a tendency to make me convert to the avowed views of that great Belgian pomologist; while, on the contrary, the rumours of his opponents, that he was really attempting to produce crosses from some of the best fruits, as our gardeners have most successfully done in numerous instances in the beautiful flowers and delicious vegetables of modern horticulture, have always impressed me with a colour of probability, and if he were not actually and intentionally impregnating the blossoms with pollen of the better varieties, natural causes, such as the moving currents of air, and the ever active insects, whose special function in many instances appears to be the conveyance of pollen, would necessarily cause an admixture, which in a promiscuous collection, like the "school of Van Mons," would at least have an equal chance of producing an improvement in some of the resulting seeds.

The whole subject of variation in species, the existence of varieties, and also of sports which may perhaps be considered as still more temporary variations from the originals than those which come through the seeds, is one of deep interest well worthy of our study, but concerning which we must confess ourselves as yet quite ignorant; and our best botanists do not agree even as to the specific distinctions that have been set-up as characters of some of our familiar plants, the most eminent authors differing with regard to the species of some of our most familiar genera of trees and plants.—*From a paper by Dr. J. A. Warder, read before the St. Louis Horticultural Society.*—(Prairie Farmer.)

DISTRESSED LANCASHIRE WORKINGMEN BOTANISTS.

ALLOW me to thank your numerous readers for their kindness in sending me the means to help some of England's worthiest sons and daughters, in spite of the bad name we have through the late unfortunate riots.

I am happy to say that the older operatives were thoroughly disgusted with the hubbub that was kicked up by some foolish lads and lasses; yet owing to those riots I never expected to receive another penny for my little flock.

I am happy to say, however, that the kind-hearted Lady Nevill has sent me her usual donation of £1, and H. B., 2s. 6d. I also omitted 2s. I had received for six cuttings of "Little Dot." —JOHN HAGUE, 36, Mount Street, Ashton-under-Lyne.

WORK FOR THE WEEK.

KITCHEN GARDEN.

WHERE Broccoli and Winter Greens are coming off, the ground should be deeply trenched, the stems being laid at the bottom and quicklime strewed over them; also, if the ground is intended to be again planted with any of the Brassica tribe, it should have some manure incorporated with it, but it is best at all times to change the crops as far as practicable. *Capsicums*, repot the plants of the larger varieties intended for turning out next month. Harden them off when they have taken fresh root-hold. The small sort generally called *Chilias*, should also be potted in rich soil as they require, and to be kept in a stove or warm house. *Carrots*, the frames may be removed from the early-sowing if required for other purposes; thin and water them when necessary. *Cauliflowers*, keep the ground well moved about them, and also about the Cabbages, and lose no opportunity of destroying slugs. *Celery*, some of the earliest-sowing that has been pricked into boxes may now be planted in a frame. No artificial heat is required; but the lights should remain on in cold wet weather. Prick out the successional sowings. *Dwarf Kidney Beans*, sow on a warm sheltered border; also, a few Scarlet Runners and Haricot Beans, but these succeed so well transplanted that it is best to provide for contingencies by sowing them in pots or boxes, and germinating them under glass. When well up remove them to the open air, and cover at night, and transplant them about the beginning of the second week in May. They will come into bearing more than a week before those sown in the open ground, and will continue to bear quite as long; add to this the certainty of a crop, and the facility of protecting them in the earlier stages when they are so apt to be nipped by the spring frosts. *Lettuce*, forward the spring-sown plants where there is a scarcity of autumn-sown ones. Water them in dry weather and keep the soil loose about them. Sow seed of the Black-seeded, Bath, and Paris Cos. *Onions*, thin out the autumn-sowing. The plants drawn out may be replanted into beds. After they are thinned-out to regular distances loosen the soil between them. *Peas*, earth-up and stick the advancing crops. Before earthing use soot for the purposes we have before recommended. *Radishes*, make a sowing of Turnip-rooted kinds; water those in frames when dry, to preserve their tender and mild qualities. *Red Beet*, sow a full crop towards the end of the week. *New Zealand Spinach* may be sown in heat for transplanting in May; and Vegetable Marrows and the Ice Plant where the latter is required for garnishing.

FLOWER GARDEN.

Attend to the pruning of evergreen shrubs. Remove all dead branches. Hoe, rake, and stir the surface of flower-borders, and remove all decayed leaves and stalks of plants which have done flowering. Thin out early-sown annuals in open borders to from four to six plants in each patch. Give standard and dwarf Roses a good soaking with manure water, which will excite vigorous growth and insure an abundant bloom. Autumnal-flowering Roses, especially, delight in such treatment. Put out alpine plants on rockwork. Shade *Auriculas* coming into bloom. Pot *Carnations* and *Picotees* for blooming, and protect from heavy rains. Plant out *Pinks* if not done. Make new beds of *Pansies*, and propagate from side suckers under hand-glasses, shading them until rooted. Plant out beds of *Stocks*, and sow German and other sorts for autumn-blooming. Continue to propagate *Dahlias*, and shift those previously struck, giving air freely to prevent drawing. Divide and pot *Lobelias*, and start them in heat.

FRUIT GARDEN.

All trees on walls should now be looked over, and have their wood thinned while in the bud, taking-off with the finger and thumb all foreright buds, and others that are not properly situated for laying-in. Thin also the young canes of *Raspberries* to the number necessary for next year's crop. By this means the canes will be stronger and ripen better. Also remove all the foreright shoots from *Apricot* trees, and a portion of the side shoots; but endeavour to distinguish those which are likely to form short fruit-bearing spurs, which must always be left.

GREENHOUSE AND CONSERVATORY.

Repot growing plants as may be necessary. Regularly shift tender annuals, stake them, and give water in large quantities as they advance, using liquid manure to the strong-growing kinds. Forward *Calceolarias* and *Cinerarias*, and keep them clear of insects. Water *Camellias* freely with weak manure water, but do not let the water hang about their roots; keep the shifted

ones close and warm. Heaths and New Holland plants to have abundance of air, and to be watered very carefully. Shift *Pelargoniums* wanted to flower in autumn, and propagate desirable sorts. Keep all climbers, whether in pots or otherwise, regularly trained. Keep the conservatory as cool by day as is consistent with the health of the inmates. This will keep the plants longer in bloom, and be more enjoyable for parties inspecting them. Shading must be resorted to in this bright weather.

STOVE.

Give a final shift to the early-flowering *Achimenes*, *Clerodendrons*, *Gloriosas*, *Geaneras*, *Begonias*, &c., and keep them close for awhile, and water free-growing plants generally with weak manure water. The last succession of *Achimenes*, to flower late in the season, should now be placed in heat. Employ pans or broad shallow pots for their general cultivation, and as they require an abundant supply of moisture when they are in flower, let the drainage be as efficient as possible in order that they may be freely watered without stagnating and souring the soil. *Oreohids* are now progressing fast, and will require attention in shading daily and gradually increasing the humidity of the house, so as to keep pace with the increase of solar light and heat. If the roof is covered with the creepers a little management in training them, to effect a judicious shading of the plants beneath, will save much trouble with external shading, which will only be needed on very bright days, and add much to the appearance of the house.

PITS AND FRAMES.

Clear out some of the hardier bedding-out plants which have been under glass during winter, place them in some sheltered situation, and where they can be readily protected in case of frost or cold cutting winds. This will make room for some of the young stuff potted-off some weeks ago. W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

STAKING Peas, manure-watering Broccoli, Cabbage, &c., turning and banking-up linings of Cucumber-beds, liming Radishes, Turnips, &c., and taking lots of the Greens tribe to the rubbish-heap, as we do not want to make a disagreeable smoke with charring just now, and when covered over with rough earth the stalks and tops will be good compost before the middle of the winter. Threw dung, leaves, &c., together for a small fermenting-heap, and after this begin to be more independent of dung for artificial heat, as the mowings from the lawn come in, as these can be made to give a good heat for temporary purposes. General work much the same as the last and previous weeks.

FRUIT GARDEN.

Turned out all the Strawberry plants done fruiting, and planted them for autumn and next year. Thinned Grapes. Average temperature 60° at night, and 75° to 85° during the day when the sun shines. Second viney coming strong at a lower temperature; will regulate it as soon as possible, as all the rods are not yet in their places, as we were obliged to bend some to cause them to break regularly. Late viney has all the wood close to the front of the house, and is kept as airy and cool as possible; but we have not been able to keep it from breaking, so that we shall have to tie up to prevent rubbing off young shoots and fruit, though to all appearance there will be plenty of the latter to spare. We should like to keep them quiet as much as possible for some time yet, so that the flowering would come on in the hot weather, as after that time there should be less of anything like a check; and if this simple principle is kept in view, amateurs may have pretty early Grapes in autumn with the smallest expenditure from the coalheap. The shutting-in the sun's rays is the best of all heat; and the economist's motto, with a combination of safety, should be, "Give air early in the morning, and take it away early in the afternoon." If coal is no object leave air on constantly, but a rather close atmosphere at night is less dangerous if air is given early in the morning; and small openings soon change the atmosphere of a house. Nipped the shoots of Figs when necessary, making sure of some stumpy pieces to stand over the autumn, and watered them at the roots, the crops being extra heavy. Thinned out any shoots to spare in the Peach-house, and must thin the Strawberry-pots on shelves ere long, as they tend to darken the house too much. Laid out Melon-runners on the plan described last season. Sowed a few more for late crops, having plenty in good-sized pots to turn out as soon as room can be obtained, and had

another clearing at the trees in the orchard-house, having had an extra supply of the brown or black beetle, the larvæ of the *Aphis Persicæ*, last Sunday.

Aphis Persicæ.—We are sorry that "X. Y. Z." has this pest in his orchard-house—at least we judge it to be so from his description, and still more sorry that smoking with tobacco, dusting with snuff, hellebore, &c., seem to have no effect upon it. That is contrary to our experience. The pest is easily killed if you catch it, and do not mind the appearance it gives to your fingers. We have never found it to stand a good smoking, nor dusting, or other modes; but then, though you kill all you see, and you think you have conquered him, lo and behold, the story of the Phoenix is a trifle to this beetle, as, if you leave a single one in hole or cranny, in the soil of the pot, or running round on the outside of it, you will not have to wait long until you have your thousands, or it may be millions, to again slaughter and destroy. We are also a little more unfortunate than "X. Y. Z.," as we have had the experience of last season as well as the present, and we believe it must have come to the place by some Peach plant or other, and heartily will we wish it good-bye when it takes its departure. In close houses where smoking can be resorted to, that we believe is the best mode for settling the plague. In a very close place, and where only a few plants are infested, bruised laurel leaves put in the place will not leave a single one alive. In an open orchard-house neither of these modes can be resorted to with anything like economy, unless either the whole house is covered, or individual trees are covered-in with a cloth which will keep in the smoke. In such a case, washings, and syringings, and dustings with powder are chiefly to be depended on; but nothing will do but constant watchfulness and perseverance, and with these the pest, if not thoroughly eradicated, will be kept down so as to be harmless; but the great thing is to be at him whenever he shows himself.

Besides this letter of "X. Y. Z.," we have several other letters complaining still more bitterly, and we fear if the pest becomes common it will give work enough. Most of these tell us the separate washes that have been used, such as old-fashioned clay, tobacco juice, sulphur, lime, and soft soap, Parmentier, Gishurst, 3 ozs., some more and some less to the gallon; and yet with all that trouble there is the enemy in black phalanxes ready to dispute the ground with them. We are sure a short article on the natural history of the insect, and some hints as to its destruction, would be useful. Although we have already given an outline of the treatment of these pests, we think we may shortly repeat it in order that it may be supplemented.

About this time last year the insects made their appearance; but they were kept down, and towards the autumn we could scarcely find a trace of them. To make assurance doubly sure, as soon as the leaves were falling we burnt sulphur in the house, thinking the fumes would kill everything alive and search into every hole and cranny. This killed some green points of shoots, which we expected, as we have long known that sulphur-burning will kill everything soft and green, but that it will have no effect on the buds of well-ripened wood if used in moderation. After this, when all the leaves, &c., were removed, several times during the winter the trees were well syringed with soap water as hot as the man could bear to use it with a cloth round the syringe. Then the trees were all washed with a brush and soap and water. The surface soil to the depth of $1\frac{1}{2}$ inch was carefully taken off, and afterwards the floor was watered with water not far from boiling, and in a few days stirred up and covered with fresh soil; then the trees were painted some time about Christmas, Gishurst, clay, and sulphur forming the paint, and working it well into every hole and joint and sluicing it among the buds, which were thus sealed up so far from the air for several months in the winter. One would imagine that such a doctoring would have found out every live insect, and most likely it did; but then we doubt if even very hot water will kill the vitality of eggs, and there is no doubt that, though these pests are produced in viviparous fashion, like ropes of onions in summer, shoals of eggs are laid in autumn, so that they may escape the casualties which would destroy the larvæ in winter. The whole of our washes, when trees are in a dormant state, have proceeded on the principle of sealing-up the eggs from air, and have, no doubt, thus done good; but until there is enough of heat to bring the principle of vitality into action, it is doubtful if the eggs are not as safe without air as with it, and the expanding of the buds will so cause the coating matter to crack that air will thus find its way to an egg if any such should be left. On this account, in some cases we have found a thin solution of glue one of the

most complete settlers for insects. Be this as it may, we saw no trace of our enemy until the buds and shoots were expanding, and, of course, a good portion of the paint in which they were enveloped had dropped off. Of course, the pest was attacked as duly reported.

On the trees we noticed two or three shoots rather bad on last Friday week; these were either removed or cleaned. On Monday these trees had a dingy black appearance, so thick were the insects scattered on the leaves and shoots. A decoction of tobacco-water and Gishurst and soft brushes were used, making sure that the wash was strong enough to settle the insects if it touched them, and not so strong as to injure the foliage. In washing, the hand was held as much as possible below the affected part to prevent the pests from dropping. Some, however, would do so, and as the work proceeded the ground was syringed with hot water. On Tuesday evening the trees were syringed heavily all over with laurel tea water in a clear state, being passed through a cloth, and the water heated to about 130° , the fruit being as much set as we believed rendered them free from danger. With water at this temperature, we have cleared away myriads of green fly; but, of course, it must not be so hot as to injure the plants. On close examination on Wednesday, among myriads of slain there were a few solitary specimens to be found in a sickly state, so at night another heavy syringing was given with clear sulphur-lime water at about the above temperature. This strong acid water is thus made:—One pound of flowers of sulphur and $1\frac{1}{4}$ lb. of quicklime are boiled half an hour in a gallon of water, say nearer five quarts. This when settled is as clear as sherry, and a quart of it was used for a barrel of thirty-six gallons of water, and that is pretty strong.

To-day (Thursday) we have not seen one alive, and to-night we will give another good syringing with clear water, and continue sprinkling as wanted. In such cases we would rather vary the means used than otherwise. We have more faith in perseverance, the use of the fingers, and constant watchfulness than in any one nostrum as a cure-all or kill-all in these matters. It is not seldom that we have seen men's names appended as testamentary evidence to the efficacy of certain mixtures in eradicating all sorts of insect enemies, and yet you could not walk through their houses without having your clothes encrusted with filthy insects that, of course, you never expected to find there. In close houses tobacco-smoking, with or without a few laurel leaves or capsicums mixed with it to make it more pungent, with the assistance of the syringe, we have no doubt will at last conquer this pest; but then the expense in large houses will be a consideration, and frequent applications will be necessary in order that too strong a dose may not injure the plants or bring the fruit rattling on the floor.

ORNAMENTAL DEPARTMENT.

Conservatory.—Re-arranged this, taking out lots of Chinese Primroses and Cinerarias; moving Azaleas in bloom more to the back to be slightly shaded, taking Pelargoniums to the front where they will have plenty of light, and placing lots of Cinerarias in bloom nearer the back, where they will be slightly shaded. When convenient, Cinerarias and Calceolarias will do better if set on damp moss, or if in saucers if the saucers are filled with moss. Next to freedom from frost, moisture and coolness are the great essentials of success and freedom from insects.

Potting.—*Camellia-buds Dropping*.—Many complaints have appeared during the season of Camellias dropping their buds, and in almost every instance we should be inclined to say that it arose from dryness at the roots, even though watering was given in the most systematic manner. In moving some Camellias from the conservatory to a vinery there were several that had not the right appearance, and the flowers were smaller than they ought to have been: we attributed it to dryness in the ball, and yet when the pot was well thumped with the knuckles it emitted a dull sound, as much as to say there is plenty of moisture there. Still the weight of the pot convinced us that the ball could not be wet enough. On turning the balls out of the pot we found this to be the case. No water had penetrated the centre for many a long day, never much from the time they had been last shifted. There are two little matters that young gardeners are difficult to be convinced upon—the first is, that young tender plants can be injured by taking them to a cold shed, shifting them in cold soil, and leaving them there an hour or two in the cold before taking them back to their warm place. The second is, the importance and necessity that every plant should be well

watered an hour or two before it is shifted into a larger pot, and more especially if the ball of the plant is but slightly broken or merely a little ruffled at the sides to let the roots out freely. Ever and anon men will be sure to stick dry balls into larger and fresh pots, and no amount of watering will ever saturate them afterwards. The water will pass through the fresh soil, avoiding the dry ball as if it were rolling from a cabbage-leaf or trickling from the wing of a duck. The only modes of moistening in such circumstances are either boring holes with wires in the ball, and filling these with water, or setting the pot overhead for half an hour in a tub of water. These Camellias we probed and brought out the dry dust from the centre of the ball to show there was no mistake in the matter, and before repotting them the ball was scoused overhead for a couple of hours in chilled water about 80°, and then allowed to drain before repotting. When any danger in this respect is apprehended the soil should not only be well firmed, but that next the pot should be rather the highest, to send the water over the bulk of the ball. We would advise in the case of all plants that throw their buds, or do not please in the flowering, that they should be examined in this respect, and care taken that the main part of the ball is not dry. There is just another fertile source of Camellias casting their buds, and that is the pots being cooled much by frost before the plants are housed. The roots are much more easily injured when expanded in a pot than when planted out.

FRESH SOIL.

We have potted-off a good number of Golden Chain Geraniums spring-struck, as we think that small young plants produce the best foliage. There is something rather tender in this still-general favourite. This winter our general stock has been kept in rather a low temperature. To have them nice they should rarely be below 45° in winter. They did not look so nice as we wished, or, being mostly in 60 and 48-pots, we would have turned the older plants into trenches with a piece of calico over them. On examination the plants seemed to have made few roots; and the soil being about them all the winter, it was not likely that it would be so sweet as to entice them to do so. Our intended treatment, therefore, was altered. A slight hotbed was made, chiefly of tree leaves. The plants were shaken free of the old soil, and replaced again in small pots in light soil, consisting of equal parts loam, leaf mould, peat, and sand, and plunged in a mild heat. In less than a week the fine white roots are getting to the sides of the pot, the leaves are increasing in size and yellowness, and in a fortnight they will stand anywhere and be fit to go out, and we feel confident in a favourable season they will do well. We are just as sure, that if kept in the pots in which they had been too much starved in winter, and in which the soil, owing to that coolness, had been slightly soured, the plants would have done little good until the ground had got warm in summer, and perhaps not even then. Most likely, too, they would have been as deficient in rich yellow as those mentioned by a correspondent the other week. This repotting, and a hitch on for a fortnight, will make them all that we wish—at least we hope so.

BEDDING PLANTS.

We have gone beyond limits; but we crave a few lines more, so that no mistake may be made, as it seems some misapprehension exists as to planting-out into temporary beds, which is a most economical plan where glass room is scarce, and would be advisable as a saving of labour up to the beginning of April, and putting the plants out singly. To amateurs, however, who either can pot singly or keep all they have in pots, we would advise them to do so after the middle of April is past. We have no glass for bedding plants, except what we use for other crops; and as we never think of potting a twentieth part, the earth-pit and the Celery-trench are our resorts after March, turning out the hardiest first. One fine feature of this system is, that instead of watering once a-day, once a-fortnight or once a-month is nearer the mark; and when the plants are to be moved short distances, we actually think the plants carefully lifted do better than when cramped in pots. After this 16th day of April, however, we would plant singly only such plants as form nice fibry roots. For instance: on a north border to-day we have pricked out a good many hundreds of the double white *Feverfew*, *grandiflora*, which is very hardy, but we like young plants best; and we cannot plant it out where it is wanted until we do so with *Ageratum* and Scarlet *Geraniums*, &c., when these plants will lift with nice balls singly. But now

after this time, unless we could give glass protection and a little help beneath the roots, we would not single out in a bed pots full of rooted cuttings of *Verbenas* or *Geraniums*, as they would receive a check, and would scarcely get well established in time. For all such things, however, we need the room they occupy, and most likely will need the pots several times over: and therefore, though it was only for a fortnight or a month we would turn them out into rough lumpy soil of which leaf mould formed a part, breaking the ball of the cluster of plants little or nothing. By this mode the fresh roots keep near home, the plants grow on without check, and a very little care at planting time enables you to divide the mass and plant separately; and individually they will suffer the moving but little. When obliged to economise room, means, labour-power, and command of water, many shifts must be resorted to; and the plan of turning out at this time lots of struck things just as they are is one of the best for us. Had we plenty of room under glass and pots, most likely we would pot a good many separately.—R. F.

TRADE CATALOGUES RECEIVED.

C. Turner, Slough. *General Spring Catalogue of Florists' Flowers, Bedding Plants, &c.*

Lucombe, Pince, & Co., Exeter. *Descriptive Catalogue of Roses, Softwooded Bedding Plants, &c., 1863.*

J. Scott, Merriott Nurseries, Crewkerne. *Descriptive Catalogue of Bedding Plants.*

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

AMERICAN GOOSEBERRY (*W. Chinnick*).—It is the Cape Gooseberry, *Physalis edulis*. The postage stamps were received.

CURRENT-BRANCH GRUB (*J. T. Jones*).—This is not at all an uncommon assailant. It is the larva of the Currant Sphinx (*Trochilus tipuliforme*). Not only the extremity but the entirety of a branch is destroyed by the grub eating the pith throughout its length. The brown grains are not eggs, but excrements. The parent moth, not the grub, lays the eggs.

LYCOPODIUMS (*M. H. K.*).—There is a work devoted to Lycopodiums.

AUSTRALIAN FLORA (*Tasman*).—A work on this Flora is announced by Mr. Lovell Reeve as about to be published, the author being Mr. Bentham, President of the Linnæan Society.

STOVE FERNS, &c. (*P. H. G.*).—The work is now printing. The plates are very numerous, and require great care. You can obtain the *Ailanthus* Silkworm eggs by writing to Lady Dorothy Nevill, Dangstein, Petersfield, Hants. The fronds of the Gold and Silver Ferns must not be sprinkled with water at all.

VENTILATING-PANE (*S. M., Bacup*).—There is no difficulty if a projecting lap of lead is fixed on the rafter over the upper half of the pane, and a similar flap is fixed on the lower half of the pane.

HAIRPINS FOR PEGGING PLANTS (*B.*).—If you require a large quantity, you had better apply to some wholesale house at Birmingham.

OXLIP (*J. W.*).—Whether it be an Oxlip or Polyanthus we cannot tell from seeing merely a truss of the flowers. Whichever it is, the limb of the corolla is larger, deeper in colour, and more sweet than any we remember.

CALADIUM ZEBRINUM (*W. W. W.*).—We conclude that the plant you have under this name is *Alocasia zebrina*. If so it requires stove culture, is a native of the Philippine Islands, and was imported last year by Messrs. Veitch.

PEAT SOIL (*H. B.*).—If you live near London, apply to Mr. Kennard, Swan Place, Old Kent Road. If at a distance and you require a quantity by rail, apply to Mr. Short, Reigate Heath, Surrey. You will see their advertisements in our Journal last week.

DWARF YELLOW CALCEOLARIA AND GERANIUMS FOR CHAIN-BORDER (*A Midland County*).—We have not seen any *Calceolaria* we like better than *C. Aurea floribunda*. The dwarfest Scarlet *Geranium* we have is *Little David*. One of the prettiest variegated varieties is *Queen's Favourite*. Dandy is the dwarfest, but it is a poor thing. Golden Chain is perhaps as good as any—certainly it is better than *Golden Fleece*. The white-edged class are so numerous that it is no easy matter to particularise. Countess of Warwick is admired by some, but we like *Jane*, *Bijou*, and *Alma* quite as much.

April 21, 1863.]

PROPAGATING FICUS ELASTICA, &c. (A Reader).—By cutting down a plant and cutting up the shoots into lengths of two eyes each, one to be under the sandy soil of the pot and the other above it, and keeping the cutting-pots in a warm frame, they will doubtless all strike. *Iberis corifolia* and dwarf *Cistus* may be both struck from cuttings in like manner if the cuttings were taken off when the young shoots are about 3 inches long. *Linum grandiflorum coccineum* comes best from seed.

PERTWINKLE (Garnons Gardens).—Not the same. Yours is purple, the other is double blue.

IVY PRUNING (J. S. Chorley).—Never clip Ivy; the cut leaves become brown and disfigure the plants. Have the shoots shortened-in as needed by the aid of a pruning-knife. Now is the best time for the operation.

POINSETTIA PULCHERRIMA PROPAGATING (A Subscriber).—Cuttings of two joints, one joint in the ground and one out; will strike freely in a hotbed, and the best time we have tried them is the end of July, as the plants then, and not get so leggy as they do when put in earlier. Keep them warm all through the growing season, and it is only after the crimson head is formed that the plant may be treated as a greenhouse one.

FIGS FALLING-OFF (A Subscriber).—Most likely your Fig trees in pots, standing, as you say, under the shade of Peach trees, either lack the necessary sun required to perfect the functions of impregnation, which in the Fig is different from that of other fruits; or, if the plants may have at any time lacked water, the same result will follow. Your remedy with the succeeding crop lies in trying to avoid these evils. Hard forcing at the particular time that impregnation is going on is fatal to the Fig; but the economy of the plant is wrapped in more mystery than that of most others. We may also say that in the growing season abundance of water is wanted, and neglect of this will occasion the falling-off you complain of.

PEACHES NOT SETTING (A Six-years Subscriber).—We can see no cause, unless extra dryness in winter and extra soaking when coming into bloom, which will frequently make the buds drop. From what you state, however, we incline to think that the trees were over-luxuriant and the wood not thoroughly ripened. We have had much the same happen with an Apricot tree. It was lifted two years ago; but last year the wood was vigorous, though not over-strong. When cutting it this spring we foretold the bloom-buds would do no good, and almost every one has fallen. There was no strength in them, for though large and flourishing in appearance, their attachment to the branch was very slender, and in most cases the germ or young fruit was wanting. We would advise you to pinch the wood more this season, and in September either lift and replant or root-prune, so as to secure more thorough hardening of the wood.

PROPAGATING-HOUSE (J. F.).—A place 7 or 8 feet wide and 40 in length, or say 10 feet wide and 30 long, would suit you. Now, this might either be a lean-to or a span, and both would be economical according to your material. If you had bricks, the cheapest would be—wall at back 8 feet, in front 4 feet, fixed roof, ventilators back and front. For bedding plants strike everything in autumn, and you would need merely a small flue to exclude frost. If you want to propagate in spring, perhaps it would be best to have hot water all round for top heat and below one bed at least for bottom heat. If we knew more of your needs and the materials at disposal, we might advise better.

DESTROYING SLUGS AND WORMS—PINE LEAVES DECAYING (A This-years Subscriber).—In the garden in the open places you might use a dusting of malt, enough just to whiten the ground, but a good liming would be the best remedy. Watering the lawn with clear lime-water would be the best and safest remedy. We think the brown spots on your Pine Apple leaves either have been caused by bruises by tying-up, or they have had a check of extra cold or damp, or both, in winter.

PLANTS FROM CEYLON (S. A.).—You can neither have the *Anæctochilus* nor the bulbs from Ceylon and Sumatra without trouble. We should be doubtful of the *Anæctochilus* unless taken up carefully and packed in a thick-glassed Wardian case and carefully attended to on the passage. The bulbs, too, must either be sent home with balls growing, or, what would be much better, marked where they grow and taken up when in a dormant state, in which condition they would come with least trouble. The more at rest the *Anæctochilus* are the safer will they come, but without care on the passage we should imagine there would be little chance of their doing much good afterwards.

LOBELIA KERMESINA—BEDDING-OUT (Q. Q.).—This *Lobelia* is generally stronger-growing than *Lobelia speciosa* true. It will do well for pin cushion beds, either with Golden Chain or Cloth of Gold, or even such white variegated ones as *Manglesii*, *Bijou*, *Alma*, &c. See what Mr. Fish said last week about pricking-out struck bedding plants in temporary beds. All autumn-struck are better for being pricked out separately. It is amazing what a difference the fresh soil does. After the middle and end of April Mr. Fish prefers turning out into such beds cuttings struck in pots just in lumps instead of singly. They thus receive less check, grow freely, and can be divided at planting with less care and trouble than by any other mode. If you could pit them, keep them under glass, and give every encouragement, of course, that would be better than planting-out under a rough protection, but then that suits the amateur who wants a few hundreds. Were some of us to do so we would need a Kelso for ourselves and a good village of glass houses. Much of your success, too, will depend on what your Vine shutter is. If it is board or thick canvass, we can account for its not answering—it would not be near so good as a piece of calico. If glass, the plants ought to have done better. We think the Golden Chain, when it does well, is still the best; but Cloth of Gold is much freer-growing, and has a fine soft feel, as it were, to the eye, and the flowers are a brilliant scarlet. See "Doings of Last Week."

LIST OF ANNUALS (Idem).—1, dwarf pot Poppy; 2, *Schizanthus pinnatus*; 3, *Clarkia integrifolia*; 4, *Chrysanthemum Burrigii*; 5, *Calliopsis pygmaea*; 6, *Portulaca*, mixed; 7, Ice Plant; 8, *Collinsia bicolor*; 9, *Oxyura chrysanthemoides*; 10, branching Larkspur; 11, *Erysimum Peroffskianum*; 12, *Gaillardia picta*; 13, *Gilia tricolor*; 14, *Delphinium Ajax humile*; 15, *Calliopsis bicolor*; 16, *Calliopsis cardaminifolia*; 17, *Phlox Drummondii*. As you want to know how these transplants, we may say that 1, 2, 3, 4, and 5 transplant tolerably well; 6, indifferently; 7, medium; 8 and 9, well; 10, very badly; 11, 12, and 13, pretty well; not so, however, 14, 15, well; 16, we do not know the variety; 17 likes a damp and rather peaty soil. Moist dull weather will enable you to transplant the whole with tolerable success, excepting the Larkspurs, which are best sown in small pots and transplanted whole.

EVERGREEN TO COVER A WALL (P. S. O.).—The wall being 3 feet high and in a damp place, we think that *Escallonia macrantha* is about the best plant that we know of for the purpose, as fast-growing plants are unsuitable. The place being damp and shaded, prevents many of the more showy shrubs being planted. Some of the *Berberis* might do; or a *Cotoneaster* looks not amiss, but best when allowed to ramble where it likes. With regard to perennials for a small garden, some of our Numbers for last year contain select lists of plants of this kind, which may, perhaps, suit your purpose. We are also promised an article on this subject from a correspondent.

ONE FURNACE FOR TWO FLUES (R. A.).—You can do as you propose with one furnace and dampers; yet we would rather have a separate furnace close to the other one for the separate flue. You may manage them together admirably yourself, but your stoker may not be so attentive.

VINES BREAKING PREMATURELY (J. Mackenzie).—In such circumstances we would allow the Vine to run without stopping, and give more expansion to the laterals. There is no rule without exceptions. The directions of Mr. Thomson are admirable, but in extreme cases he would vary them. It is of little consequence the few buds breaking; the shoots will yet get pretty strong, and will form good buds. We should not like *Musa Cavendishii* to be subject to a lower temperature than 50° in winter.

FLOWER-GARDEN PLAN (D. O.).—The left-side group will look very well, with one change. In place *Perilla* in the centre and *Cineraria* round it. We think the other side would look better if balanced in colour with the left side. There is no attempt to do this, and we think there will be a wearisome monotony by having all the beds filled or edged with light colours, as *Flower of the Day*, *Gnaphalium latatum*, variegated *Alyssum*, and *Mangles' Geranium*. We cannot do better than tell you to take a lesson from the left-hand side. The ribbon-border will do well.

FLOWERS OF SALVIA PATENS FALLING (G. D.).—Were it not for the flowers of this beautiful plant falling with the least rain, it would be invaluable for the flower garden, as we have no other blue-flowering plant to equal it. Heavy dews late in the season have the same effect as rain. There is one or two other blue-flowering *Salvias* less disposed to shed their flowers than this one, as *S. Grahamii* and another; but they are much inferior to *S. patens* in beauty; in fact, they are no better than some ordinary *Veronica*. We fear we cannot suggest a remedy.

LETTUCE SEED (G. A.).—Thanks. The seed has been sent to the parties you directed them to.

MANURE WATER FOR ROSES (Idem).—As you say farmyard manure water is not to be had, the next best is sewerage, which may be laid on tolerably strong, as the roots of *Roses* run much deeper than those of herbaceous plants, and consequently the sewerage is much filtered ere it reaches them. In default of sewerage, guano water will do. Generally speaking, *Roses* benefit much by a good dose of manure water after flowering, as it helps to restore them from the exhausted condition a heavy crop of flowers leaves them in.

PAINT FOR POSTS (A. Q.).—Nothing preserves either the end of posts inserted in the soil or the inside of plant-tubs, so well as charring them. Creosote would be as good as linseed oil in the mixture you mention. We should mix two gallons of hot (not boiling) coal tar with one gallon of creosote. The latter is poisonous.

ACACIA PROPAGATING (B. B.).—*A. armata*, *Drummondii*, *grandis*, and others strike freely from cuttings taken off the young wood when about 2 inches long and put into sandy soil in a hotbed. Many of the species also seed and reproduce themselves that way. The specimen you send seems to be *A. Hesterti*. The greatest enemy to *Acacias* is the white scale, which is very difficult to exterminate. If it be confined to the old wood a slight coating with sweet oil, laid on with a camel's-hair brush, is the best remedy we have tried, as it improves rather than deteriorates the appearance of the wood. Your *Cinerarias* were not better than many others already in cultivation.

ALOE FLOWERING AND OUTGROWING THE HOUSE (F. F.).—If you could turn the plant out and erect some covering that would shelter the flower from rain and extreme sun, and at the same time not shade the plant, it would continue in flower much longer than if fully exposed. The plant will bear all the cold we are likely to have; in fact, it is all but hardy. But if you wish to preserve the bloom in a state of beauty as long as possible, it must not be exposed to all weathers.

WHITE VARIETY OF VINCA MINOR (Sible Heddingham).—It is mentioned in "British Wild Flowers," published at our office. It is not uncommon.

INSECT IN ORCHARD-HOUSE (X. Y. Z.).—See "Doings of Last Week."

NAMES OF PLANTS (Constant Subscriber).—No. 1, *Stellaria holostea*; 2, *Caltha palustris*; 3, *Viola canina*; 4, *Arum maculatum*; 5, *Polypodium vulgare*. (*J. C. H.*)—1, *Ribes sanguineum*; 2, some *Berberis*, but the leaves are imperfect; 3, leaf only. (*J. D., Forfarshire*).—1, *Petasites vulgaris*; 2, *Mercurialis perennis*; 3, *Nepeta glechoma*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY-JUDGING IN PRESENCE OF THE PUBLIC.

PUBLIC attention seems at the present time more than usually directed to the judging of our general poultry exhibitions, and among the many new arrangements that have for a time been adopted and then proved useless, perhaps nothing has been suggested more fraught with objections than that of awarding the premiums in the presence of contending exhibitors. The principle is based on ground the most open to produce contentions of any hitherto known; for it would indeed be a matter of difficulty to devise a plan so well calculated to sow broadcast the very elements of dispute as the one just referred to.

I was present a short time back at a meeting where the system was fairly tried, and it was by no means an easy matter for any

casual bystander to determine who were the most deserving of commiseration, the Judges themselves or the disappointed competitors. Grouped within a few feet only of the arbitrators followed a throng, not only of parties curious to know the result, but still more so by those whose actual contending interests were strongly implicated in the decisions. It must be evident on the slightest reflection that where so conflicting desires for mastery exist, the usual routine of consistency will not be very rigidly adhered to where openly spoken and timely suggestions are hoped to warp the opinions of those officiating.

The impropriety of competitors requesting Judges to "reconsider" before making their final awards was thrown aside as useless etiquette, and the matter was at length so extravagant that cheers or murmurs followed the affixing of almost every card, whilst a corresponding measure of dispute and abuse not unfrequently broke out among the respective owners themselves, and in these latter cases blows seemed imminent.

I find that about five years since the same plan produced precisely the same result when reduced to practice, though then tried in very far distant localities.

I have not ever seen anything so productive of wrangling and dispute among exhibitors, or so utterly objectionable to arbitrators; nor would it be necessary to encroach on your pages had not application been made to several committees to adopt the plan complained of. Surely the awards at any exhibition should be so conducted as not to permit for a moment any interference with the officials, on whose deliberate and unmolested scrutiny so much depends. It is, therefore, in the hope to bring the matter more fully under the consideration of those interested in the perpetuity and welfare of poultry exhibitions that these few remarks have been indited by—AN AMATEUR.

POWTERS—A HINT.

EVERY lover of pets, whether of Bantams, Rabbits, Pigeons, or Hawks, or of the "smaller deer" Doves, singing birds, or white mice, residing in or near to Bath, any time between the beginning of this century and a few years since, knew "Old Hobbs, bird-dealer, No. 1, Trim Bridge," in that beautiful city. Perhaps my mention of this old man may revive in some of your readers the memory of a friend of bygone days. However that may be, I knew the old Hobbs but of some ten years ago. Far gone was he towards eighty—a thin, bent, small old man, with sharp piercing eyes, and aquiline nose, quaintly clad in short jacket and fur cap. He lived among his birds every day, and all day long, and so bird-like had he grown—to my eye, at least—that if I had found him some day in one of his larger cages quietly feasting on hempseed I should have been scarcely surprised. Poor old man! his life had been no path of roses. Sorely vexed was he, too, by intrusive boys who would hang over the half-door of his shop, and somewhat angrily did he rate them; powerless anger, alas! for the next minute they returned, eyeing the little shop all over, and criticising its inhabitants. A little short, and curt, and crusty was he also to new customers, but he had seen better days, to which, after I had become a crony of his, he was wont to refer with sadness: hence I held him excused, and I daresay every thinking person would.

"Such a pair of Pigeons, sir," he would say, "I used to sell for 30s. a-pair, and now I don't get 10s. for them; but no gentlemen keep the birds now, only schoolboys;" and then he would add bitterly, "and they make presents of them. There's no trade now-a-days."

But to my tale. I pitied the old man, and asked him to spend a day with me in the country, and never shall I forget his softened look. "Thank you, sir; very kind of you, but I can't leave them;" waving his hand towards his feathered and furred family. Forthwith we were friends; he always let me know if he had anything choice, and welcomed me with a smile. Now, I never knew old Hobbs' equal in knowledge of Pigeons. One day, standing before a cage of fine Blue Powters, I said, "Pity they wo'n't bring up their own young ones; for it makes keeping them so troublesome."

"Nonsense, sir, they will if there're only fed properly. Now, listen to me, sir; feed them on beans, and they will rear their young as well as any Pigeons."

It happened that a friend of mine bought these very Powters; they had several pairs of young ones, none of which they reared. He then fed them on beans, and I saw them some months after-

wards with several pairs of young ones parading in front of my friend's house. This, then, is the hint I beg leave to give to your Powter-loving readers. I myself have not been a breeder of Powters for some years. Even if the plan of bean-feeding does not answer with every pair, still, if it does with some, here is a gain: and if your knowing readers already know it, and smile at my want of knowingness, still, on all hands, I hope my motive for communicating this fact (a fact in one case at least), will be my full apology.

I the more readily send this, as in none of the Pigeon-books I possess, neither the old ones nor the two newer works, not even in that admirable and exhaustive one by Mr. Brent, "The Pigeon-Book"—the only one I know up to the present day—is the necessity of feeding Powters on beans mentioned.—WILTSHIRE RECTOR.

P.S.—Just let me add that a son of old Hobbs carries on, not unworthily, his father's business.

KEEPING DUCKS.

It is said that a nobleman on coming of age once asked in despair, on being told he had £50,000 per annum, "What could a man do with £50,000?" Many of our readers—and we hold the same opinion ourselves—think a great deal may or might be done. It takes our breath away to think of such an income. We fancy we would do nothing but good; we would restore the golden age to the place fortunate enough to be our residence; we would encourage virtue, put down vice, and keep lots of poultry. This puts us on our feet again. It is a common thing to hear the owner of a thousand acres lament his inability to keep more than one breed for want of convenience, and regret that he cannot keep Ducks because he has not a piece of water.

We have six poultry-houses on an acre of land. It is an orchard, crowded on two sides with trees. Each house is 12 feet long by 6 wide, 6 feet high in front, with a slated roof, slanting to 4 feet in height at the back. An enclosed space in front of each house is 21 feet long by 12 wide. Each house has a separate breed for tenants, and each has the run of the orchard for two hours every day. This involves no trouble. The fowls look for their liberty, and return cheerfully to their confinement. Of course the breeds are selected. They are Cochins, Spanish, Brahmas, and Crève Cœurs. We should not expect Dorkings to do as well. It is impossible for any birds to be in higher condition than these are. Their food is ground oats twice per day, whole corn given sparingly at midday, Indian corn once per week.

Now for Ducks. People imagine that a lake is almost a necessity for half a score of Ducks. It is a mistake. We keep a great many, and, protected by our incognito, we do not blush to say they have in the way of water only a ditch. This is, perhaps, 18 inches deep in places. This is all that is necessary. They enjoy it very much, they are in perfect health, they lay and breed well. The plain and sober truth is, that Ducks do not live on the water because they can swim, any more than birds live in the air because they can fly. Ordinary Ducks and Geese seldom take to the water except as a refuge. It is wanted for the condition and comfort of their plumage, it has much to do with their health; but for all necessary or useful purposes a puddle is sufficient, if it be 18 inches deep.

LARKS AND WAGTAILS.

ALTHOUGH the Larks, Pipits, and Wagtails have by naturalists been separated into three orders, still I think there is even more similarity between them than there is between some of those birds classed in one order as Finches.

Of the Larks proper we have only two species common in this country—the Skylark and the Woodlark; the Crested Lark, common on the Continent, is only a rare visitant to England.

Of Pipits we have more species, all of which are frequently confused under the common title of Titlarks. The commonest is the Meadow Pipit or common Pipit Lark, which, like the Skylark and Woodlark, remains with us all the winter. The next is the Tree Pipit, which is the true Titlark of the London bird-fanciers—a delicate bird much prized for its song, and which is migratory, passing only the summer months in this country. We have also the Rock Pipit or Shorelark, a rather local bird, more frequently found on the seacoast, and one or two others occasionally met with, but which can scarcely be called English birds.

Of Wagtails we have three species:—The Yellow Wagtail or Woolwhite, a tender migratory bird, which is not very common, and leaves us in autumn for a warmer clime; the Grey Wagtail, which has some yellow in its plumage and is often confused with the preceding, and which is more frequently met with, and remains all the winter; as does the common or Pied Wagtail, whose black, white, and grey pied plumage is well known, as well as its common names of Paddy Wash Dish, Dishwasher, or Water Wagtail. All these birds run on the ground—they do not hop. They are insect-feeding. Their legs are long, and the feet ill-adapted for perching. The tertiary feathers are long, forming a covering for the wings, in which respect they slightly resemble the Waders. The gradations of variation from the Skylark, through the Pipits, down to the common Pied Wagtail, are very gradual.

The Skylark is a very useful bird in the destruction of insects of many sorts. Wireworms are largely consumed by him, and he prefers the open fields, where tree-perching birds are less frequent. When hard pressed in cold weather he will eat a few small seeds and even oats when he can find them, if insect-food is scarce; but as his bill is not formed for seed-shelling, it is a great labour for him to extract the kernel from the husk, which feat he performs by pinching the oat at the base and beating it on the ground till he knocks it out. He will also eat a few blades of grass or leaves of clover: and hence some farmers foolishly blame the birds, never considering the great good they do in the destruction of insects that would damage an immense proportion of the crops, while the injury done by Larks is in reality a mere trifle. The Woodlark is more a bird of the waste and wild parts, though it often comes on the arable land. In food he is even more strictly insectivorous. His song is considered the most plaintive, wild, and flute-like of all birds, and by the fancier is even preferred to the merry carol of the Skylark.

Pipits are also useful birds, frequenting the commons, downs, meadows, and fields, and feeding on insects all the year round. The Tree Pipit or Titlark, however, prefers enclosed fields where trees or high hedges are handy, from which they collect caterpillars to feed their young on, and from which they spring into the air, rising almost perpendicularly to some height, when, stretching out their wings, they again descend, singing as they come down. Their song is appreciated by bird-fanciers, though I am not aware that they regard that of the other Pipits.

Wagtails are rarely kept in cages. They may be said to feed everywhere; but seem to prefer short pastures, where they play round the grazing cattle, catching the flies and insects disturbed by them, or along the margins of streams, where they catch the gnats and other insects which there abound. No fault can be found with these merry active birds that take neither grain nor fruit, and they should be always protected and encouraged. No wanton nest-destroying should ever be allowed by those who cultivate the soil. Birds are sent each in their respective place to keep in check insects that would otherwise entirely demolish all crops. What would then be our condition?

I am much in hope that the time is not far distant when this subject will receive the attention it deserves. At present insects are far too numerous, and often are complaints made of their ravages, and the failure of crops through their agency; and little is said of the thinning of many crops by agents which are, perhaps, often not even suspected, because they work under ground or unnoticed.

Birds are man's great allies, sent to feed on these his foes; and I feel that they have but small credit for their services, which are very great—quite incalculable, while if they do a trifling injury, or cause some annoyance, they receive an exaggerated amount of blame. Yes, even when seen looking for some insects they are not unfrequently blamed for the damage done by the very insect they are in search of. Being accessories after the act, or in suspicious proximity, is often sufficient condemnation. I must, therefore, use my pen in pleading the cause of the birds—not that I would deprive the schoolboy of his bird-nesting, or check the young naturalist in the bud. I see but little cruelty in taking the eggs from the nest while yet fresh laid if any use can be made of them; such, for instance, as a collection where care is taken of them, and only a few of each species are required, or it may be a poor child may take the fresh eggs to boil or to make custards of, or put in a cake or pudding. In such cases I see no more cruelty in the act than that of using the eggs of domestic poultry. But when boys, or even men, ruthlessly destroy every nest they find, whether hardset or containing young, then I consider it a wanton cruelty that should be checked in every

way. Or if an epicure likes Larks or Wheatears, or such small fry, I am not one of those who would object to his eating them in moderation. I see no wrong in a person killing a pair of each sort to form a stuffed collection, or catching them to keep a living one, to enjoy their song, or watch their habits. I believe that all things are given for man's use; and if boys like to catch Sparrows to convert into a pudding, I would not say them nay. But wholesale destruction of birds for the mere sake of killing, vindictive poisoning, and indiscriminate nesting, I think shows a cruel and ignorant mind which calls for reprobation.

Few birds, even those thought to be destructive, do a tithe of the injury laid to their charge; for an ignorant person, annoyed at some trifling loss which a little forethought might have saved, often, I fear, retaliates on the birds for his own neglect. Such an one will use poison or advocate indiscriminate bird-murder, and he assuredly will cause greater loss another season to himself and neighbours by the rapid increase of insects. These proceedings are what I wish to deprecate, and I fear they are too common. To say the least of it, such a course is "penny wise and pound foolish." It is here I must apply to the prejudiced. If they could but perceive the loss they bring on themselves, and perceive the cause and effect, the breeches-pocket account would be the most convincing argument.—B. F. BRENT.

BEE-FEEDING.

Is "AN AYRSHIRE BEE-KEEPER" right in hinting that our friends on the north side of the Tweed are so addicted to the use of the bottle that they begrudge it to their bees? Never having crossed that famous stream, I cannot myself determine the question; but this I can say, after a most thorough trial of the bottle, it is the best bee-feeder ever contrived. During the last three bad seasons I must have administered upwards of a ton of food by its means without the slightest accident, or the least inconvenience. Recent observation in a friend's apiary leads me, however, to advise that in all cases where a wide-mouthed bottle is used, a piece of perforated zinc should be interposed; as if this be omitted, and the top of the hive be not perfectly level, the food is apt to run out.—A DEVONSHIRE BEE-KEEPER.

MORTALITY OF HIVES.

As in the communities of men so in the communities of bees, the influences which affect their welfare, either for good or evil, often date long prior to the results which flow from them. The year 1862 was notoriously the most adverse for bees which has been experienced for a long period back, while the two preceding years were scarcely much better. A series of unpropitious seasons thus following each other in close succession, the autumn of 1862 witnessed a state of matters lamentable to contemplate, and which the experienced apiarian knew well would in due time be productive of those dire evils and calamities which are now being felt with such awful severity throughout the whole length and breadth of the land. And what was the state or condition of the great majority of hives at that season? Why, they were in every respect in the most unsatisfactory state possible. They lacked what I consider to be the three great and essential requisites which constitute a thoroughly good colony—namely, sufficiency of bees, sufficiency of food, and a perfectly and permanently prolific queen. The consequences are that from one or other of these causes the mortality of hives this spring is immense. Whole apiaries, in many cases, have become completely extinct, while here and there in every bee-keeper's garden may be seen the sad evidences of disaster and ruin; and such has been the unfavourable nature of this season up to the period I write (10th April), that unless good weather set in without delay, a third of those which still survive will droop away and die, or become eventually good for nothing. One of your correspondents prophesies in No. 106, that "we shall have a fine summer for honey if only we have a dry and cold six weeks before us." All I can say in regard to this prophecy is that if the fine honey season in prospect cannot be had without the preliminary six weeks of cold, I fear we shall have few bees to enjoy it, and that the opening flowers of the looked-for summer will be doomed, so far as the bees are concerned,

"To blush unseen,
And waste their sweetness in the desert air."

But let us hope for better things. A speedy change of weather

will prevent this evil, while a continuation of the present cold dry weather will be utter ruin to many weak hives still holding out hopes of recovery.

One of the reasons which I have above assigned for the ruin of not a few hives this spring refers to the imperfect fecundation of the queen. One form or manifestation of this abnormal state is alluded to by your correspondents "B. & W." and "A DEVONSHIRE BEE-KEEPER" in the Journal of April 7, in the case of such queens as produce only drone-brood. Whether we refer this abnormal condition of the queen to the Dzierzonian doctrine of "parthenogenesis" or the Huberian theory of "retarded impregnation" is of little consequence so far as results are concerned; for I suppose we are all agreed as to the uselessness of such queens.

I observe that both of the correspondents alluded to intend to avail themselves of the drone-brood thus produced as helps in the process of artificial queen-rearing. If I might presume to give an opinion in the matter, all I can say is that I would have very little faith in such questionable helps. I do not know what sort of drones are produced in the apiaries of these gentlemen by such conditioned queens, but those which I have seen produced in like circumstances are generally extremely puny and often malformed from being bred in small cells; and if the followers of Dzierzon, like their master, look upon the most perfect of the drone species, even as imperfect creatures, "for the production of which," as Dzierzon says, "fewer conditions and forces are necessary than for the production of the more perfect beings the females," then certainly such puny-looking things as are generally produced by drone-breeding queens must be held as perfect monstrosities. But be this as it may, I should not, I repeat, put much reliance upon their aid in queen-rearing, and I suspect that little benefit will result from preserving them, if, indeed, they can be preserved so long; and that experience will show that towards the attainment of the object desired with respect to queen-rearing, there is something more required than the mere presence of such suspicious-looking and questionable agencies.

I shall, perhaps, at some future time, enter more minutely into a consideration of the three points I have mooted above as constituting the three essential requisites of a good colony of bees. Each of these is important in itself, and if the apiarian would only properly appreciate the importance of each of these requisites and foresee the evils the want of any one of them is sure to produce, he could with greater reliance in the autumn set apart such well-conditioned hives for stock as would, in all probability, not only survive the perils of the winter but the greater and more trying perils of the spring.—J. LOWE.

UNITING BEES.

I COMMENCED bee-keeping last season, my stock comprising a Nutt's wooden hive (two years old), one square wooden box, and one straw skep. The three hives being very heavy and full of bees, by September my stock had increased to eleven, and on the 8th of that month I weighed them, including the footboard.

	lbs. ozs.		lbs. ozs.
No. 1	51 8	No. 6	19 8
No. 2	32 0	No. 7	15 8
No. 3	32 0	No. 8	35 8
No. 4	30 0	No. 9	15 0
No. 5	40 0	No. 10	23 8

The Nutt's hive I could not weigh. The next morning I administered chloroform (one drachm to each hive) to the five weakest hives, 4, 6, 7, 9, and 10, destroying the queen, and placing the bees in an empty straw skep, with perforated zinc at top, and coarse cloth at bottom, to allow the fresh air to revive the bees, and at night placed each hive on the top of 1, 2, 3, 5, and 8, having first smeared a little honey on the top of each of the latter hives. There appeared no fighting, and I do not think that I lost more than a quart of bees, and took from 20 to 30 lbs. of honey.

Having been away from home, I have delayed weighing my hives a fortnight later than I could have wished, but this is the result this day.

leaving me four hives (besides Nutt's) immensely strong, proving the folly of destroying the life of these valuable insects.—A GUILDFORD BEE-KEEPER.

DO LIGURIAN BEES SUCK THE RED CLOVER?

I AM informed that it has been stated, that where the Italian species of honey bee has been introduced, it has been found that they suck the common red clover which, it is well known, is commonly neglected by the ordinary hive-bee. I shall endeavour myself to determine the point during this season, but as red clover is somewhat scarce in my immediate neighbourhood, I shall be very glad of the assistance of other observers where the Ligurians have been established. One caution is, however, necessary, since it is stated that after the clover is cut the flowers of the second crop are a little shorter than those of the first, and, therefore, common bees can suck them; also, the flowers of the second crop (and, perhaps, those of the first), are very often perforated near their bases by bumble bees, and they are then sucked by hive bees, so that it is necessary to note whether the bees suck at the base or at the mouth of the flowers.—A DEVONSHIRE BEE-KEEPER.

BEE FOOD.

COULD any of your correspondents inform me if ever they have tried the feeding of their bees with infused hops? I have fed them these number of years with them, and consider it a great improvement. The quantity I use is about $\frac{1}{2}$ oz. to 1 lb. of sugar. The bees take it readily, preferring it to sugar alone.—W. T. BLANTYRE.

CARROT SOUP.—To seven pints of soft water put one pound of lean beef cut thin, half a pint of split peas, one large carrot cut into pieces, one or two turnips, some celery, and a large onion. Boil all together until the liquor is reduced to one-half the quantity, then strain it through a coarse hair-sieve. Have ready three or four large carrots, half-boiled and grated fine, put this into the soup; boil it with pepper and salt to your taste. Just before it gets to the last boil, take a little fresh butter, about the size of a walnut, rubbed in flour, and put into the soup. Serve it up with fried bread. If more soup is wanted, all the ingredients must be doubled, with the exception of the grated carrots; and, if they are large, six will be found sufficient for a good-sized tureen.

OUR LETTER BOX.

WORK ON PIGEONS (*H. F. B., Castleton*).—You can have, free by post, Brent's "Pigeon-Book" from our office if you send your direction with twenty postage stamps. It fully describes the different kinds, and gives a woodcut of most of them.

INCUBATOR (*A Young Amateur*).—You might obtain one, perhaps, by advertising for it. We know of no maker now. Stable-manure varies very much in the temperature to which it gives birth, and the duration of that temperature. It is too uncertain for hatching purposes, as a regular temperature of 105° or 106° is required. Your Duck egg is probably double-yolked, and the occurrence is not unusual.

LAMENESS IN DUCKS (*J. H.*).—We attribute the lameness principally to the brick floor. It is bad for all animals with long nails at the end of their toes. All Gallinaceæ and Game straw does not help much. Do away with it, and substitute loose gravel 4 or 5 inches deep. The run in grass is good, especially when the dew is on it in the morning; but a thorough wash is wanted at times. You need not make a large and expensive pond, but you may sink a washing-tub, and that will give all the water that is absolutely necessary. They cannot do without that.

DUCK EGG-BOUND (*An Amateur Duck-breeder*).—She is too fat, and the egg-passage is inflamed. Give her nothing but mashed potatoes mixed with a little barleymeal as food; and a tablespoonful of castor oil, and a pill containing two grains of calomel and one-sixth of a grain of tartar emetic every second day, until the symptoms subside.

ADVERTISEMENT (*Colchester*).—The charge would be 3s. 6d.

PURCHASING BEES (*F. Davis*).—You had better buy a swarm of some bee-keeper in your own neighbourhood. Prices vary considerably in different localities.

ROSSELLE PAROQUETS NEARLY FEATHERLESS (*M. G., Croydon*).—If your birds have neither cold, nor are too fat, nor have been fed on animal or greasy food, the cause of their losing their feathers from the breast and other parts is owing to their blood being overheated, which causes an irritation of the skin, and consequently the birds nibble their feathers off. We would recommend you to endeavour to wean them off the hempseed, and give oats, soaked overnight, and canary seed; also a little soaked bread, with plenty of fresh watercress, but no animal or greasy food of any description. Take care that the birds feed, as you will have some difficulty in weaning them from the hemp, which should be done by degrees. With a fine-rose-headed watering-pot give the birds a bath twice a-day when the weather is mild, taking care to have the water lukewarm; also place a pan of water in the cage.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 61.2° and 38.7° respectively. The greatest heat, 81°, occurred on the 28th, in 1840, and 4th in 1833; and the lowest cold, 13°, on the 29th, in 1861. During the period 158 days were fine, and on 94 rain fell.

GARDENERS' BENEFIT SOCIETY.

ALTHOUGH gardeners are a long-lived class, yet their labour being heavy and their exposure to sudden vicissitudes of temperature very frequent, they are among the classes who are most liable to rheumatism and other illnesses temporarily incapacitating them for labour.

Gardeners, therefore, from these causes, and from the generally low rate of wages they receive, are of the number who especially require occasional money aid; yet being also

especially liable to change their situations, they are consequently restrained from becoming members of local Friendly Societies.

Other societies, usually called benefit clubs, are chiefly beneficial to the landlords of the inns where they hold their meetings, and too often induce some of the members to spend as much in drinking and smoking as they have to contribute to the club. Nor is that the only objection to such clubs; for being founded on erroneous principles, or upon no principle at all, the funds too often fail, and the contributor's money has been expended without any benefit to himself.

The usual principle, or rather no principle, of such clubs is, that all the members pay an equal weekly sum to the fund. The unfairness of this to the younger members is demonstrated by the indisputable fact, that the older members are liable, on an average, to exactly twice as many days of sickness in the course of a year than are the younger members.

Mr. Finlayson, Actuary of the National Debt, made a report to the House of Commons upon this very point, and after examining and comparing the returns made from all the Friendly Societies throughout the kingdom to the Registrar appointed by Act of Parliament, he states,

"In the case of heavy labour the average amount of sickness is:—

In the first twenty-five years of labour, from the age of 15½ to 40½ . . . 189½ days.
In the next twenty-five years, from the age of 40½ to 65½ . . . 391½ days."

Other results from the light-labour classes coincide with this, and Mr. Finlayson concludes by saying, "These results indicate a law on this point, and to establish the conclusion that the sickness undergone during the first twenty-five years of working life, is the exact half of that undergone during the second twenty-five years."

Therefore, as regards the individual, it is clear that where a member included in the first period pays 1s. to secure a sick allowance, a member included in the second period must pay 2s. to derive the same allowance and sustain the funds of the Society.

Although for the sake of arriving at this valuable statistic No. 109.—VOL. IV., NEW SERIES.

tical information, the subscribers to Friendly Societies have been divided into only two periods of twenty-five years each, yet the returns from the kingdom's societies from which that information is derived, shows that every year of labouring life averages a different amount of sickness, gradually increasing as age increases. Upon those returns Mr. Finlayson has calculated a set of most trustworthy tables, showing the monthly payment a man engaged in heavy labour ought to make, commencing at any age after 14 years, to secure to himself an allowance of 10s. weekly during sickness until he has attained the age of 70, 65, or 60 years.

Taking the limit as 70 years, then if he becomes a member at 15 years of age, he would have to pay 1s. 2d. monthly; if he begins at 30, then 1s. 6d. monthly; and if at 45, then 2s. 1d. monthly. This is omitting fractions of a penny, and making no allowance for the expense of managing the Society.

That management requires care and circumspection. Diseased and broken-constituted members have to be excluded, and unfounded claims have to be checked.

When the age of 70, 65, or 60 years, whichever of those three periods a subscriber has selected, has been attained, then another aid of a benefit Society is available, which provides a weekly payment for the remainder of the subscriber's life. This is quite independent of the allowance-in-sickness fund, and requires an entirely separate subscription.

Mr. Finlayson from the source of indisputably sound information above referred to, has returned to the House of Commons a set of tables, showing for what monthly payments a pension of 5s. per week can be secured, to commence at the age of 70 years, 65 years, or 60 years.

If the gardener, for example, wishes, to secure such a pension when he attains 70, and begins to contribute for it at the age of 15 years, he must pay 6d. per month; if he begins at 30 years, 1s. per month; and if at 45 years, 2s. 6d. per month.

Consequently, in such a benefit society a gardener beginning when 15 years old to pay to its funds 1s. 8d. a-month, may secure 10s. per week during sickness until he is 70; and 5s. per week for the remainder of his life. If beginning to subscribe when 30 years old, 2s. 6d. per month will secure to him the same payments; and if beginning to subscribe when 45, then 4s. 7d. must be his monthly contribution.

The preceding are the chief objects of a Gardeners' Benefit Society so far as its members are concerned individually; but there is another function employable by such a Society for the benefit of the community, whether they be gardeners or the employers of gardeners.

Such a Benefit Society could only be managed by a Board of Directors and a Secretary. Those Directors should be men identified with gardening, and in whom all gardeners have an entire confidence. Those Directors might have periodical meetings for the examination of any gardeners who chose to appear before them, and to whom the examiners might grant a first, second, or third-class certificate, according to a previously announced

No. 761.—VOL. XXIX., OLD SERIES.

standard. A register of all such certificated examiners to be kept at the Society's office; the value of a power to refer to which would be apparent both to the employer and the employed. Having thus particularised the objects as well as the foundation on which a Society so desirable should be established, with a certainty of its being permanent, we will next consider the form and rules which we consider it should adopt.

As a trustworthy guide in this, we have selected for a basis the Hampshire Friendly Society, which, founded as long since as 1825, is now prospering, and after during thirty-eight years meeting all claims upon it promptly and liberally, has now invested in public securities more than £31,000.

PATRON.
VICE-PATRON.
PRESIDENT.
VICE-PRESIDENT.
TRUSTEES.
DIRECTORS.
ARBITRATORS.
AUDITORS.
HONORARY PHYSICIAN.
HONORARY TREASURER.
SECRETARY.

Rule 1.—The object of the Gardeners' Benefit Society shall be to raise, by the contributions of its members, a fund for the relief of its benefit members in sickness and old age.

Rule 2.—The Society shall consist of benefit and honorary members resident in the United Kingdom.

Rule 3.—Benefit members shall be those who contribute either for themselves or others, in order to obtain any benefits for which provision is made by the tables of the Society.

Rule 4.—Honorary members shall be those, who, not being benefit members, contribute not less than £5 by donation, or 5s. by yearly subscription.

Rule 5.—The Society shall be under the management of a Central Board, which shall consist of the following officers: the President and Vice-President, who shall be honorary members, five Directors, three of whom shall be benefit and two honorary members, eight Trustees who shall be honorary members.

Rule 6.—The other officers of the Society shall be a Treasurer, a Secretary, four Auditors, and an Honorary Physician.

Rule 7.—The President, and, in his absence, the Vice-President, shall preside at all meetings of the Society, of the Central Board, and of any Special Committee; and shall have a casting vote in addition to his own. In the absence of both President and Vice-President, a chairman elected by the meeting shall preside with the same powers.

Rule 8.—The Trustees shall from time to time invest all monies which may not be required for the current expenses in real or Government securities; or, with the consent of the Central Board, in such other ways as are in accordance with the provisions of the act 13 & 14 Vict., c. 115; and such funds may be transferred, or withdrawn, as the Board may direct, for the use and benefit of the Institution, upon the authority of not less than two Trustees, whose signatures to that authority shall be duly attested.

Rule 9.—The Treasurer shall be responsible for such sums of money as may from time to time be placed in his hands on account of the Society, and for the investment and application of them under the authority of the Central Board, or Trustees, as the case may be, in such manner as not less than two of them, whose signatures shall be attested by the Secretary, shall in writing direct. He shall balance his cash accounts quarterly, and supply the Secretary with a duplicate thereof.

Rule 10.—The Secretary shall transact the business of the Society under the direction of the Central Board; he shall attend all the meetings of the Society, and of the Central Board; he shall keep all the books, of which, together with all documents, he shall have charge. His salary shall be such as shall be fixed by the Board.

Rule 11.—The Auditors, any two of whom shall be competent to act, shall examine the accounts of the Society quarterly, and report the same to the Trustees and Central Board; they shall prepare a general statement of the funds and effects of the Society up to the 31st of December inclusive in each year, specifying in whose custody the said funds and effects shall be then remaining, together with an account of all sums of money received and expended by, or on account of the Society since the publication of the preceding report. Every such statement

having been attested by two Auditors, and countersigned by the Secretary, shall be presented at the general annual meeting, together with the report of the Central Board; and this statement and report, if approved of by such meeting, shall be printed, and every member shall be entitled to a copy free of expense.

Rule 12.—The Honorary Physician shall examine and report upon all Medical Certificates referred to him by the Central Board.

Rule 13.—The Treasurer, Secretary, and Local Agents shall give such security as the Central Board may require, pursuant to Act of Parliament.

Rule 14.—An Annual Meeting of the members shall be held at London on the third Wednesday in April, at which every member who is not in arrear of his contributions, fines, or subscription, shall have one vote; due notice shall be given of such meeting in two at least of the London newspapers, and two at least of the London gardening journals. At this meeting the members shall consider the financial statement of the Auditors, and the report of the Central Board. They shall elect for the ensuing year, the President, Vice-President, and Directors; they shall also appoint the Auditors, and fill up vacancies among the Trustees; and take into consideration any other matter connected with the welfare of the Society.

Rule 15.—The President, or Vice-President, on a requisition signed by ten members, shall summon a Special General Meeting of the Society: in each case five days' notice shall be given by circular, which circular shall state the object of such meeting; and at such meetings no business shall be transacted except that specified in the notice. At all meetings of the Society, general or special, except in the case of alteration of the rules, five shall be a quorum.

Rule 16.—The Central Board, three of whom shall be a quorum, shall meet at London every Saturday. They shall appoint the Treasurer, Secretary, and Honorary Physician. They shall accept or reject the proposals for payments in sickness, which shall be transmitted to them; and provide for the payment of all sums due from the Society. They shall, on the second Saturday in every month, examine the books and accounts of the Society, and decide upon all other questions that may be referred to them; and they shall, every quarter, take into consideration the Auditors' Report.

Rule 17.—If within half-an-hour of the time appointed for holding any meeting of the Society, or of the Central Board, a sufficient number of members to constitute such meeting be not present, the Secretary of the Society shall have power to adjourn the meeting to such time as to him may seem expedient.

Rule 18.—Any person wishing to become a benefit member of the Society, shall satisfy the Directors as to his character, obtain the recommendation of two benefit members, fill up the forms adopted for the admission of members, and make a deposit of one monthly contribution, which shall be returned to him if he be not admitted. He shall give such proof of his age as the Directors shall think fit, when the payment required from him is governed by it; and if his proposal be for an allowance in sickness, he shall produce a certificate of good health from a surgeon: provided always that when he is unknown to the Surgeon, he shall produce an additional certificate from some other medical man who is acquainted with him and his family; but if there be none such, then from such other person or persons as the Directors may consider competent to give one.

Rule 19.—The monthly contribution of a member shall be due on the day on which his proposal is dated, and on the first Monday in every succeeding month. If all contributions be not paid within a month of the day when due, he shall pay a fine of sixpence for every month they shall continue unpaid; and, if at the end of three months, such contributions, with all fines due, shall remain unpaid, he shall forfeit all claim to the insurance for which the contributions are due. But if such arrears shall have been occasioned by absence from the United Kingdom, the member may, on discharging within six months after his or her return, all arrears with compound interest thereon at £3 5s. per cent. per annum, be again enrolled at the same rate of insurance as before; provided that every such member, if insuring an allowance in sickness, shall have no claim for such allowance on account of any sickness occurring during his absence, and shall, before his re-enrollment, prove the goodness of his health in the same manner as on his first admission into the Society.

Rule 20.—Every member shall, in addition to his monthly

contribution, pay for management, the sum of 2d. a-month, or 2s. annually at Michaelmas. Every member insuring for sick-pay, shall also pay, if required by the Directors, but not otherwise, 4d. a-month, or 4s. annually at Michaelmas, to insure for medical attendance and medicines: and those members who are not so required by the Committee, shall pay 2s. 6d. at entrance, to the Society's Medical Officer for his certificate. Nevertheless it shall be competent for the Directors, if they shall think proper, to make arrangements for the payment of their own Surgeon and Agent; provided always that no benefit member shall in any case be called upon to pay more than 6s. a-year in all for Surgeon and Management.

Rule 21.—All honorary subscriptions shall be considered due on the 1st of January for the year ensuing. They shall be appropriated annually towards the redemption of the payments for Surgeons and Agents due for the current year, and all surplus shall be for the general expenses of the Society.

Rule 22.—That if any dispute shall arise between any member or person claiming under or on account of any member, and the Trustees, Treasurer, or other officer of the Society, or the Directors thereof, it shall be referred to arbitration, 10 Geo. IV., c. 56, s. 27, 28. At the first meeting of the Society after these rules are certified by the Registrar, five Arbitrators shall be named and elected, none of them being directly or indirectly beneficially interested in the funds of the Society; and in each case of dispute the names of the Arbitrators shall be written on pieces of paper and placed in a box or glass, and the three whose names are first drawn out by the complaining party, or by some one appointed by him or her, shall be the Arbitrators to decide the matter in difference. In case of a vacancy or vacancies, another or others shall be elected at a General Meeting.

Rule 23.—If any member shall be convicted of felony, or shall resort to any grossly immoral practice for a livelihood, or shall have wilfully imposed on, or attempted in any way to deceive or defraud the Society, or shall be aware of any such attempt on the part of another member, and not communicate the same to the Directors, he shall be expelled from the Society, and thereby forfeit every claim upon it, unless on an appeal to the Board they shall direct otherwise.

Rule 24.—No member who is a minor shall be capable of holding office in the Society.

Rule 25.—The Rules of the Society shall be printed, and every member on his admission shall purchase a copy, for which he shall pay threepence.

Rule 26.—All assurances for sick-pay shall be contributed for according to the rates laid down in the following tables. Nos. I. and II.

[We do not insert the tables because they are lengthy.]

Rule 27.—A member claiming sick-pay shall give notice in writing to the Directors, who shall provide him with a form of medical certificate, to be signed by the Surgeon attending him. The sick-pay shall become due one week after the date of the Surgeon's certificate, and be payable upon the production of the sick-pay paper, to be also furnished by the Agent, and to be signed weekly, on the day or days of their visiting him, by the Surgeon and by one benefit member, if the sick member be at the time residing within any district of the Society. When a member is not entitled to the attendance of the district Surgeon, he shall obtain the attendance of some duly qualified medical practitioner, and the certificates shall in such case be countersigned by the officiating clergyman of the parish, or by a magistrate of the county in which such member resides.

Rule 28.—A member shall be entitled to full pay when he shall be wholly unable to work, and to half pay when able to earn a little, but unable to follow his customary employment: provided always that any member who during the course of twelve successive months shall have received twenty-six weeks' full pay, shall then be reduced to half pay, and shall not be entitled to full pay again during any further sickness until he has for twelve successive months ceased to receive sick-pay at all.

Rule 29.—Sick-pay shall not be due to any member who has not been such for nine calendar months, unless he shall pay down an entrance fee equal to six monthly contributions, when he shall become free immediately; or to any member whose contributions or fines are in arrear; or to any member whilst he is suffering from any disease or infirmity with which he may have been afflicted at the time of his admission into the Society, or which may have been contracted afterwards by profligacy, drunkenness, quarrelling, or any act whatsoever contrary to law;

or to any member whilst confined in any gaol or bridewell, except it be on account of debt, and then one-half of the sick-pay which would have been otherwise due to such member shall be allowed to him; or to any member whilst at sea, or beyond the limits of the United Kingdom; or to any member who shall allow his sick-pay to remain unclaimed for six weeks; or to any member who shall refuse to answer any questions respecting his health or employment, put to him by any officer of the Society, or be seen to do any work whilst claiming full sick-pay, or be at any public-house or beer-shop, or leave home without the consent of the Surgeon, or shall by any wilful act or misconduct prevent or delay the recovery of his health.

Rule 30.—No person shall insure for sick-pay which together with any sick-pay insured in any other benefit society shall be greater than 20s. a-week, or more than his average earnings.

Rule 31.—No person shall be admitted to insure for sick-pay whose employment in the opinion of the Medical Officer tends to induce disease: and should any member who is insured for sick-pay change his employment, he shall give notice of the same to the Agent within a month; and if the Medical Officer shall be of opinion that the new employment has more than a common tendency to induce disease, then the Directors shall require him either to leave such employment or change his insurance to another table; and if he refuse to do either, the Directors shall have power to adjudicate on the case, and, if necessary, expel him from the Society.

Rule 32.—All insurances for annuities shall be contributed for according to the rates laid down in the following tables:—

[We do not insert the tables for the reason above specified.]

Rule 33.—No person shall insure for an annuity which together with any annuity insured in any other benefit society shall be greater than £30 a-year.

Rule 34.—Annuities which are due weekly may be paid weekly, monthly, or quarterly, at the discretion of the annuitant; but if any payment be unclaimed and left in arrear for a twelvemonth it shall be forfeited.

Rule 35.—Any member to whom an annuity is payable shall forward to the Secretary proof of his identity, according to the form provided by the Society, signed by the officiating minister of the parish, or by a magistrate of the county in which he is residing.

Rule 36.—That a book or books be kept in which all monies received or paid on account of any particular fund or benefit for which the rules of the Society provide, shall be entered in a separate account, distinct from the monies received and paid on account of any other benefit or provision. 9 & 10 Vict., c. 27, s. 4.

Rule 37.—The accounts of the Society shall be laid before an Actuary every five years, or oftener, if thought advisable by any general meeting. If the report of the Actuary show a nett surplus, the interest of such surplus shall be applied to the expenses of management in such manner as the Central Board may direct.

Rule 38.—The returns of the rate of sickness and mortality required by law to be sent by every Friendly Society at intervals of five years, shall be sent to the Registrar of Friendly Societies in England, according to such form as shall be prepared for that purpose by the said Registrar, under the direction of one of Her Majesty's principal Secretaries of State; and with every such return shall be sent a report of the assets and liabilities of such Society.

Rule 39.—The Treasurers, Trustees, Stewards, or other principal officer of every such Society, who by the rules of such Society are or is bound to prepare, or cause to be prepared, the yearly general statement of the funds and effects of such Society, shall be the persons who shall be respectively bound to make, or cause to be made, and to send to the Registrar of Friendly Societies the said returns of the rate of sickness and mortality, and the said report of the assets and liabilities of such Society; and every such person who shall refuse or wilfully neglect to make, or cause to be made, or to send the said returns of sickness or mortality, or the said report of the assets and liabilities of such Society, at the time and in the manner prescribed by the said Acts, or this Act, shall be liable to a penalty not exceeding the sum of £5, to be recovered, with costs, before any two justices of the peace having jurisdiction where such Society shall have its place of meeting, and, on non-payment thereof, the same, with the reasonable costs of conviction, shall be levied by distress and sale of the goods and chattels of the offender or offenders, by warrant under the hand and seal of such justices. 9 & 10 Vict., c. 27, s. 6.

Rule 40.—This Society shall not be dissolved otherwise than with the consent of five-sixths in value of the then existing members, and the consent of all those receiving or entitled to any benefit agreeably to 10 Geo. IV., c. 56, s. 26.

Rule 41.—That in case of any alteration in the place of meeting or dissolution of this Society, notice shall be sent to the Registrar of Friendly Societies in England, seven days before or after such removal or dissolution, signed by the Secretary or other principal officer, and also by three or more of the members of the said Society.

Rule 42.—No alteration of the Rules shall be made, except at a general meeting of the Society specially called for that purpose, pursuant to 18 & 19 Vict., c. 63, s. 27, notice of which, specifying the nature of the intended alteration, shall be given twice at least in two or more of the county papers.

We have thus detailed our opinions relative to the need there is for a GARDENERS' BENEFIT SOCIETY, as well as the basis and rules on which it should be established and by which it should be regulated. In conclusion, we will only add that we shall be glad to receive relative communications and suggestions; and if gardeners will also inform us of their willingness to become members, we will take steps to have the Society organised so soon as we have a sufficient number of such communications to justify the inference that the Society has the approval of the gardening community.

PLANTING FLOWER GARDENS.

How seldom we see a flower garden which really pleases the eye and satisfies the mind at the same time.

I have often trod with pleasure a beautiful lawn, and regarded with admiration and delight the fine specimens of trees and shrubs growing around me, the soft carpet under my feet. The beautiful variety of cool and quiet-looking green foliage, has produced a feeling of tranquil enjoyment and refreshing pleasure I have seldom experienced in a flower garden.

Let me ask what is a flower garden such as is generally seen? Drive or walk to the nearest nobleman's seat in your neighbourhood, and what do you find? a number of formal beds, each filled with plants of the same colour, producing, if well arranged, a brilliant effect, and the gardener who shows you the place tells you how many thousands of *Calceolarias*, *Geraniums*, &c., he plants per year.

I cannot tell what effect this produces on others, but after the first sensation of pleasure, my eye tires of the bright colours, my mind wearies of the sameness, and I begin to speculate on the cost and trouble incurred in propagating and growing so many tender plants which will so soon be dug up and sent to the rubbish-heap. I should no more think of looking long at such a garden than I should continue to gaze through a kaleidoscope without giving a single turn to the instrument.

Perhaps, in the same garden you see a long, broad bed planted in what is called "the ribbon fashion." Here, at first sight, there appears more variety; there is not the same mass of oppressively bright colour to fatigue the eye; you are astonished, delighted at first, but after walking a few yards feel that there is really no variety, it is a beautiful carpet, nothing more—one square of the pattern is enough.

Perhaps, in spring you pay the gardener of some rich neighbour a visit, and you find the beds filled with expensive bulbs, which have to be purchased each season, and are considered valueless after their beauty is passed. Does it not strike you as savouring of ostentation this waste of beauty? Would not a few clumps of beautiful *Hyalinths* give you more pleasure than this evidence of wealth and extravagance?

"What would you have?" says my friend. "Are we to go back to the old mixed borders, where you see a plant in bloom in the midst of a bare space of earth well hoed and raked to keep down weeds, and surrounded at equal distances by other plants, some in bloom, some just appearing above the ground, and some the beauty of which has long since passed away? Is that your idea of beauty?"

"Well, I cannot say that is quite my *beau idéal* of what a flower garden should be; but I should much prefer it to one filled with masses of bedding plants. There would be a chance of meeting a long-lost favourite, which would recall scenes and faces long since passed away; plants which grew luxuriantly in the home of my childhood, or in the garden of my friend. I

might meet a little plant once gathered on a romantic spot visited for the first time in company with those from whom I have long been separated by distance or death, and though the little plant may give rise to recollections at once sad and pleasing, it would be to me 'a sadness not unpleasing.'"

But are these kinds of gardens the only ones? Oh! dear, no. There are polychrome gardens, such beautiful gardens, little beds of flowers divided by walks formed of broken bottles, broken spar, broken bricks, broken tiles, &c.; walks never intended to be walked upon, such beauties! Ah! well, I am not cockney enough to admire them.

Now, I will tell you what does come up to my idea of what a garden should be. I would have a garden like that at Belvoir Castle, in the spring, or, indeed, at any time of the year, but particularly in early spring. There all the ground is covered by plants which touch without growing into each other; there the plants are all in bloom, or coming into bloom; there are masses without sameness as in nature, where as your path winds amongst the trees you come upon a mass of Wood Anemone, or blue *Hyalinth*. You have variety and effect combined, yet without extravagance—lovely little plants, rarely met with, peeping here and there amongst their showy sisters. I shall never forget the effect produced by *Hyalinths* of different colours growing through a mass of *Arabis caucasica*.

But, pray, ye Editors, send some one capable of describing a garden to Belvoir in the spring, and let your readers know how to manage a garden so as to be always in full beauty, so that a place can be found for every favourite, old and new; a garden which does not require an acre of glass to furnish bedding plants by the thousand, or the purse of a duke to keep it up, but is equally adapted for a princely place like Belvoir, or the modest garden of the curate.

I have not the gift of description, and despair of conveying any adequate idea of the effects produced by Mr. Ingram, with materials within the reach of any person of moderate means. If Mr. Ingram would find time to tell others how to manage a garden as he manages the one under his care, he would be considered a public benefactor.—J. R. PEARSON, *Chilwell*.

ORCHARD-HOUSE FRUIT.

A BRAVE and faithful knight is "R., of S."—not more chivalrous was he of La Mancha when prepared to do battle for the charming Dulcinea; for will he suffer one word of detraction to be uttered against the peerless Orchardina? Do not her eyes shoot out such coruscations, that one is repaid all the outlay to sit and smoke one's cigar beneath her boughs as the house sends out its brilliancy of colour? Is there a bloom on any cheek so lovely as hers? And then when once—coy maiden that she is—she rewards you with a taste of her sweetness, oh! who dare say that there are any lips as sweet as hers? And will he not—nay, does he not—with vizor down (for I remember how he unseated some poor wight who would not allow him his incognito), and sledge-hammer uplifted (for he disdains a lighter weapon), advance to the charge against all who cannot see with his eyes or taste with his palate?

Here am I, a poor halting serving-man, for I dare not even call myself a knight, suffering from grievous bodily hurt inflicted by this trusty champion, because I ventured to fire off a little popgun, and to hint a slight expression of doubt as to the superexcellent character of the fair damsel whom he delights to honour. Alas! I have oftentimes been compelled to bite the dust; and every one who is not contented to go on in a quiet jog-trot way, and who will occasionally utter his own opinions without tacitly submitting to be guided by others, must lay this to his account. But I generally try to shake off the dust, and, if I have a little breath left, to try and say a word to show that I am not "kilt outright."

I think perhaps I ought to have used one word of limitation—namely, most practical men "whom I have met," and with that limitation I still hold to my former statement; and however glad to find that there are some whose acquaintance I have not the honour of having think otherwise and have experienced success, although I quite agree with Mr. Keane that "Duckwing's" success is a very qualified one, I must still hold that they are exceptions, unless, indeed, there be some circumstances not known which would alter the case.

I happened to meet the other day at Kensington a "practical man," (and I think my acquaintance with such is not of a

limited character), and who knows as much about fruit (I will not say as "R., of S.," for I stand in bodily fear of him), as any one, I believe, in the three kingdoms, always excepting "T. R.," and his word to me was, "You are quite right;" and then we had a little talk as to the native habitat of the Peach, and the scorching baking weather it has to endure when it is ripening, and how impossible it seemed to be to obtain in an orchard-house such a temperature. But whatever may be the theory of the matter, I never yet saw an orchard-house *pur et simple*—i. e., with the trees in pots without heat, and I have seen a good many, where the fruit was worth a "dump." I only have been unfortunate, but such is the fact; and I can only say that if I had it in my power to erect one 40 feet long to-morrow, I would prefer to have a house half the size and heat it, so as to get a few really good and palatable fruit. But all these are assertions *pro* and *con.*, and I think it would be very desirable to have something decisive on the point.

I am not a fruit-grower, nor do I pretend to know much about the subject; and so perhaps "R., of S.," will say, "*Ne sutor ultra crepidam*," and let me stick to my last. I have, however, an interest in the matter, and would willingly see something more than mere assertions. To gain this end I would propose that a prize be offered for the best six Peaches and six Nectarines; and that size be not considered a material point, but the merits to be entirely in the matter of flavour; that "R., of S.," send his very best, and let them be put into competition with the same numbers of fruit grown in a Peach-house; and that five members of the Fruit Committee be requested to adjudicate at some period, if possible, when the fruit can be procured from both sources. If those who are interested in the matter think this is a proper way of deciding, I shall be very glad to contribute my quota towards making up the amount of the prize.

Mr. Keane has so well put the matter in last week's JOURNAL OF HORTICULTURE, that I do not think it necessary to add more than this—that had the advocates of orchard-houses been content with moderate assertions we might well have borne with them; but it is the extravagance of their statements that has made practical men—I again use the term, though "R., of S.," says "*soi disant* practical men"—so strong in their statements.—D., Deal.

FRUIT-GROWING—ORCHARDS OR ORCHARD HOUSES?

BRING one of the parties of whom the advocates of orchard-houses have made particular mention as being opposed to their views, I should not have again entered on the subject had I not found that some of my views were imperfectly understood; while the courtesy of Mr. Pearson and the gentlemanly tone of his letter alike call for a reply. Although we may still differ in opinion on the subject of fruit-growing, the manner in which Mr. Pearson has put forth his views disarms opposition of everything personal or hostile; and although I fear I cannot promise myself the pleasure of partaking of his hospitality at the time his orchard-house fruit is ripe, nevertheless I am willing to believe it is good. But supposing I admit that orchard-house fruit often is good, and I have no doubt that it is, can any impartial judge say that better fruit has been grown in pots than has been grown in the ordinary way?

My argument hitherto has been that the system is very "expensive and uncertain," not that fruit cannot be so grown; for, as I said in my former letter, I believe that good Wheat and Barley could be grown in pots as well as Pears and Peaches. But is it expedient to do so when other and better ways exist, whereby corn and fruits can be had in greater abundance and at infinitely less cost?

Mr. Pearson's letter, however, calls for further remarks bearing on the subject of trees in pots; and although I have no doubt but the very able writer in THE JOURNAL OF HORTICULTURE, "D.," of Deal, will reply to those who have found so much fault with him and the worthy gardener at Winchester, I will explain a few of the reasons which have led me to take the view I now do on the subject of growing fruit trees in pots.

I believe I have, in a former article in this periodical, stated that my first acquaintance with Peach trees in pots was made upwards of thirty years ago. A gentleman, extremely fond of gardening pursuits, and one of the first to introduce the curvilinear iron-barred hothouse into general use, took a fancy to try Peach trees in pots, and being ably seconded by his energetic gardener, they produced and ripened their fruit in exactly the

same manner as they ripen now—sometimes plentifully and moderately good, and sometimes a failure would occur. I am unable to say how many years this had been done before the time I speak of, but it was not new by any means in 1832. This was, however, the first successful attempt that I had seen at growing fruit trees in pots, and ripening the produce.

Some few years after that, an intimate friend of mine came as gardener to a gentleman fond of such novelties, and, amongst other features, there was a glass house set apart for a certain purpose in August; and, to make the most of that house during the early summer months, Peach and Nectarine trees in pots were introduced, and crops of fruit obtained in greater or less abundance, as the season and other circumstances determined. These trees, be it remembered, were all in pots, and were of different shapes and sizes; some of them were trained flat to fix against the back wall as dwarfs, and others as riders or standards at the same place, while some were simply kept in bush-fashion to occupy the floor or body of the house. Here, then, more than twenty-five years ago, was an "orchard-house" in the sense in which that term is now applied; but at that time a less ambiguous name was given to it.

Continuing the narrative, I may say that when the time came for removing these trees out of doors, which for other reasons it was necessary to do immediately after the fruit was gathered, they were placed in a sheltered but sunny corner, and the pots were carefully wrapped round with hay or straw bands somewhat after the fashion of the foreign liqueur spirit-bottles. This wrapping-up prevented the sun from heating the pots and injuring the roots, and the pots were sometimes so wrapped round before taking them out of the house, as it was found that plunging them always encouraged rooting-through, and was hurtful when the trees had to be removed.

Having had an opportunity of seeing these trees almost weekly, and sometimes oftener than that for two or three years, I could speak as to the result; I had, however, lost sight of them since 1841, when I accidentally met my old friend last summer, under whose care the trees in pots had continued some ten years or more, ending, I think, in 1847. When the subject of the trees in pots was mentioned, "Ah," he said, "they were a great deal of trouble to me; they were the worst things I had to manage, but I often had fair crops, considering the trees were cramped up in pots." "But," I asked, "how did the produce bear comparison with that of an ordinary Peach-house?" My friend shook his head, and replied that he would much rather manage four Peach-houses having the trees planted and trained in the usual way, than the one with the potted trees in it; and the produce of the latter in the best season he ever had fell far short of what ordinary-trained trees ought to have borne in the same sized houses, while in general the crop, taking quantity and quality together, was less than one-fourth what a good Peach-house would have been.

This is the practical experience of one who had tried the matter fairly for a number of years before the high-sounding title of "orchard-house" was bestowed on structures intended for this class of horticultural produce. I should much like my friend to have given to the world his views on the subject, but the above are the main particulars. It thus appears that Peach trees in pots are not by any means a recent introduction, while the plan of growing such trees in bush-fashion under glass, but planted in the ground, is much older still. The first Peach-house I ever remember having anything to do with in this way was some thirty-five years ago, and the trees were then old ones; they were much less manageable in every point of view than trained trees, and the fruit were no better.

I believe that I related much of the above in a former discussion on the merits of the orchard-house system of growing fruit trees in pots; I also mentioned having at some time of my life had a few trees in pots myself. The last of these, however, was some fifteen years ago, and finding they did not produce anything like the quantity of good useful fruit that could be had by planting them out, I adopted the latter plan. I have, however, not been an indifferent spectator of what has been going on in that way; but like our able and accomplished writer "D.," the usual tale in July or August when the fruit ought to have been ripening was that some awkward apology had to be made for its "falling-off" some time before; the trees had bloomed beautifully, and set well, and all went on well until "somehow or other the fruit took to falling-off, and nearly all are gone." Such is the story one often hears, and I ask Messrs. Rivers and Pearson if they have not often received similar complaints?

One of the most fortunate growers of Peaches in pots candidly told me that his success entirely depended on his allowing his trees every year to root into the ground, which roots he partly cut back the following winter, thereby following out a system of annual "root-pruning." But I ask, Is this growing the fruit in pots? I am willing to believe that Mr. Rivers and Mr. Pearson each grow some good fruit on trees in pots, and I am glad the latter intends to submit some of his fruit to the test of a public show. The complimentary approval of individuals who may be kindly treated by an hospitable host ought not to be taken at more than its worth; it is always much more pleasing to speak favourably than otherwise, and few would act the ungracious part of finding fault with what was kindly placed before them. But even assuming it to be proved (which, by-the-by, has not been yet done) that a fruit grown in a pot is as good as one grown against an open wall, it is only like proving that a silver spade is as good as a steel one; for the costliness of the one mode of growing fruit as compared with the other is about on a par with the relative price of the two tools. The advocates of the silver spade may call Mr. Weaver and myself prejudiced, antiquated, and so forth, because we cannot see the merits of the silver tool, but that does not prove that the silver tool is best. This simile I will, however, further explain, so as to place the relative trouble of attending to plants in pots, as compared with those planted out, in a true light.

On the terraces at Linton we have been in the habit of placing groups of plants for display during the summer season. These plants are all in pots, and consist mostly of Scarlet and other Geraniums, Lobelias, Fuchsias, and such like, to the number of about a thousand, and they are all in pots. Now, though we have a great many thousands of the same kinds of plants planted out in the beds, the attention those in pots on the terrace require during the summer months, in watering and so forth, very far exceeds all that is given to the others; for although I did not record how often the plants in pots were watered, it could not be less than eighty or one hundred times from the early part of May to the end of October. Now, plants of the same kind planted in beds had water only once—viz., at the time of planting.

This is one example of the difference in trouble between plants in pots, and those in the ground, and it may very appropriately be applied to fruit-growing. The simile will bear itself out pretty well, but those who dislike such a comparison I will meet on their own ground, and give another example.

This time we will take Pears, which I see Mr. Pearson does not patronise, but Mr. Rivers does. Well, last summer I went to see some trees in pots that belonged to a gentleman who is ardently fond of gardening, and which had been received some time before from a famed establishment for such things. On Plums, Peaches, and Pears, there was, however, very little fruit; but one Pear tree, a Marie Louise, had three fruit upon it, and the gentleman seemed in high glee at his success. Some time afterwards he sent me word that they had all three ripened. This was about the time that I had some of the same kind ripe also, and I sent him half a dozen specimens to compare them with his own, and he candidly sent me word that mine were the better flavoured. Now, the three fruit the gentleman produced on his potted tree cost him long and close attention in watering and the like, and this was the most successful tree in about forty, taking all kinds together, while those I sent him were taken indiscriminately from a batch of thirty or forty bushels of the same kind which had been grown on open standard trees in a grass orchard, and the gathering of the fruit when it was ready was all the attention the trees had received the whole year. Now, this case might have many parallels, but I merely place it before the general reader as bearing on Pear-growing. I may, however, mention another circumstance connected with this Pear, which may not be generally known. The trees on which those in question were grown, were ordinary standard trees, middle-aged, and which only received a pruning or thinning of the branches once in five or six years, and in some seasons they have been more prolific than last year. Now, we have the same kind of fruit on a wall with an east aspect, and the Pears become much larger, but bear no comparison with the fruit from the open standard in respect to flavour. The latter have a more russetty appearance, and attain a nice size for table. The above is a good example how necessary plenty of air is to perfect our hardy fruits, as other Pears as well as this one are better on the open standard than on the wall, and I can hardly conceive how any fruit ripening under glass can be as good as the same kind is when ripened in the open air. Observe, I say ripened,

I do not mean starved into a premature perfection, or rather imperfection. Strawberries forced are inferior to the same ripened in the open air, and the same may be said of Peaches and Nectarines generally, and to improve the flavour of the latter they are invariably treated to the greatest circulation of air the house will admit of. Such, however, is the general way of managing those in Peach-houses. In orchard-houses the treatment is much the same.

Having carried the above remarks to a greater length than I intended, I have only space to reply to your correspondent, "R., of S.," who says, "that the flavour of fruit is entirely under the control of the gardener." I will, however, ask him the simplest of all questions, one possibly beneath his contempt. How are Gooseberries to be grown near London so as to be of as good flavour as those produced in Lancashire? I am not too old to learn, and would like to know much more about the flavour of fruit than I now do, and certainly would consider myself a very clever man if I had it under my own control. I would waive all opposition to orchard-houses, and give "R., of S.," the credit of being an oracle, if he would only put me in possession of this secret. With regard to the article of "Duck-wing," it is needless to say much, since the drift of his argument is on the side of "D." Mr. Weaver, and myself, for he acknowledges failing with four out of the six kinds of fruits he attempted to grow; but as he candidly acknowledges knowing only the orchard-house cultivation, and thinks himself successful by managing two out of the six fruits he commenced with, it would be ungracious to deny him the amount of credit he deserves. At the same time I would just say, that before he again decides on the merits of contending objects, he ought to do something more than merely make himself acquainted with one of them only. The readers of THE JOURNAL OF HORTICULTURE most likely have heard plenty of this orchard-house dispute, and certainly any article on this subject loses much of its value if the writer does not give his own name and address.—J. ROBSON.

ORCHARD-HOUSE TREES.

"I do not like thee, potted tree,
The reason why I cannot see—
But I don't like thee, potted tree.
I like thee dearly, Prejudice,
Thy narrow path is very nice—
I love thee dearly, Prejudice!"

As Mr. Keane dabbles a little in poetry, I am tempted to give him the above paraphrase from Wordsworth, which I have no doubt he will think apposite and interesting.

But to go to the matter of fact of orchard-houses. I could not help feeling some little surprise on reading Mr. Keane's last article on the subject, for I cannot see why he should have taken the trouble to write several paragraphs without giving us a particle of information. He has, it is true, given us three quotations, one poetical, one doggerel, and one prose—all most remarkable for their bearing on the subject; but why does Mr. Keane, who is one of your constant contributors, and whom we, your readers, think bound to give us sound information, why should he employ that unsatisfactory phrase, "we are told?" He may just as well insert in his weekly calendar, "We are told that at Brentford Melons are grown in mud in the open air." Would not your readers say, Why not go and see? and so I say, Why not go and see? Sawbridgeworth is but one hour's ride, and there he may see Apricots, Plums, Pears, Cherries, Peaches, and Nectarines, all growing in a climate apparently well adapted to them.

"We are told" may do very well for a reporter to a newspaper, but no writer on gardening should employ it, unless it relates to something extraordinary—such as, for instance, "We are told that in the moon Melons are grown in boiling water, and are always remarkable for their tender flesh." Well, we should let that pass, because we now know that a journey to the moon, if we may depend on Mr. Glaisher's experience, would be a cooler to a lover of tender-fleshed Melons.

With regard to perseverance being based on well-organised plans, referred to by Mr. Keane, the culture of trees in pots is most firmly based; for who that has travelled with their eyes, and, above all, their minds open—not walking in the narrow, "nice" path of English prejudice—could avoid deducing from Orange-tree culture in tubs, the trees kept in vigorous health by annual top-dressings for hundreds of years; for the Orange tree at Versailles is four hundred years old, and many others

upwards of two hundred; I say, who, with any activity of mind, would not have at once asked himself—If one species of fruit tree can be thus cultivated with success, why should not all kinds?

Again: besides Orange trees, the observing traveller may see in all parts of the Continent, except the extreme south, Pomegranates, Loquats, Bays, Laurustinuses, Myrtles, and many others, all of great age, but still full of health and vigour, and all growing in tubs, and kept in luxuriant growth by surface-dressings.

The truth is, there is no limit to this mode of culture. Potted fruit trees seem to increase in health as they increase in years. My Apricot trees in pots, some of them now twelve years old, are more robust and fruitful than ever; and in the year 1883, when they are being viewed, the young gardener of that day will say, "Is it possible that this mode of culture was objected to by men of a decent calibre of intellect?" and they will surely believe that Jasper Standstill, M.P. for Dulltown, had numerous supporters among the gardeners of 1863.

I must, however, candidly confess that I fully excuse Messrs. Keane & Co. for their peculiar mode of thinking. I have imagined myself to be a thoroughbred and competent gardener, and I have, in imagination, placed myself in what is called a first-class place; walls covered with well-trained trees; every shoot in its place, and all under my sole direction. Well, in the course of time, the system seeming quite perfect, my mind becomes so thoroughly imbued that I listen to a plan of growing Peach trees as bushes, pyramids, and half-standards, without training them flat to a wall or a trellis, as some kind of romance (like Dana's adventures in Marquessa, truth-like, but not true), for I find it impossible to tolerate the idea of growing Peaches without crucifying the trees against walls. Such I believe to be the mode of thinking of many good and clever men: their walls have enclosed their gardens and their minds, so that their gardens have been to them a sort of happy valley, in which, if Johnson could have known them, he would have placed Rasselas.

I hope I have shown that there is really no credit due to the originator of orchard-houses. The idea is hundreds of years old, and he must have been very dull not to have caught it up on the continent. The only wonder is, that such men as Mr. Keane, Mr. Robson, and many others were not in the field before him. It seems almost incredible that they should have seen trees cultivated in pots and tubs by surface-dressings for years and years, and yet not have promptly extended the system to all kinds of fruit trees.

The author of the "Orchard-House," therefore, may think himself a fortunate man to have escaped such rivalry; for who knows, the book instead of now being on the eve of its eleventh edition (eleventh thousand), would, perhaps, after the first have been forgotten?

Mr. Keane can, perhaps, inform us if any pamphlets were published on Polmaise heating and Vine-coiling, and what success they had. I only seem to remember those matters as the little charlatanism of the day. I have, in common with many others, many thanks to render to Mr. Keane for his "Out-door Gardening," a capital book which is always on my table, and without which I should not know when to sow Cabbages or even Spinach.

I observe that Mr. Keane has used a famous political phrase—*coup d'état*. This is, undoubtedly, a clerical error; he intended to have written *coup d'éclat*, which is much more apposite. Following Mr. Keane's example I must conclude with a doggerel rhyme—

"When'er you write on knife or spade,
Confiné yourself unto your trade."

—R., of S.

BLOWER DROPPINGS.

SOME time ago I read a question in this Journal about the qualities of what goes here by the above name. Blower droppings are the refuse of Cotton seeds and scales of Cotton seeds, along with other vegetable substances, which come from the Cotton in its first process of manufacture. I have used much of it, and know many more in this neighbourhood who have used it rather extensively.

One friend says, that mixed with a little soil and a good layer of it put under the mixture, it will grow better Early Radishes than anything else. Another friend, who is no mean gardener, says it is equal to cocoa-nut fibre refuse, and he has tried both.

I have used it in a mixture of soil, manure, and sand, in

about equal quantities, and I find it very good for Stocks, Asters, and Calceolarias. Used half-and-half with manure, it makes a first-rate compost for growing Celery.

It is very plentiful about here at present, on account of there being so much Surat Cotton used at such mills as are working.

It heats well, but does not retain its heat a long time.

I have a farmer friend, who says that, mixed with manure, it will produce twice as much grass as manure will by itself.

It can be had cheap enough, and I must say it is very useful in any garden, especially where the soil is short of vegetable matter.—JOHN HAGUE, *Gardener, Gridby Lodge, Ashton-under-Lyne.*

THE BROWN PEACH APHIS.

WERE I inclined to make an assertion without having made use of my eyes to gain experience, as too many writers are apt to do, I should say this aphis must be a recent importation, but it has, very probably, been with us a long time. Of late years the cultivation of Peach trees under glass has increased to an enormous extent, and this species of aphis seems to have increased in proportion.

It differs from the Peach aphis of the various works on gardening, for that is described as being green; and another difference exists—the green aphis attacks the young shoots in spring and summer only, but our brown enemy is often found on the bare young shoots of the Peach tree in November and December, and this was why the Gishurst compound was recommended as a winter-dressing. It is certainly a most effectual remedy, and kills the aphides and their eggs; but owing either to its being made of different degrees of strength, or from some other cause, it has undoubtedly been occasionally productive of mischief in weakening the blossom-buds and causing them to drop off: much caution should, therefore, be used in applying it. In 1858 and 1859, 6 ozs. to the gallon of soft water were infused, and the mixture was applied freely. Its effect as an aphis-killer was excellent, for not an aphis or an egg was left, and the trees were clean all through the ensuing summer; but in December, 1860, and again in the same month in 1861, with an infusion of the same strength, the trees remained perfectly clean, but a large number of blossom-buds dropped off: whether this was owing to any inequality in the strength of the compound or from what other cause I have never yet been able to understand. It shows, however, that caution should be used in applying this excellent aphis-killer.

The month of December, when the buds are quite dormant, is the most advisable season for washing Peach trees under glass with it, and 4 ozs. to the gallon of water the proper strength. Last December, 1862, my trees were so clean and healthy that I did not dress them as usual with the compound. Their blossoms this spring have been strong and beautiful, and have set well, but within the last fortnight the brown aphis has made its appearance on many trees. Its increase, as stated by Mr. Fish, is almost magical; for in one night a shoot on which none could be discovered the day previous will be a brown mass of aphides.

I inquired to-day of the young man who has charge of my large orchard-house, 100 feet by 24, in which there are some hundreds of Peach trees, if he could keep the brown aphis down without fumigation. He said, "Yes, by looking over the trees rigidly." The following is the remedy applied—it is most satisfactory, and has not the least injurious effect either on the young leaves or young fruit—4 ozs. of quassia chips boiled ten minutes in a gallon of soft water, and while cooling dissolve in it 4 ozs. of soft soap; the mixture applied with a small painter's brush. So efficacious was this found last year on trees out of doors infested with aphides, particularly Plums and Cherries, that this season I have ordered 56 lbs. of quassia chips from a wholesale druggist. As Mr. Fish suggests, a few lines on the natural history of this apparently new species of aphis would be of much interest.—T. R.

THE SEASON IN THE LOTHIANS.—What a splendid spring we have had here! Apricots on open wall are as big as pigeon eggs.—D. THOMSON, *Archerfield.*

EARLY POTATOES FROM CORNWALL.—Several parties are now (April 23) busily engaged drawing (digging-up) Potatoes in the neighbourhood of Penzance for the London market, and the crop is said to be above the average.—W. P., *Cambourne.*

FLOWER-BORDER.

PLAN FOR RIBBON-BORDER UNDER A WALL.
32 feet 6 inches.

1, *Perilla nankinensis*, 1 ft. broad.
2, Variegated Mint, $\frac{1}{2}$ ft. broad.

3, *Lobelia speciosa*, $\frac{1}{2}$ ft. broad.
4, White Candytuft, 1 ft.

5, Nothing.
6, Roses.

7, Box-edging.

"MUDDLER'S" questions are—What do we think of the form of the border? what of the planting in unfavourable circumstances? and what improvements can we suggest?

The main features of the curved lines of the border we cannot but approve, as in borders more than ten times your length we have followed something of the same plan for two years. This season we think we shall revert to straight lines instead, for a change, though it does not look so artistic. As far as effect is concerned, there is not much difference in the two systems. The curved lines are, perhaps, the best as you walk along the side of your border, and show more intricacy and contrast of colour in whatever direction you look; but then they do not tell so well when you stand at either end and look along them as straight lines do, even if all is done well, and the heights are properly arranged. If there is a fault in the arrangement of heights, it will be bad enough to look at it from the sides of the walk; but it will be a perfect jumble if looked at from either end. This, however, has nothing to do with the mere ground plan of your proposed lines and two circles in front, with which we are very much pleased, as it shows how many tasteful ways there are of doing the same thing. The sweeps at the ends and the circles in front give an artistic charm to the waved or serpentine lines of colour. There is just one thing which we think would improve your plan, on the system you have adopted, and that is a straight line in front, and a straight line at back, to harmonise with the straight line of your walk and the straight line of the wall. If you had not room otherwise for this, we would make one waved line the less. It would give a completeness to the design, which it at present wants, and more especially if there is any space for path or otherwise between the wall and the triangular waved spaces at the back, marked 5. These straight lines would be the setting for your picture—the frame, so to speak, which would make you independent of trusting for that either to the wall or mere edging at the walk. For instance: there are your curved sweeps, 2, that touch the walk, filled with variegated Mint, and there are triangular pieces between them and the circles, 3, planted with *Lobelia speciosa*, which, except in the curves in front of the Mint, will do admirably; but then just think of a straight line of the *Lobelia* taken all the way, if Box-edging is next the walk, or *Cerastium tomentosum*, if of grass, and you will perceive what a completeness would be given to the setting. Mind, that is only our opinion. Some people might like it better as it is.

Now, we are well aware of your difficulties in making a very showy border on a north-east aspect; but if you have tried the *Perilla* and *Lobelia*, and find them answer, we have no doubt that *Calceolarias* and *Scarlet Geraniums* in pots would flourish tolerably. We must say, however, that we like the plan of your border better than the proposed planting. Without taking objection to the proposed colours, there is but little attempt made to regulate them as to their heights. Last year, in some of the fine borders and clumps about London, the outsides were the highest, and the inside or centre rows were the lowest; and some good friends, and ladies amongst the number, have told us how nice they looked, and that they would imitate them next year.

Our own opinion is, that in these cases which were thought of so favourably, the planters had been disappointed, and that they were rather vexed about what other people in search after novelty looked upon as an attraction. Now, if such be your views, we can see little wrong in your planting. But if you have any idea that in a border in front of a wall the rows, to be seen, should have a suitable relation to each other in height, then we do not see how your proposed planting is to be defended, unless you make everything of much the same height by layering, pegging, &c. One incongruity we may likewise mention, and that is the perpetual character of the *Roses* in No. 6, whilst all else would be only of temporary duration. Looking on the two circles, No. 6, as main features, and presuming that they are to be filled with low-growing China *Roses*, they will not only look well, but your surrounding them with the belt, 2, of variegated Mint, will give a completeness to them, and remove the objection to the centre bed of "*S. E. L.*" the other week. Then, as already stated, the triangular waved spaces, 3, of *Lobelia speciosa*, are all right enough, and so would be your waved line, 1, of *Perilla* behind all these; and we should not greatly find fault with the waved line, 2, variegated Mint behind the *Perilla*, because we could prune down the *Perilla*, and let the back row of 2, Mint, grow to overtop a little the *Perilla*. But how are we to manage the back row of 3, of *Lobelia* again behind these, which naturally will not rise above a few inches? and then, again, the broad line of white Candytuft will be a blaze while it lasts, but it will seed about July or August, and leave nothing to look at. You think it will be a foot in height, but then to give it its due, 2 and 1, the Mint and the *Perilla* should not be higher than the *Lobelia*, and thus much of the interest of the sprigs of the *Perilla* would be gone. Besides, with the exception of, we may suppose, crimson *Roses* in No. 6, the whole of your border will consist of cold colours, blue, purple, white, and white and green.

Now, on that principle we would allow 3, 2, 1, 2, counting from the walk, to remain as they are, only the back, 2, to grow taller to overtop the *Perilla*, and then the 3 behind we would fill with dwarf blue *Ageratums*, and 4 with double *Feverfew*; and 5, unplanted, we would fill with strong crimson *Roses*, or simply with masses of *Lobelia cardinalis*.

But, again, were we to please ourselves more, we would do 6, 3, 2, 1, as proposed, and keep down the 1, *Perilla*, make the second 2 behind it not Mint but yellow *Calceolarias*, or yellow *Chryseis* or *Eschscholtzia*; 3, behind it, *Ageratum*, dwarf, or *Delphinium formosum*, planted thickly, and half of the plants cut down to a few inches in height; 4, white double *Feverfew* done the same way, and allowed to grow to the full height; and 5, and row all along, *Salvia fulgens*. This would give you gradation in height as well as change of colour. If such things as *Catchfly* are used, it would be well to sow in patches now, and again in June, and thus the bloom might continue to the end of the season. *Lobelia cardinalis*, well dunged, would also be brilliant for 5, or even a row in addition all the way at the back. All such borders should be changed every year.—R. F.

GOMPHOLOBIUM BARBIGERUM.

(BEARDED-KEELED GOMPHOLOBIUM.)

Class, Diadelphia. Order, Decandria. Nat. Ord., Leguminosæ.

GENERIC CHARACTER.—Calyx, five-parted, nearly equal. Carina of two concrete petals. Vexillum, broad, spreading. Stigma, simple. Legume, many-seeded, nearly spherical, and very blunt.—(*Mag. Bot.*, vol. xii., t. 19.)

SPECIFIC CHARACTER.—Plant, an evergreen shrub. Stem, erect. Branches, angular. Leaves, alternate, nearly sessile, trifoliate; leaflets linear, rather acute. Pedicels, furnished with minute bracteoles. Flowers, about 2½ inch in length, handsome, golden yellow. Keel, bearded along the suture, Vexillum, large, longer than the calyx and keel. Pods glabrous.

It is recorded in botanical catalogues that *Gompholobium barbigerrum* was introduced to this country in 1824; but it is questionable whether, if this be correct, it was not again soon lost, as we have no account of it until about three years ago. But however it may have been with respect to its first introduction, it has certainly now found its way into many collections. It is a native of New Holland.

Under cultivation nothing beyond the treatment bestowed upon greenhouse plants generally is required. It is a robust grower, particularly when compared with *G. polymorphum*, and some others. Plants in very fine condition were exhibited in London in 1847, by Messrs. Lucombe & Pince, of Exeter, who are said to have been the first to introduce the species to this country. A specimen grown by them had become a large bush, and was profusely decorated with its fine yellow blossoms. It is easily increased by cuttings.

Mrs. Lawrence's extensive and famous collection of plants, at Ealing Park, furnished in the spring of 1850 the specimen from which our engraving was prepared.

The soil requisite for it is a mixture of sandy loam and peat, and the plant must stand in a light airy greenhouse, like other New Holland plants, and receive a liberal supply of water during summer, but in winter must be watered with care.

The generic name is derived from *gomphos* a club, and *lobos* a pod, in reference to the shape of the seed-pods.—(*Paxton's Magazine*.)

MANAGEMENT OF SPRING BULBS AFTER FLOWERING.

As most amateur gardeners desire to make the best use of their flowering bulbs in future years, may I ask you how they should be treated after removal from the house to the garden? It is a story you have often told, so you may be loth to burden your pages with such elementary work.

The plan I have always adopted, and which you, I believe, have advocated, is, after the beauty of the flowers is over, to cut off the flower-stalks, and carefully to plant the bulbs in some spare ground; then, when the foliage is completely dead, to take them up and to store them in bran or sand, that in the autumn they may be put into the border. A friend, who is a very successful

florist, told me that I was wrong in thus placing them where their growth might be prolonged; that the roots spent all their second growth, and would rot away; and that after their flowering was over they should be gradually dried-off, and after a while the earth shaken from them. He, moreover, gave as a reason that the future blossom was forming while the bulb was at rest.

Now, I presume the physiology is, that so long as the leaves remain green and vigorous the roots are in action, and storing up materials for future growth, that the longer the leaves continue in vigour the better is the promise for the future. There can be no doubt that the finest blooms of the larger *Narcissus* are to be gathered from those roots that have not been moved for years; the bloom is larger and more vigorous, though later than when the roots have been potted. The same rule obtains with the *Crocus*, with *Gladiolus*, and the common *Narcissus*; whether it is applicable to *Hyacinths* I do not know, as they were removed to make way for other plants.

Acting on your suggestion, last autumn I put some of my Hyacinths into a heap of mould, and when the bloom was quite large I carefully lifted them into pots, using one-third coco-nut fibre refuse and two-thirds maiden loam; they did not flag at all by the removal. This spring having been so exceptionally warm and free of frost has rendered this more applicable than in ordinary seasons. The blooms of these have much surpassed those more carefully managed in pots, and covered with ashes before they were brought into the house.—B. J. S.

GEOMETRY APPLICABLE TO GARDENING.

(Continued from page 295.)

THE line also receives various denominations, according to its position and properties.

A perpendicular is a right line, that is made or expressed by the fall of a plumb, or by the elevation at right angles of any line upon the middle or end of another, as is A, B, and C.

A line horizontal, is a line of an equal poise, which inclines equally on the one part and the other, as D E. In gardening it is generally understood to be the basis or bottom of a terrace, slope, &c., though it is properly any level line, and may as well signify the top of a terrace, or any other plane, or dead level.

An oblique line is neither horizontal nor perpendicular, but sloping as G H , and may be more or less steep, as seen in the slopes of ramparts and terrace walks. This line is called the hypotenuse, when we speak of artificial triangles. Every slope from rampart or terrace is formed by a triangle, though the horizontal line and the perpendicular be unseen. G H is the hypotenuse or slope line; B , horizontal; A , perpendicular.

Lines parallel are those that are of equal distance from each other, which, though they are extended never so far, are neither nearer nor farther off from each other, as are the lines F.

These lines are all demonstrated in the accompanying figure taken from a celebrated author to show one form (and we think

an unfortunate one), of a terrace. *A*, is the unseen though not less real perpendicular line. *G B*, is the natural or made horizontal line, on a plane with the horizon. *B B*, are parallel lines. *B I* may be supposed to be a level horizontal line raised artificially as the surface of a terrace. *G H* is a sloping hypotenuse line in the form of a bank on one side of that terrace; *C*, an architectural perpendicular line bounding the other side of the terrace; *E*, a continuation of the horizontal line *B*, either natural or made artificially to give relief to the perpendicular *C*; *D*, a natural slope of the ground forming the irregular hypotenuse line to another triangle.

We have said that this figure, though illustrating these lines, is as to the position of a terrace unfortunate. Terraces are most commanding when they join a mansion, and when the ground slopes from them instead of down to them. In such cases earth for the purpose can easily be obtained, and the whole of the excavations for foundations and cellarage, even if there are no offices below ground, can be rendered effectual for this purpose instead of being carted away.

A terrace walk will also be very effective when made horizontal along the sloped line of a hill, with a steep ramp, as *G H*, in front of it; but we should think it rather strange if for forming it we were to dig a ditch, as at *E*, behind it, out of the rising ground *D*. For what these lines represent we can see no place whence the earth to form the terrace is to come from, except from the small space above *E*, as represented by the dotted lines *C D*. Suppose that a terrace is made in such a position, there is nothing for it but carting from a distance and using the foundations and cellarage of the mansion for such a purpose. A terrace should never be commenced without calculating the yards of solid hard-rammed soil that will be required, and whence that soil can be easily obtained. If the soil at any one part should be raised from a yard to two or more yards in height, it matters little what the bottom layers may be—brickbats, rubbish, clay, anything provided it be well rammed, and if flower-gardening is intended, there be from 18 to 24 inches of good soil on the surface. If grass only is wanted, then the half of that will be enough. The layers of soil should never be above 4 inches thick before being well beaten, and the more they are wheeled and carted over, and rolled heavily as the work goes on, the better will the ground stand at the desired level.

Unfortunate as we judge the position of the line *B I* as the top of a terrace, there are many such to be found, and much admired by their possessors and friends; and no doubt they will always yield dry walks at all times and seasons. Two of these have already been noticed in these pages: one of them is between the lawn and the park in front of a palatial residence. Carry the horizontal line *G F* farther back through level lawn to the mansion, and carry the line *E* horizontally almost into the park, and you have one of these terraces. Let *F G*, *G H*, *B I*, stand as they are, but change the upright *C* into a slope like *G H*, and extend *E* to a good wide level as a pleasure ground, and you have an exact resemblance of the other. What they could have been made for, unless for getting rid of foundations and cellarage, we never could make out. Except for securing a dry wide walk, they are every way out of place in the circumstances. Suppose instead that the mansion was built on the sloping ground *D*, and that the upright *C* was a balustrade in front of it, how different would be the effect of *B I* and the slope *G H*. Here, too, we could see whence much earth would come for the formation of the terrace, and that close at hand. If such were the position of the house, then, though the sloping bank *G H* would do well enough, or be made more artistic by a steeper slope, a much better artistic and architectural effect would be produced by doing away with the slope, and having a perpendicular wall as at *C*. On the other hand, if the front of the house extended upwards from the perpendicular *A*, and the perpendicular *C* in front of terrace as now, and the upward sloping park as at *D*, then the horizontal *E* should not be wider than necessary for security, and as little would be done as possible to prevent the eye of a person on the terrace at *A* resting complacently on the park scenery at *D*.

(To be continued.)

SALE OF ORCHIDS.—Another sale of these took place at Mr. Stevens's rooms, King Street, Covent Garden, on Wednesday last, when the total amount realised amounted to nearly £500. The following are some of the prices obtained:—*Ardis Shroderi*, £16 10s.; *Cypripedium Lowii*, £20; *C. villosum*, £6 10s.;

Cymbidium eburneum, £15; *Saccolabium curvifolium*, £12 12s.; *Sobralia superba*, Woolley's variety, £10 10s.; *Cattleya superba* with twenty-two bulbs, £6 6s.; another plant of the same, £5; *Rodriguezia secunda* major, £5 5s.; *Phalenopsis amabilis*, £5 15s.

ORCHARD-HOUSES.

I CANNOT allow the controversy respecting orchard-houses to close without striking one blow in their defence. In 1860 I was advised to build an orchard-house, but I had so great a prejudice against trees in pots that I demurred. In the autumn of that year I went to see Mr. Pearson's houses at Chilwell, near Nottingham, and, although expecting little gratification, I was charmed. The famed gardens of the Hesperides with their golden fruit, which we read of in our youth, and the gorgeous descriptions of the "Arabian Nights," never warmed my imagination half so much as the reality of Mr. Pearson's orchard-house show. My scepticism vanished, and I became a convert at once, and a disciple of Pearson.

My house is 60 by 20 feet; it has no artificial heat, and the climate is, therefore, always pleasant, and one can walk in it without the, to me, disagreeable sensation which artificial heat communicates. My wife, and a labourer who knows nothing of gardening, but who has sense enough to follow Mr. Pearson's directions, are the staff. In the early spring we have a flower garden in the varied bloom of each description of fruit; and the bees we introduce to fertilise the bloom, work and hum away without annoying any of us. We watch the growing fruit with never-failing interest, and the only alloy of our pleasure is the gathering of it; for we can hardly help wishing that in all its beauty it might hang on the tree for ever.

When the summer is not entirely sunless we think the flavour of the fruit superior to that grown out of doors, because unchilled by frost, or too rapid changes of atmosphere, and it escapes the coddled flavour so general with fruit grown by artificial heat.

As regards quantity, the first year we had a fair crop, though many of our trees were small, and some of them maiden plants. Last year, notwithstanding the sunless summer, we had a good show on the trees, many of them bearing three dozen—they were thinned down to that number—fine fruit, and the smaller trees from one to two dozen each.

In size our Peaches were from 7 to 10 inches in circumference, and a Stanwick Nectarine we measured was 8 inches. We exhibited six of our trees full of fine fruit at our Horticultural Show last August, and they surprised and pleased both professional gardeners and amateurs. This year the fruit has set well, and there is every prospect of a good crop.

Into the mercantile part of the question I do not choose to enter; but if any one wishes for an enjoyable spot let him set up an orchard-house, and from the beginning to the end of the year it will afford him a never-failing source of interest.

I say "we," because I speak also for my wife, who is my head gardener, and joins me in all my love and praise of orchard-houses, and in a vote of thanks to Mr. Rivers who first introduced them, and to Mr. Pearson, who has spread the taste for them through the midland counties.—ABRAM BASS, *Moat Bank, Burton-on-Trent*.

SEAWEED AS A MANURE FOR ASPARAGUS, SEA-KALE, AND POTATOES.

AT page 258 of THE JOURNAL OF HORTICULTURE appeared a brief account of the good effects of seaweed as a winter-covering to Sea-kale, and also the query whether a similar application to Asparagus would be attended with equally good results. My own experience in the matter enables me to say that if the soil is dry and porous it may be used *ad libitum* and with none but good results. The finest Asparagus I ever saw, whether as regards size, quantity, or delicacy of flavour, was grown in a soil three-fourths sand, and this resting on a gravelly bottom. The beds had a thick covering of seaweed every winter, and had occasional doses of the drainings of the dung-hill in summer. This with a slight stirring of the surface of the beds in spring after the covering was removed, was all the management they ever had.

I have also used it as a winter-covering for Sea-kale in a way similar to that spoken of by "T. W. B.," only I had the sea-

weed removed from off the crowns of the roots early in March, and old barrels or Sea-kale pots put over them—a plan which I think is superior to that of your correspondent: firstly, because the Sea-kale is much more easily got at; and secondly, because it keeps the Sea-kale nice and clean, neither are the Kale shoots so likely to be broken, as from their crispness they are very apt to be.

In strong soils, however, especially if they are at all retentive of moisture, I should be very doubtful of its suitability as an application to Asparagus. I have never had an opportunity myself of experimenting with it in soils of this kind; but a gentleman, an amateur friend of mine, informs me that he had his Asparagus-beds thickly covered with it one winter, and the result was anything but satisfactory. The beds were very thin the following spring; and upon examining them large numbers of the crowns of the roots were found to be rotted to a perfect jelly. The soil in this case was a deep loam, not wet, but moist rather than otherwise. It is probable that a surface-dressing with seaweed would be more suitable for Asparagus-growing in strong soils, as has been suggested by the Editors. However, as it is only conjecture, perhaps some of the readers of THE JOURNAL OF HORTICULTURE who have had an opportunity of testing its value will favour us with the result.

One thing, however, is pretty certain—namely, that seaweed should always be used as fresh as possible, as there is a positive loss of nutritive matter if it is allowed to remain in a heap and ferment.

In dry soils it is also an excellent manure for Potatoes. I have had first-rate crops of this vegetable by the use of seaweed alone, and where it can be had in plenty, it may be dug into the ground for general crops.—J. DUNN.

THE ROYAL BOTANIC SOCIETY'S THIRD SPRING SHOW.

THIS, the last of the Spring Shows for the season, was held on Saturday the 25th inst.; and the display, as on former occasions, was excellent. The weather, too, so important a consideration in connection with a flower show, was highly favourable; the day having just enough of sun to make shade agreeable, and just enough of breeze to keep the atmosphere from becoming languid. Roses, cut and in pots, together with the miscellaneous collections of flowering and foliage plants, constituted the principal features of attraction; to which Cinerarias, Pelargoniums, and Azaleas lent no unimportant aid.

Roses in pots were in the highest perfection, especially those contributed by Mr. Turner, of Slough, Mr. William Paul, and Messrs. Paul & Son. Those from Mr. Turner were Souvenir de la Malmaison, Madame de Cambacères, Paul Ricaut, Paul Perras, and Chénédolé—all of which, as regards size and abundance of bloom, could not have been surpassed. Mr. W. Paul's collection of six were likewise magnificent, consisting of Madame Boll, Empereur de Maroc, Anna Alexieff, Paul Ricaut, Souvenir d'un Ami, and Charles Lawson, the last particularly fine. The same distinguished cultivator had also a nice collection of ten, among which Beauty of Waltham, Comtesse de Chabillant, Sénateur Vaisse, Victor Verdier, and Lælia caught the eye; but the remainder were almost without exception equally fine.

In Messrs. Paul & Son's collection were fine plants of Madame de St. Joseph and Souvenir de la Reine d'Angleterre; whilst in that of Messrs. Lane and Son, Paul Perras and Paul Ricaut were fine examples of those highly esteemed varieties. Mr. Cross, gardener to Sir F. Goldsmid, Bart., Regent's Park, likewise contributed a collection, in which Souvenir de la Malmaison and Général Jacqueminot, standing side by side, were of striking beauty.

Fine boxes of cut blooms, comprising nearly all the leading varieties, came from Mr. W. Paul, Lane & Son, Messrs. Paul and Son; and Mr. Treen, of Rugby, was likewise an exhibitor.

Collections of foliage and flowering plants came from Messrs. A. Henderson & Co., among whose plants were a large *Dracæna ferrea* and *Jacaranda filicifolia*, remarkable for its elegant fern-like leaves. Also from Messrs. Lee, of Hammersmith; F. & A. Smith; Cross; and from Mr. Smith, gardener to the Duke of Northumberland, at Syon House, who had a magnificent *Maranta zebrina*, an enormous *Latania borbonica*, *Azalea Triumphant* (a splendid pyramid of bloom), *Caladium bicolor* Madeira, also large and fine, and *Acacia grandis*.

Mr. B. S. Williams exhibited two collections, one being of

mixed foliage and flowering plants, the other of foliage plants exclusively. Among the former we noticed a magnificent *Cyanophyllum* and a remarkably fine specimen of *Theophrasta imperialis*. *Gleichenia flabellata*, *Vanda suavis*, with two fine spikes of bloom, and a nice pyramidal plant of *Azalea amœna*, in full bloom, were the most striking of the remainder.

Of Cinerarias there were several excellent exhibitions, the best coming from Mr. Lamb and Mr. Turner. Those from Mr. Smith, of Syon, and Mr. James, of Isleworth, were also very good.

In Pelargoniums, Mr. Wiggins, gardener to W. Beck, Esq., Isleworth, had *Multiflora*, *Beadsman*, *Alma*, *Pline*, *Virginie*, all of which were in good bloom; also, a group of Beck's seedlings, of which *Princess Alice* seemed the finest. Mr. Turner, of Slough, had fine plants of *Clarissa*, *Spotted Gem*, *Phoebe*, *El Dorado*, *Vestal*, and *Pescatore*; and Mr. Cross was likewise a successful exhibitor.

Of Auriculas, the finest were from Mr. Turner, the kinds being Spalding's Metropolitan, Oliver's Lovely Anne, Maggie Lauder, Cheetham's Lancashire Hero, Meteor Flag, and Dickson's Duke of Cambridge. Mr. Turner had also a very interesting collection of sixty pots of the best varieties. In the collection of six sent by the Rev. H. Dombain, which was also excellent, Meteor Flag and Campbell's Pizarro were, perhaps, the finest. Good exhibitions of this flower also came from Mr. Holland and Mr. James, of Isleworth, the latter of whom had also six Alpines.

Pansies in pots were contributed in fine condition by Mr. James, who had also twenty-four cut blooms; whilst Mr. Bragg, of Slough, had a stand of twenty-four, and two stands of thirty-six each, as well as a pretty seedling called *Vesuvius*.

Of miscellaneous objects the most conspicuous was a group of seven magnificent Azaleas from Mr. Turner, of which Barclayana, Holford, and Chelsoni were particularly remarkable. Messrs. Perkins, of Coventry, again exhibited their truly unrivalled *Verbena Lord Leigh*. *Gloxinias*, both of the drooping and erect kinds, came from Messrs. F. & A. Smith; and one hundred blooms of different varieties of *Verbena* from Mr. Treen. Mr. James had fine herbaceous *Calceolarias*; Messrs. Dobson & Sons, Snowflake, a fine white dark-centered *Cineraria*; Mr. Turner, *Bougainvillea speciosa*, flowered in small pots; and Mr. Bull, of Chelsea, a large collection of new and rare plants, among which were a fine specimen of *Pandanus javanicus* variegatus, *Acer Negundo* variegata, with very ornamental white variegations; *Rhododendron Victoria Regina*, with very fine white flowers with yellow spots; a handsome red-veined *Pteris*; *Pogonia discolor*, from Java; and *Serissa fetida* variegata, the small deep green leaves of which were nicely edged with white. Lastly, Messrs. A. Henderson & Co., had *Rhododendron Edgeworthii*, the large white flowers of which perfumed the tent; and several nicely-filled flower-baskets, flower-vases, and pots of potteryware in various designs.

NEED NEW FLOWERS BANISH OLD FLOWERS?

ACCORDING to some writers, it would appear that the modern system of bedding-out and massing bright colours in the flower-borders engrosses the attention of the whole gardening world, and that the old-fashioned method of planting the borders with a heterogeneous mixture of herbaceous plants arranged in picturesque confusion has altogether died out. Those who entertain that opinion should inspect suburban gardens, and they will find numerous small gardens managed on the old-fashioned principle.

The amusing account given by "TOWN-BRED," of his first exploit in the study of old-fashioned garden lore, has brought to light two important facts:—First, That there are intelligent people in the world who are willing that old-fashioned border plants should not entirely die out; and, secondly, that the generality of modern gardeners seem to take very little interest in them.

There are many so-called gardeners who gird themselves with a blue apron, which gives them the appearance of knowing something about gardening, and who discourse eloquently on "Gereenums," "Ellytropes," "Verbinias," &c., but who are blissfully oblivious of such border plants as *Geums*, *Potentillas*, *Saxifrages*, *Veronicas*, and the like, and who would hear for the first time of such things as the *Fraxinella*, *Trollius*, *Gentiana*,

and the Hepatica. These plants are not fashionable now, and, as a matter of course, are not to be attended to: consequently there are few gardeners who are likely to know them by sight.

The only advice I can give "TOWN-BRED," is to invite all the gardeners and plantmen in the neighbourhood to look at his plants, and, if possible, to name them for him. One may be able to tell him the name of one, and a second of another, till in time he may learn the names of all; for each would be willing enough to impart what he knows, if only to show that he does know something; otherwise there is a work to be had which bears what I consider a high price, yet is not a dear work, it is "Loudon's Encyclopedia of Plants." There is also a work by Curtis, the title of which I forget. These would aid him considerably, if not effect all he desires.

What I should like to know is, the reason why the border-plants of other days are put aside for the sake of the more gay bedders. Are not some of them, at least, useful for massing? Cannot the same thing be done in the flower-borders as is often done in the kitchen garden—that is, can there not be crop and crop between? Supposing a border is to be planted with ribbons of different colours, when they can be put out with safety, why should the ground lie bare till the end of May? Could not a narrow ribbon of the Wood Anemone, and Anemone apennina, be planted, of course to remain? Their tops would die down in the summer, and the ordinary bedders would close over the spaces. They would come up and flower early in the spring, and take off that bareness from the ground which is the most disagreeable part of the bedding system.

There are, I believe, among herbaceous plants many that are adapted to massing, if not for the flower, at least for the foliage, or for their earliness, as in the case alluded to, but I cannot call them to mind at present. Yet I do happen to remember many a gay bed of Primroses which bloomed for three months in the year, and kept in good foliage during the rest; the same with Pansies and Daisies, and Polyanthus and other dwarf plants, which bloomed in a style that would not disgrace the gay beds of half-hardy plants of the present day.

I have a great fancy for the common Anemone, and have seen masses of it that were worth going miles to see, and that in the open ground without any shelter. In fact, the name Wood Anemone seems misapplied here in Worcestershire, where it is now blooming profusely in the open fields, along with the pretty Celandine. This, I believe, is the case with several plants which may be found sometimes growing in woods, but which flower better and last longer without any shelter from trees, or, at least, evergreens, and this ought to be taken some notice of in making plantations of them.—F. CHITTY.

NEW BOOKS.

SELECT ORCHIDEOUS PLANTS.

By R. Warner, F.R.H.S. Cultural Notes by B. S. Williams.

PART IV. is now published, and fully maintains the high character we have previously given the work, both as to the extreme beauty and faithfulness of the portraits, and the fulness of the directions for cultivation.

The present Part contains—1, *Epidendrum nemorale majus*, "without exception, the finest of all the Epidendrums in our gardens," and commonly, but erroneously, named *E. verrucosum*. 2, *Saccolabium violaceum*, "a magnificent plant, native of the Philippine Islands." 3, *Cypripedium hirsutissimum*, "imported about four years ago from India, and first flowered at the Paradise Nursery, Holloway." 4, *Cattleya Dawsonii*, "a very rare plant," which "may be a wild hybrid between *Cattleya labiata* and *C. Mossia*," originally from Brazil. It is justly observed by the authors that it is difficult to keep pace with the rapid rate at which this genus is increased; but we echo their hope that they will "yet be able to bring some other fine acquisitions to its ranks within the compass of the present volume."

THE SCIENCE OF WINDOW-GARDENING.

A Lecture delivered by Walter H. Bosanquet, Esq., at the National School-room of St. George, Bloomsbury, March 31st, 1863. Published by request.

ANY one who from the title of this pamphlet anticipates that it is an abstruse descant on the sciences applicable to plant-culture will have arrived at a very erroneous conclusion. So far

is it from being abstruse, that it is a series of good directions how to grow successfully plants in pots, with the addition of intelligible explanations of the reason why each practice is needful. It is well calculated for the use not only of town window-gardeners, but for other amateur cultivators of plants in pots.

As an evidence that the lecture is practical, we quote the following:—

"The first thing with which you must supply yourself is, of course, a flower-pot; and the first question that suggests itself, What size is most suitable and convenient? I think you will generally find a four or six-inch pot—that is, one which measures 4 or 6 inches across the top inside the rim, to be the most convenient. There is no advantage in using a new flower-pot; but if you use a new one, you must be careful, before making any use of it, to dip it into a pail of water, and allow it to dry. This is done in order to expel from the pores the dry air, which would absorb moisture from the mould, and cause it to shrink. If you use an old pot you must be careful to see that it is perfectly clean both inside and out. At both the Flower Shows which have been held in this parish, I noticed that many of the exhibitors had given their flower-pots a coating of bright red on the morning of the exhibition. This no doubt adds very much to the smartness of their appearance, but it by no means conduces to the well-being of your plants. On the contrary, the lighter the colour of the exterior of the pots, the better will the roots inside them fare, as the light colour will insure a more equal temperature. A pot of a medium colour—that is to say, something between white and red, will, perhaps, be more agreeable to the eye than the former, and more suitable to the plants than the latter. You may, if you like, paint your flower-pots green, or, better still, of a stone colour; and if you adopt the latter colour, and desire to make them look as if they were made of stone, you may achieve your object by sprinkling the paint, while wet, with silver sand. Be careful, however, if you paint your flower-pots, not to make any use of them until the paint is dry."

CRYSTAL PALACE.

THE Directors of the Crystal Palace have issued their programme of arrangements for the tenth season, commencing on the 1st of May. The matured attractions of this popular and delightful place are now in their fullest perfection, and will amply maintain its prestige as the most favoured resort of all lovers of natural and artistic beauty and refined recreation. Hitherto the price of season tickets has been either one guinea or two guineas; the holders of the former class being required on days of special fêtes to pay 2s. 6d. extra for admission. For the present season it has been determined to issue only one uniform class of ticket, at one guinea, and this is to admit the holder to the Palace and park without any further payment, on all ordinary and extraordinary occasions. The Directors have merely reserved to themselves the right of excepting three days during the year, should they hereafter think fit to give some special fête or fêtes which may render a separate charge for admission on those days justifiable.

Among the other arrangements for the forthcoming season are the Great Flower Show on Saturday the 23rd of May and the Rose Show on Saturday the 27th of June. These Shows as conducted at the Crystal Palace, always constitute leading features of the London season, and have the important advantage, as the Crystal Palace has at all times, of being thoroughly enjoyable in any kind of weather.

Last year, notwithstanding the attraction of the International Exhibition, 2,020,219 persons visited the Crystal Palace, and with its varied features and the increased facilities above referred to, an equally large attendance may be fully expected in the ensuing year.

WORK FOR THE WEEK.

KITCHEN GARDEN.

NOTHING gives a more finished appearance to the kitchen garden than clean well-rolled walks with neat edges. If these edges are of Box they must be kept regularly clipped during the growing season. Box-edging is, however, at all times a great harbour for slugs and other vermin, and, therefore, preference should be given to permanent edges of slates, bricks, or some one of the many patterns of Rosher's edging-tiles, if these could be procured. With ordinary care any of these will last for many

years, and if well laid down in the first instance no further trouble is required with them. *Beans*, earth-up the early crops, and where they were put in the ground the latter end of last year, they should be dug between with a fork. Make another sowing. *Broccoli*, all the late sorts to be sown. *Cauliflower*, raise the hand-glasses and loosen the soil between the plants, after which give them a good soaking with manure water. Some of the forwardest of the early-sown Cauliflowers and Cabbage plants will now be in a fit state for final transplanting, which should be done the first favourable opportunity, and in the event of dry weather continuing they must be kept well supplied with water. *Celery*, proceed with the pricking-out of young seedlings, as also the young seedlings of Brussels Sprouts, *Savoy*, *Broccoli*, &c., as they become large enough to handle. *Lettuce*, water the early ones if necessary, and plant out some of the plants raised in the frames or houses. Tie-up for blanching a few of the largest Bath Cos that have stood through the winter. These to be kept well supplied with water during dry weather in order to induce rapid growth, which is essential to the production of that tender crispness so prized in this variety. *Leeks*, transplant from the seed-bed as soon as they are large enough, in rows 18 inches apart and 9 inches plant from plant. The soil cannot be too rich. *Peas*, make another sowing of two or three different varieties according to the consumption. Continue to earth-up and stake the earlier crops; but previous to earthing-up let them be well thinned-out if too thick. This is a more important consideration than is generally allowed. We often sow thick in order to insure a crop, but if all come up and are left, they will grow certainly and bloom and produce a number of small pods, but after a gathering or two they are gone: whereas, if well thinned out a greater weight of finer Peas is produced and they will continue to grow and bloom so as to produce a succession. *Potatoes*, hoe between the early crops as soon as they are above ground. *Scarlet Runners*, sow full crops, and also Dwarf Kidney Beans. *Spinach*, make another sowing the latter end of the week. Attend to the thinning of the early crops. *Turnips*, where there are any grown in frames they will require watering in dry weather, which will prevent them becoming hot and hard. The present dry weather is particularly favourable for the destruction of weeds, and it should not be lost sight of; for, be it remembered, the destruction of one weed now is destroying what would shortly be the parent of many. The same may be said of insects.

FLOWER GARDEN.

The bright, beautiful, and varied hues of lovely green now worn by trees and shrubs, the fresh verdure of the lawn, the choral harmony of the feathered tribes, the bursting buds—all contribute to render this a delightful and most enjoyable month. To the gardener, whether amateur or professional, it is full of promise; already in his mind's eye he views his gay and odoriferous parterre, his trees replete with luscious fruits; and while expressing a devout wish that Flora and Pomona may reward his zealous care, he feels some misgiving as to those blasting visitations of destructive insects vaguely denominated blight. He recalls that his fairest Roses may have "the worm i' the bud," and trembles when he remembers that the aphides sometimes produce sixteen generations in one season. Let all preparations be made for the busy time of bedding-out; determine your plans as to height and colour; pay particular attention to the arrangement of the latter. A flower garden may be richly furnished with plants, but be very ineffective if the colours are badly arranged. For producing brilliant effects in masses reject particoloured flowers; such are never effective. Use pure and decided colours—such as brilliant scarlet, pure white, deep purple, bright yellow, &c. Take care not to mix plants which are of doubtful duration when in bloom with those of a more permanent character, remembering always that the beauty of a formal flower garden depends upon its being in all its details a work of art in which no blemish should occur. There must be high keeping, symmetry, judicious arrangements of colours, traceable to fixed principles, or it will not form a satisfactory whole.

FRUIT GARDEN.

Proceed with the moderate disbudding of Peaches and Apricots. Plums will now require a share of attention in this way by removing all the foreright shoots from the young wood, taking care not to leave more than can be kept well nailed-in without crowding. Continue to remove all superfluous wood from Vines. Stir the surface of the earth well amongst Strawberry plants, and if in a very dry state, give them a liberal supply of water.

GREENHOUSE AND CONSERVATORY.

Continue the necessary attentions to Fuchsias and other soft-wooded plants, which will be required for the conservatory; also, the plants that are now making active growth should be liberally supplied with water. Those growing in prepared borders to be examined to see that the roots are kept sufficiently moist. Take the opportunity of an early hour in the morning to give a good washing with the syringe to everything excepting the plants in bloom. Remove decayed leaves and flowers as they appear. Young specimens of greenhouse hardwooded plants to be kept as moist and warm as can be done without inducing weak growth.

STOVE.

Attend to the training the shoots of twiners as they advance in growth, and do not allow them to get entangled before giving attention. Also, attend to the stopping and training of other plants, and afford free-growing subjects plenty of pot-room. Persevere in keeping down insects, which, if allowed, will progress with great rapidity. Proceed with repotting Orchids as they may require it. Do not use the syringe too freely among those starting into growth, but keep the atmosphere thoroughly moist.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

PROCEEDED with staking *Peas* as opportunity offered. Some of these having between them two rows of *Broccoli* not yet finished, cut off a number of the leaves and bent the plants slightly to each other to relieve the rows of *Peas*. Forked the ground slightly before staking, and as soon as the *Broccoli* and other Greens are wholly removed will fork the ground all over to let sun and moisture freely into the soil. Watered those fit to gather in orchard-house, and the earliest succession of dwarfs at the foot of walls. Sowed succession of Broad Beans and *Peas*. The ground being rather rough and poor where the latter were to be sown, dug it well again, incorporating some rotten leaf mould and leaving the place hollow so that rains may be retained, and waterings given if necessary, whilst the deep stirring will dispense with stagnant moisture—one fruitful source of mildew. Though the *Peas* will thus, when covered, seem to be in a shallow rounded trench, they will be covered no more than usual—say 2 inches, as we have no faith in deep covering. A shrewd practitioner was resolved to have early *Peas*, save them from the frost, and get rid of all the trouble of earthing them up, by sowing them from 9 to 12 inches deep; and in the two latter objects he succeeded admirably, as he was never troubled with them above ground at all.

Sowed *Scarlet Runners*, covering them slightly with light soil mixed with burnt charred earth and lime to keep slugs and worms from them. Sowed Dwarf Kidney Beans in boxes, to be transplanted, as the soil is not warm enough for them out of doors yet, and the weather though fine is getting colder. Expected rain after the high winds of Wednesday, but little or none has come. In about a week will sow the main crop of Beet, and a succession of Carrots. The ground being dry on the surface, neither the first-sown Carrots, Parsnips, nor Onions, are yet rowed clearly enough to admit of hoeing. If rain do not come soon will slightly roll the Onion-quarter to firm the earth about the young seedlings. A slight surface-hoeing afterwards will make them loose enough. Sowed succession of Onions, Lettuces, &c., for salading, and find the warm weather has brought Lettuces and Cucumbers into demand. Pruned and regulated the latter in order that the plants bearing freely should not exhaust themselves by having too many fruit at a time.

Watered Mushroom-beds in Mushroom-house. Will prepare some rough stuff for beds out of doors under a thatched roof, and open in front, as described last year. Planted out last lot of Potatoes on a poor piece of ground. Planted out Cauliflowers that had previously been pricked out, lifting the nice plants with balls so as not to feel the moving; and though this takes more time than using the dibber, there is no flagging and wetting after planting. Took pots of herbs that had been sown under glass to harden-off, and beat up rows and beds of herbs always in demand—as Sage, Mint, &c. The best time to make a fresh bed of the latter, is when the fresh shoots are about 2 inches high. These, slipped off 1 inch below the ground and planted in well-pulverised rather rich soil, about 4 or 5 inches apart, will make a fine green bed in the autumn for late *Peas*. In many soils Mint soon dies out, and, therefore, it is wise to

fresh plant one or two beds every season. But for the trouble and unsightliness there is no better plan of blanching Sea-kale at this season than covering the plants a foot or 15 inches thick with leaves. When pots or boxes are used, a little light is apt to get in, unless the pots, &c., are covered all over with earth. Pricked out Celery; sowed in succession. Pricked out Chilies, &c. Potted succession Cucumbers, and sowed for ridges, and Vegetable Marrows for general crop, as the plants do better when not stunted or knocked about before planting.

FRUIT GARDEN.

Run the hoe through Strawberry-beds and borders, which are now showing their trusses strongly. This will kill incipient weeds, keep the ground from cracking, and let rains go in nicely when they come. Had we such a thing at command we would now give the plants a slight dressing with soot or lime, or both together, as the first will tell on the quality of the crop, and both will keep slugs and worms at a distance.

Some time ago we told of making patent ventilators in the front wall of a Cucumber-pit, the openings being the size of a half-brick, and these were fitted with wooden plugs in the wedge-shape, so that we could give very little air or take out the plug as we liked. As the openings are against the hot-water pipes no plan could answer better for securing a sweet hot atmosphere. But there are few advantages without some countervailing disadvantages; and the disadvantage in this case is that these openings being a little above the outside ground level, mice have got in, and soon let us know they were there. Close to the back wall and the glass of this narrow pit is a shelf of Strawberries that were, if anything, extra promising and just taking their second swelling. In a night or two they cleared them so well that it is not worth while keeping the plants. We should have been apt to have forgiven the mice if they had eaten what they liked, and left the remainder; but the shelf and the surface of the pots were covered with fruit not half swelled which they nipped-off and strewed about for their diversion, after selecting a few of the half-ripened seeds. We trust, as they have cleared away since phosphoric paste and poisoned wheat, that they have been punished for their misdeeds. Fortunately they have not as yet troubled Strawberries ripe or green elsewhere. In using manure water even now for Strawberries, care should be taken that it is clear and not too strong, or it will do more injury than good. The same rule applies to all fruit trees in pots. The amount and the strength of the manure water should depend not only on the wants of the plant, but also on its condition. A plant in full growth with vigorous shoots and swelling fruit will like an amount of nourishment in the shape of strong liquids that would next to glut and render sickly a plant merely swelling its buds or opening its blooms.

Thinned Grapes, tied-up Vines in late house loosely, keeping them still a good way from the glass to guard against sudden extremes, as we do not wish to give them any or much artificial heat at present. Shut-up one orchard-house early in the afternoons, so that it may succeed the Peach-house sooner. In such a case one fruitful source of mischief is not giving air soon enough in the morning. In this house we placed an old iron stove that was lying about after being turned out of some part of the mansion; and though we have had little occasion to light it this season, our previous experience with it and what we have seen of brick Arnott's stoves leads us to the conclusion, that for places where a high temperature is not needed no other plan is so simple and economical. So far as fuel is concerned, a small shovelful will often do more than a bushel either by common flue or hot water, if people would take a little trouble with simple matters. Of course we are glad to see all experiments tried, and we have no fault to find with those who for some little pet greenhouse will have an expensive boiler and a hot-water apparatus which, after all, they find consumes a vast deal more fuel than they were given to believe. Nothing is so nice as hot water for a fine finished greenhouse; but there are many houses where the extreme of nicety is not at all desirable—where keeping plants and fruit and working comfortably amongst them, and a moderate degree of neatness are more wanted than the extreme of elegance and refinement; and in many such places we have not a doubt that a healthy temperate atmosphere may be maintained by a stove with large evaporating-pan for years for something like the expense that would be required to set a hot-water apparatus fairly going. Even for starting the idea of brick stoves Mr. Rivers deserves the thanks of all humble amateur gardeners. With all this we should never think of having anything but

hot water in a large establishment, as combining in such circumstances ease of management with general economy.

Having said this much, we hope that the discussion about flues and boilers and the best boilers, suggested by our friend Mr. Robson, will be attended with some valuable results, though we are not very sanguine on the subject. As to the mere economy of fuel, having had considerable experience with flues and the various kinds of boilers, the result of that experience is, that for moderate-sized houses to be heated singly by a flue or singly by a boiler, and where a somewhat regular high temperature is required, the flue will be the most economical, and if in good order will be just as safe as the boiler and the pipes. When several such houses are to be heated by one boiler, then economy in fuel will be on the side of the hot water, as there is only one wasting chimney instead of many. The chief drawback against this system is that the boiler may fail at a very critical time, and whole crops be ruined before it can be mended or a fresh one put in. At such times the discarded and slighted stove and even unhealthy open pans of charcoal have had to be resorted to.

BOILERS BURSTING.

As we have alluded to the subject we should also, like Mr. Robson, wish for facts as to the wearing-out qualities of cast-iron and wrought-iron boilers. We have heard of a good many of both kinds giving way within these two years. In our own practice the wrought-iron have been by far the least lasting. From what old men tell us there are two cast-iron boilers here that have had rough treatment, and must have been worked for at least thirty years. We have had two wrought-iron ones worn out into holes and to the thinness of a wafer in about fifteen years. Both of these gave way in critical times—the first in the terrible frost of Christmas, 1860; and the second, which heats three pits, gave way early last year, when all the places were filled with plants needing heat.

This reminds us that we have never answered some half a dozen letters as to how we doctored-up this boiler, so that, bad as it was, it is doing its work well now; and we suppose we must let it do so until it collapses again. The boiler was saddle-backed, and some 15 inches deep on the side. On examining the side where the water streamed out into the flue, there, for the space of a foot, the iron was so worn out that we could stick our fingers through it. The dread of having to wait for a fresh boiler made us resolve to tinker it in the simplest manner. The old scaly iron was scraped off, and the side dried, and then well smeared all over where holed and thin with a mixture of red and white lead. An iron plate, some 17 inches by 10 inches, was similarly daubed, and then placed against the side of the boiler, and driven tight home by four pieces of iron being placed across and driven down tight between the plate and the brick-work on the opposite side of the flue. This held the plate firmly against the side of the boiler without rivets or anything else. To make assurance more sure, a row of bricks was laid on the bottom of the flue on that side, holding the plate if anything still more firmly, and with the disadvantage of taking off that much from the depth of the flue, and thus preventing the heated air acting on so much of one side of the bottom of the boiler. Not a drop of water has leaked since, though the boiler has been almost constantly at work; and we suppose that now we will go on with it until the other side give way. Of course, if the leakage had happened in summer, common prudence would have said, "Have a fresh boiler at once;" but at the season it occurred we must have lost many things before the boiler could have been taken out and a fresh one put in and the connections made. All the top-arched part of the boiler was as good as ever it was. We feel sure that our fresh-plated part though merely squeezed on will be the last to give way.

This patching may be interesting to some one in a similar difficulty, and we have no doubt such patching could often be done if the wornout or defective part could be got at, which opens up the whole question of exposed boilers, and on that, too, much information is wanted—such as how best to work them so as to secure all the heat they give off, and yet feed them from outside the house.

ORNAMENTAL DEPARTMENT.

Proceeded with potting and planting much the same as last week. Out of doors the chief work was rolling the lawn, and chiefly the sides of walks, mowing these especially, and cutting afresh with line and edging-iron the sides of the walk, as if done well now the shears will do all that is necessary during the season, and much more easily from the cutting now; but taking

off as little as possible, a straight line and not a raw edge being the object. In addition turned over the soil of beds, and nearly finished digging flower-borders.—R. F.

TRADE CATALOGUES RECEIVED.

F. Boshell, 86, High Street, Borough, London.—*Descriptive Catalogue of Dahlias.*

A. Verschaffelt, 50, Rue du Chaume, Ghent.—*Nouveautés pour 1863.*

TO CORRESPONDENTS.

ANEMONE (Subscriber, Dublin).—It is *Anemone hortensis miniata*, or Red-flowered Garden Anemone. The species of which it is a variety, *A. hortensis*, is a native of Italy, and has striped petals.

GRASS SEED (Jesse Carter).—Not knowing anything about the Grass, and not being able to foretell whether seed will be scarce or plentiful, we cannot say what the value is. You had better send full particulars and a sample to some wholesale agricultural seedsman.

HEATING BY GAS (G. A.).—Either plan will answer for heating the little boiler by gas; but we have great doubts of such small pipes giving you the heat you require, or of the boiler and pipes all of tin lasting any time. We would have as much faith in the heated air from the gas passing through one-inch pipes. If you attended to it yourself, we have no doubt you would make your very ingenious plan answer. For economy and certainty we would prefer a small stove close to the back wall. It would cost a trifle in comparison of the gas and pipes.

REPOTTING ORANGE TREES (Subscriber).—We would repot the Orange trees with the fruit on them as soon as convenient if they require it, and keep them in theinery for a few weeks afterwards. 80° would be high enough for them, and they must be hardened-off by degrees to the temperature of the greenhouse or conservatory. They will root best in a high temperature.

VINE LEAVES SPOTTED (A New Beginner).—We should think from the leaves that the roots of the Vines are too moist, and that little sun strikes the soil in which they grow. We hope that your border of 3 feet deep is drained; if not, it would be advisable to drain it next season, or even this; but perhaps it would be best to raise the Vines early in the autumn and put a foot of rubble below the roots, which would leave 2 feet for soil—quite enough. We see no reason why the Vines should not do; but care must be taken not to sodden the border with water from the plants standing over it. It would be well, especially in winter, to have flats or pans for such plants. Vines will do very well planted against such back wall, and trained down under the roof; but the more sun strikes against the soil at the back wall, the better will the Vines do.

HOT-WATER PIPES UNDER OR OVER A DOORWAY (B. C. W.).—If your kitchen boiler had been against the back wall of your greenhouse there would have been no difficulty; but being near the wall on the opposite side does away with most of the economy of the affair. The boiler being raised considerably above the floor of the kitchen, and the floor of the kitchen and the conservatory being on the same level, also increase the difficulty. If the top of the boiler had been sunk a foot beneath the kitchen floor, all would have been smooth sailing. The position of the pipes in the greenhouse are below the level of the boiler, and you cannot heat in that manner. There will be no difficulty, except the inconvenience, in getting the pipes through the kitchen, if the lowest pipe in your greenhouse is higher than the top of your boiler. You may then take a flow-pipe from the top of your boiler into a cistern on the same level as your present supply-cistern, or as much below it as you like, provided it is higher than the top of your boiler—5 or 6 feet will do very well—and from that take your flow-pipe, descending to any suitable level, provided it is higher than the top of your boiler. This pipe may go round the house, or return; but the lowest pipe also should be as high as the top of the boiler, and from that lowest point the return-pipe may descend and pass under the kitchen floor, and rise to the bottom of the boiler, and thus avoid the doorway, having an open air-pipe at each of the bends. But though this might answer, we should prefer that the return-pipe from its lowest point should go through the wall, go round the wall of the kitchen on that level, above the level of the boiler, and then descend at once to the bottom. The pipe, if desirable, when going round the wall of the kitchen, could be boxed-up. This would be better than sinking below the boiler.

SEEDLINGS (A Young Subscriber near York).—Good border flowers, but not superior to others already in cultivation. Nothing novel about them.

YUCCA FILAMENTOSA NOT FLOWERING (E. H.).—The last three years have not been so favourable for *Yuccas* blooming as the three preceding seasons, and we fear your having removed your plant lately will not favour its blooming this season, although it is likely it will facilitate its doing so another year. We have had as many as a dozen spikes of *Yuccas* out at a time, and no flower that we are acquainted with looks more noble. The spike of *Y. filamentosa* is about 3 feet or more high, and thickly set with cup-shaped bloom of a creamy bluish colour. *Yucca gloriosa*, *aloifolia*, and *recurva* are much larger, spikes of 8 feet and upwards being not unusual. The individual blooms are much the same in colour as *Y. filamentosa*, but more bulky and numerous. They flower best in a dry sunny situation and on dry or chalky soils. There is no fixed time for their flowering, for we have had flower-spikes rising in October, and, of course, were cut off in winter, and we have had them early in May. Where there is a number of plants they flower at irregular times. We should think that, unless the bloom-buds of your plant were formed during the fine weather of last autumn, your shifting it lately will prevent its blooming this year; but it may be otherwise. Hot dry summers and autumns suit this plant, and you will doubtless be favoured with a bloom from it in due time. The plant in bloom you send is *Phlox setacea*; the other not in bloom seems a *Saxifrage*, and most likely *S. hypnoides* or *S. tridactylites*.

FLOWER-GARDEN PLAN (An Amateur, Fareham).—The only change we would recommend is to cross your colours at the sides of the diamonds, instead of having all warm on one side and all cold on the other. Thus make 9 and 19 *Gazania*, and 10 and 18 *Lobelia*, or dark *Calceolaria*, and so on.

DOUBLE PURPLE PERIWINKLE (M. S.).—Yours is the double variety usually met with. We cannot tell whether our Worcester correspondent would exchange some of his double blue for some of it.

DOUBLE AND SINGLE VIOLETS (E. H.).—After the double Violets have done flowering, scatter a little sifted leaf-mould amongst the shoots, which will encourage them to root, when, some time towards the end of May, the self layers may be taken off in showery weather and planted in some suitable place. The old plants may be trimmed back into tufts somewhat larger than they were the year before. This trimming, however, had better not be done until the growth of the season is nearly completed, after which the blossom-buds will be formed, and they may at the same time be treated to judicious doses of liquid manure. The name of your plant No. 1 is lost, but No. 2 is *Coronilla glauca*.

CUTTING BACK PEACH AND NECTARINE TREES (J. H.).—Although the blossom has not set, it would not be advisable to cut them much back if they are in a vigorous condition and no fruit on them, or they will produce wood much too gross to expect much fruit next year. At the same time, if last year's wood was not sufficiently thinned, a part may now be cut away with advantage. The great thing is to balance the number of shoots of the current year with the support afforded them by the root, so as to insure healthy well-ripened wood of a uniform size in all parts of the tree, and none of it too gross and succulent. A too-severe cutting-in may induce the latter if the trees be vigorous, while, if otherwise, they will be benefited by a timely pruning.

THRIPS ON CUCUMBERS (An Old Subscriber, Mrs. E. T.).—Heat and dry atmosphere are the delight of the thrips; successivesmoking with tobacco, and frequent syringings and a moist atmosphere the chief cure. We would remove a good many of the infested old leaves and burn them; but at this season we would raise young plants in another place, and when strong get rid of the old ones. There are many modes of keeping them down, as catching them with a moist finger, but they are difficult to get rid of. The advantage of having a canvas blind is the using it only in bright sunshine. We would leave it off at night, and evenings, and mornings, before the sun became strong.

FLOWER-GARDEN PLANS (H. D. C.).—You deserve credit for the mode you have attempted to colour your beds in. The first group is very nicely arranged, as to ground plan, there being a hexagon for centre, six pointed ovals round that, and six rounded triangles round them, the points coming in the openings between the ovals. Such a group is just made for balancing; and if, after what has been said on planting flower gardens generally, it pleases you to have all these thirteen clumps different, why you have a perfect right to please yourself. You would also see what has been said of *Roses* for a centre lately; but you could relieve yours by *Stocks* and *Asters*; we would have the *Stocks* outside instead of the *Asters*. The outside of the six ovals, being of *Cerastium*, will give an idea of sameness; but they will be a considerable distance apart, and that will relieve them. Four of these beds are to be filled with *Verbenas*, one with *Heliotrope*, and one *Carrots* and *Phlox Drummondii* mixed. The other six beds are also all different, and on the system you have adopted we think the result will be very good, though every separate bed is distinct and different, there being no pairing or balancing. We cannot say, however, that we like the idea of *Carrots* in a flower-bed, however pretty the foliage. There is such a difference in admiring the merely beautiful, and thinking of the accompaniments of boiled beef. We do not like the plan of No. 2 nearly so well, there is too much likeness in form to the first. The two No. 3's seem also to be offshoots, destroying the regularity of the figure or group; and, then, it has no centre to fall back upon as it were, otherwise we like the system of balancing better; and as you have done this with 1, 1, 2, 2, 3, 3, so as, we are sure, to look well, we would carry this system out in all this figure by pairing 4 and 6, 5 and 7, and 8 and 9. The two groups will be planted then on two systems. We have no doubt your ribbon-borders of four rows *Punch Geranium*, *Red Beet*, *Calceolaria Aurea floribunda*, and *Cerastium* and *Lobelia* mixed, will please many. For our part we would prefer purple *Spinach* or *Perilla* to the *Beet*. It will be so apt to conjure up ideas of a well-dressed salad.

INSECTS (W. Hallett).—The black insect is the destructive *Otiorynchus sulcatus*, which must be sought for after dark, a cloth having been previously spread under the Vine. On the approach of a light it falls to the ground, and must be destroyed. The pale-coloured insect is the common cuckoo spit insect, *Ophrophora spumaria*. It is only an accidental visitor to the Vine.—W.

NAMES OF PLANTS (W. Taylor).—*Erythronium dens-canis*, or common Dog's-tooth Violet. (*Anne*).—The blue flower from the wall is *Linaria cymbalaria*; but, not being magicians, we cannot tell the name of an *Acaia* from a single leaf. (*Novice*).—1, *Edwardsia microphylla*; 4, *Pernettya mucronata*. The other specimens are not even in leaf! (*An Amateur, Londonderry*).—*Muscari moschatum*. 1, *Polystichum aculeatum lobatum*; 2, *Lastrea æmula*. We do not know that the variegated Japan Honeysuckle has been tested, but the species of which it is a variety is generally considered hardy enough. (*Alumnus*).—The numbers were nearly all displaced. The box contained not *Primula elatior*, but *P. vulgaris umbellata*, *P. veris*, *Adenandra uniflora*; 4, *Doronicum*, perhaps *plantagineum*, but you have not sent root-leaves; 5, *Ranunculus amplexicaulis*; 6, *Arabis albidula*. (*E. M., Sandymount*).—*Ribes speciosum*. (*A. L.*).—*Berberis aquifolium*, *Pyrus* or *Cydonia japonica*. The first would do in a shaded border; the other is more suitable for a wall or trellis.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

WHICH OWL DESTROYS GAME?

YOUR correspondent, W. H. Beadon, inquires which owl destroys game. Mr. Warren the head gamekeeper here (Thornham Hall) informs me that he has seen the horned owl take away young pheasants, and also that he saw the barn owl with a young rabbit in its clutches on the branch of a tree. The above facts are, I think, sufficient proof that owls like a taste of game; and why should such beautiful specimens of the feathered tribe be deterred from tasting some of the good things amongst which they dwell? What can be more lovely than to

rise between 4 and 5 A.M., and to listen to the beautiful music of the feathered tribe?—the blackbird, with its rich mellow notes, trying to out-do all its neighbours; this black-feathered gentleman is particularly fond of a good feast of Strawberries, and richly he deserves it. Let us therefore be "true protectionists," and preserve both birds and fruits, not forgetting to leave a few for the poor blackbird.

Old towers, summer-houses, and such places are much frequented by owls; and many a would-be-destroyer of this noble bird has been caught with a pail of water.—JOHN PERKINS.

VIRGIN QUEENS CAN CERTAINLY PRODUCE PERFECT DRONES.

MR. LOWE is quite correct in stating that the progeny of virgin queens are generally extremely puny from being bred in worker cells; but this is also the case with the male offspring of impregnated queens when produced under the same disadvantage. I know not whether "B. & W." may have adopted a similar precaution; but in my own case I have taken care to supply the virgin queen referred to in page 270 with drone-combs, and the result is that she breeds as large and handsome drones as can possibly exist under any circumstances.

With regard to the doubt expressed as to the value of such drones in queen-rearing, I have already proved beyond question by careful anatomical investigation that the progeny of virgin queens are perfectly capable of propagating their species. As to the details of this examination it is unnecessary to repeat them here, since Mr. Lowe may readily refer to them in Nos. 30, 31, and 37 of the new series of THE JOURNAL OF HORTICULTURE.

In conclusion, I can fully indorse all that he has stated with regard to the apiarian disasters of the past winter and early spring. I believe that in many districts bees have become nearly extinct.—A DEVONSHIRE BEE-KEEPER.

BURYING BEES.

THE year before last I procured a swarm of bees, and placed them in one of Neighbour's cottage-hives. This hive stands in a wooden receptacle constructed for it, and faces the south. Although the bees worked well apparently during the autumn, they yielded me no honey. During the winter I fed them, and last year they threw a swarm, which I hived and placed alongside the first-named one. From neither of these hives did I get any honey. In November last a friend advised me to bury the two hives in the ground, and assured me that the bees would require no feeding, and commence breeding much earlier than they would do by any other treatment. I resolved to try the experiment with the "Neighbour's hive," and accordingly buried it about a foot underground. On digging it up about the beginning of March, I found that the hive was filled with dead bees, most of them in a state of decomposition, and the comb quite spoiled. Supposing that my ill-success arises from my own mismanagement in some way, may I ask you to inform me how I erred? That burying the bees, though not, I believe, generally practised, proves in some cases successful, is clear from this paragraph cut out from a newspaper this week. It is the only authority I can refer to in print, though I have on other occasions heard the practice recommended.

"BURY YOUR BEES.—In the fall of last year, Mr. John Finlayson, of Cumbernauld, who had experienced great difficulty in preserving hives of bees during the winter, resolved to enter on an experiment with the most weakly hive in his stock. This he buried beneath a foot of earth in his garden; and though the bees in the other hives, which were protected in the ordinary way, all died, those in the buried one were on their disinterment on Tuesday last, found to be alive, and at once commenced to buzz about."—(Scottish Farmer.)

I have now one hive (last year's swarm), but the bees are not very active. It is fortunate for me that I did not bury both hives. How ought I to proceed to make this one hive prolific?—N. CLAYDON, *Lowick, Lancashire.*

[Many years ago several of our contributors tried the experiment of burying bees, and generally with the same result as in your case. Very few survived, and those were in a very weak state. Such newspaper paragraphs as you enclose do infinite mischief to the inexperienced by recommending what has long been exploded. Burying bees is quite unnecessary in this climate, and where it is habitually resorted to in order to elude the

intense cold of northern winters the pile of hives is only partially sunk beneath the surface, the projection being well thatched, and every precaution taken to keep them dry by thoroughly good drainage and ventilation.]

OUR LETTER BOX.

FERTILISATION OF EGG (*Eliza*).—The probability is that the next day but one after running with the Brahma Pouter cock, the egg would have been available for sitting; but certainly all after that date may be employed.

REARING SILVER PHEASANTS (*J. P.*).—The best bird for rearing Silver Pheasants is a small hen. We do not depend on a Silver hen to sit on her own eggs. They will not always do so, nor are they careful mothers. We have one at the present time sitting close on nothing: she has been thus employed for more than a fortnight. As soon as some of our hens begin laying again we intend to treat her to three or four eggs, but our experience is not much in favour of her rearing poults. We, however, think her a better bird as a sitter than a common hen in confinement.

CHICKENS REMAINING WITH THEIR MOTHER (*C. L.*).—In the winter chickens should remain under a rip with the hen longer than in the spring or summer. In the spring six weeks are long enough. In the summer still less time will do. The hen is wanted principally at night to cover the chickens and keep them warm, and as the nights become short and warm chickens are less dependant on the mother. Yours will therefore do very well. Chopped pieces of cooked meat are very good. Instead of putting the hen with ducklings under a coop, shut her in an old pigsty or some such place, and she will do very well. Ducklings are not active enough to be under a rip, and webbed feet are not favourable to confinement. They will not do by themselves at three days old. Cochins pullets under favourable circumstances lay at from sixteen to twenty weeks old; Game and Dorkings from six to eight weeks old.

LICE ON FOWLS (*J. P.*).—Yours seems a singular case. We have never known one in which dust did not destroy these pests. If you will put heaps of dry dust, the finest you can, add thereto black sulphur at the rate of 1½ lb. to the bushel, and place the whole so that the heap shall be in the sun, we think you will be free from torment. It is the law of nature that all birds shall use the bath—some water, some dust—but both for the same purpose, to rid themselves of vermin. If you know of a spring that runs across a lane in a tolerably quiet neighbourhood, and winds and frets its little way over, around, and among gravel stones, you will in the middle of the day find it full of small birds washing with might and main, till at last they are all a like colour, disappearing in the thorough wetting. If you are a sportsman, or if you are an observer of the habits of birds and fond of natural history, you will find at midday, on the dusty banks, pheasants and partridges basking, with one wing up and their feathers open. They are not content with half measures; they fidget and scratch and twist till they are half buried. When you have disturbed them you will find each was half buried in the finest possible dust, and the clouds that fly from them as they take wing will show how thoroughly they enjoy their bath. It is a necessity, and it accomplishes for them that which you want for your chickens. In a very wet season, when there is hardly a dry place to be found, all these birds are infested with lice; and if there be a beetling bank intersected by the roots of old trees, you will see by the works they have found it out, and, although no sun penetrated, they have dusted there. If the remedy we have suggested fails, then lime-white the houses thoroughly, especially the corners, new gravel the floors, and close them against the poultry. Let them for a time seek fresh roosting-places and scatter themselves about. If that will not do oil their feathers on the crown, under their wings, and on the back. This is the last remedy, as it spoils the plumage for a time. Feed them lightly on ground food, and if you have used rice or meat discontinue both.

CHICKENS DYING SUDDENLY (*T. G. & Co.*).—Your chickens pick up something that kills them. We know no disease that would kill them as rapidly as you describe.

HENS WITH WOUNDED BACKS (*G. Y.*).—Separate the cock from them until their backs are healed. Dress the wounds with merely a little iard to exclude the air.

POULTRY LOSING THEIR FEATHERS (*L. T. B.*).—We are afraid you are like many of our friends—you are killing your fowls with kindness. The Spanish lose their feathers either from internal heat from over-feeding, or from diseased insides: they pick the feathers one from the others. The origin of the Dorking disorder is the same. As these things exist in your yard, and as we will engage the nearest farmyard is free from anything of the sort, we advise you to do as they do. Cease to overfeed; that disorders the birds, and from repletion they do not seek the natural foods and medicine the earth teems with on its surface. Do not take so much care of them. Let them rough it, forget to feed them sometimes, and give their meals so that they must seek them. If they have been fed from any vessel, remove it at once and let them pick everything from the ground. If one hen in particular pecks the feathers of the others remove her, as they soon acquire bad habits.

APIS DORSATA (*W.*).—Except as a matter of curiosity, it would be absurd to import this Indian honey bee even if it were practicable, as, unlike our domestic bee, *Apis mellifica*, it is very confined in its geographical range, requiring an Indian climate.—W.

FALLOW COMBS (*R. G. P., Sudbury*).—The best plan would be to invert the hive during the middle of a fine day and replace the combs in their original position, supporting them on either side, and at their original distances apart, by inserting strips of old comb about half an inch wide between each. Then lay three or four strips of the same material, cut sufficiently thick to keep the combs in firm contact with the top of the hive, transversely across them; and, covering the whole with the floor-board, invert it and put the hive in its place. If you cannot manage this the fallen combs must be taken away and the stock liberally fed, in order to enable the bees to supply their place as soon as possible.

UNDULATED EUPHEMIA (*A Great Lover of Birds*).—Canary seed is the usual food for your birds. When they have young add boiled egg, millet and maw seed, and let them have a bunch of long grass, when in seed, hung up. Place in the cage, at one corner near the top, a small box about 5 inches square and 4 deep, with the nest already shaped, composed of dry moss, grass, and wool, similar to what canaries build with, with some loose in the cage. See our Journal, New Series, No. 50, "The Breeding of the Australian Grass Paroquet in England."

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 61.5° and 39.5° respectively. The greatest heat, 81°, occurred on the 6th, in 1830; and the lowest cold, 21°, on the 8th, in 1855. During the period 147 days were fine, and on 105 rain fell.

ANNUALS.

O obtain a fine show of brilliant colours at but little trouble and expense, there is no plan that can compare with growing a good selection of annuals in the flower-beds and borders. This subject has been brought before me rather prominently, by a letter from a gentleman, wishing to know how he may fill up the gaps which he sees he will have in his beautiful flower garden this season. He wishes me to tell him what sorts would do to sow now in the end of April and the beginning of May in the open ground, so that he might expect them to keep on gay for the most of the season. With the exception of those sown in autumn, or very early in the

spring, this is the time when I generally sow those I wish to bloom through the autumn. To suit other inquirers besides our correspondent, I will divide my lists into several sections, with a few running remarks on each.

1. Annuals sown in April and the first week in May, to keep on for the season.

Alyssum maritimum (Sweet Alyssum), 9 inches.

Atriplex hortensis rubra. For mixing or edgings.

Amaranthus—Prince's Feather, Love-lies-bleeding.

Bartonia aurea, 1 foot. Golden poppy flower.

Calliopsis tinctoria, atropurpurea, marmorata, nana, and lots of others. Drummond's makes a fine bed, and so does Burridge, and indeed all of them. From 2 feet to 2½, except nana, which is about 1 foot.

Callirhoe digitata and *pedata*, very pretty, rose and white, 1½ foot.

Campanula speculum, 1 foot; and *Lorei*, blue and purple, 1 foot.

Clarkia pulchella (rose), alba (white), integripetala, and others, 1 foot. Very pretty; require pruning seed-pods.

Collinsia grandiflora, purple, 6 inches. The only one that will stand.

Chrysanthemum tricolor and *aureum*, 1½ foot.

Convolvulus minor, dark-striped; monstrosus, good for edgings, 1 foot.

Convolvulus major. Varieties for climbing.

Delphinium, blue and purple, and variegated branching Larkspurs, 2 feet.

Eschscholtzia californica (yellow), 1 foot; crocea (orange), 1 foot; tenuifolia, 9 inches, pale, showy, poppy-like flowers.

Eutoca multiflora, viscida; rough, but the colours fine, 2 feet.

Godetia roseo-alba, Lindleyana, rubicunda, very fine, 2 feet.

Will keep on to September. To prolong blooming half the plants should be nipped over when 4 inches high, or the seed-pods picked off.

Helichrysums, white, rose, yellow, 3 feet. Everlastings.

Kaulfussia amelloides, blue and white, 1 foot.

No. 110.—VOL. IV., NEW SERIES.

Lopezia racemosa, miniata, 6 inches, rose.

Lupinus nanus, 1 foot, blue and white; *Menziesii*, yellow, 1½ foot; *mutabilis*; *Cruikshanki*, blue and white, 4 feet; and many others, such as *Dunnetti*, and *superbus*, besides the blue and yellow annual *Lupines*, the last standing well.

Malope trifida, *grandiflora*, purple and crimson, very gay, 3 to 4 feet in height, and better than the varieties of

Lavatera, white and lilac, but which look well in back rows, 3 to 4 feet.

Mimulus, mixed varieties, from 6 to 18 inches. Do well in a moist, shaded place.

Nemophila, of sorts, if sown again in the end of June.

Malcomia maritima (Virginian Stock), red, white, and pink, if sown repeatedly.

Oenothera micrantha, 1 foot, yellow; *Drummondii* nana, 1 foot; *bistorta Veitchiana*, 9 inches, neat, and pretty orange colour.

Perilla nankinensis, purple foliage.

Sanvitalia procumbens, ½ foot, yellow and black.

Saponaria calabrica (pink), alba (white), marginata (pink and white). Fine for dwarf beds and margins.

Schizanthus pinnatus, *Priestii*, pulchellus, about 2½ feet; rosy, pink, white, and lilac.

Reseda odorata (Mignonette).

Schizopetalon Walkeri, white, a few inches high, makes a pretty edging.

Silene. The various coloured *Catchflies* about 18 inches in height, and such low species for small beds and edgings as *pendula* (pink); alba (white); *pseudo-Atocion* (pink); *pulchella*, ditto; *rubella alba*, and *Schafta* (rose and pink).

Sphenogyne speciosa, 9 inches, pale yellow, upright growth, and fine pinnated foliage. This and the *Silenes* will require the seed-vessels to be pruned away.

Tolpis barbata (Yellow Hawkweed). Makes a fine bed or edging.

Tropaeolum majus. The strong-growing kinds for fences, stakes, or covering the ground amongst Dahlias or shrubs; the dwarf and Tom Thumb varieties for beds and edgings, as *Tom Thumb Scarlet*, *Yellow*, *Pearl*, *Crystal Palace Gem*, &c., well diseased, will equal *Geraniums*. *Canariense* is also fine for fences, chains, running over trees, or may be trained as fine yellow edgings.

Lathyrus odoratus, or Sweet Pea, will also do well as back rows, but it would be as well to sow again in front of the first, in the middle of June.

Viscaria oculata (pink), *Dunnetti* (white), about 18 inches, and nana of both, about 6 inches. These will want the seed-vessels to be nipped off.

In fine, pulverised soil these may be sown any time, taking care not to bury the seeds. Small seeds should just have a sprinkling of soil to keep the fierce sunlight off them. In harsh, cold, clayey soils, well dug, but rather rough, a shower would shatter it like lime; then break it fine, and draw ruts for the seeds in proportion to the depth wanted. In such circumstances we would draw the little ruts double the depth wanted. Scatter the seeds rather thinly, and if the ground is dry water the places with a fine rose, and then cover, if with a little fine soil all the better, but leaving the little ruts only half filled, which will be found a good plan if a future watering should be desirable, or if a little rough charred earth and lime should be found necessary for throwing among the seed-

No. 762.—VOL. XXIX., OLD SERIES.

lings to keep slugs and worms from them. The chief drawback to this plan will be the birds, which, if they do not eat will be apt to scratch the seeds, and thus spoil the unity of your arrangement. The remedies are covering the seeds with pots, with tree branches, or with nets, until the seedlings are well up.

Even then, however, there will likely be some vacancies; and, therefore, as a reserve, it would be well to adopt the plan of a correspondent, and sow in pans or pots under glass. For myself I would prefer placing 3 inches of rough soil and leaf mould on a hard bottom, and 3 inches of light fine soil over it; sowing the seeds rather thickly, covering with glass until they were well up, hardening them off by degrees, and lifting them in patches to where they are wanted.

The greater part of these annuals might also be sown in March and the first days of April; but, as a rule, they will not come up so regularly, nor will they bloom continuously so late. When it is desirable to have them as early as possible, and the late-flowering is a matter of less moment, then make up a slight hotbed in the middle of March, cover with rotten dung and soil as stated above, dig and pulverise the ground well, and plant out in patches about the end of April. The best beds and margins of annuals we ever had were so managed, and though they bloom sooner, they will not continue in the autumn like those sown now in the open ground or under a little protection and transplanted.

2. Selection of annuals to bloom early in spring, by sowing in the third week of September, either where the plants are to stand or thickly on a border, hard below with about 4 or 5 inches of rather poor stiffish soil, which will lift in lumps early in the spring, or in the beginning of winter after the beds are cleared, well dug, &c.

Alyssum maritimum (Sweet Alyssum), white.

Anoda purpurea, 1 foot.

Cacalia coccinea aurea, 1 foot.

Calandrinia speciosa, rose, 6 inches.

Callichroa platyglossa, yellow, 9 inches.

Calliopsis, all the best, as mentioned above, except *Drummondii*, which rarely stands the winter.

Campanula, all the dwarf kinds, *Venus's Looking-glass*, &c.

Clarkia, the whole of the varieties; the pulchella group is harder than the elegans varieties.

Collinsia bicolor, *bicolor alba*, *bartsiaefolia*, and *bartsiaefolia alba*, *grandiflora*, *marmorata*, and all the species and varieties.

Collomia coccinea and *grandiflora*, red and saffron, 1 foot.

Delphinium, dwarf Rocket Larkspurs.

Eschscholtzia, all mentioned in previous lists.

Gilia, all from 1 to 1½ foot in height. The varieties of *tricolor* are best; but all the varieties of *achilleaefolia* and *capitata* are also good; the latter in good soil will reach 2 feet. Is a little rough.

Godetia, all previously mentioned, and as many more as may be deemed advisable. These sown in autumn might be planted thinly in beds, and bedding plants placed between them to fill up when the first were done blooming.

Iberis, all varieties of annual Candytufts.

Leptosiphon androsaceus and varieties, *aureus*, *densiflorus*, *luteus*, &c.; low-growing pretty plants.

Limnanthes Douglasii and others, as *grandiflora*, *rosea*, low things with yellow and rose flowers.

Lopezia coronata, rose, 1 foot.

Malcomia maritima (Virginian Stock).

Nemophila, all are suitable.

Nigella, all varieties, but best sown in spring.

Nolana, all varieties, best sown in April.

Papaver (Poppies), best in spring.

Sanvitalia procumbens, best in spring, black and yellow, 4 inches, trailing.

Saponaria calabrica, all varieties.

Silene, ditto, as already mentioned.

Viscaria, varieties.

Tolpis barbata (Yellow Hawkweed), best in spring.

Venus's Looking-glass of colours, blue, bluish, white, &c.).

These will need the protection of a few evergreen branches amongst them in severe weather in winter. The next best plan with these would be to sow in the open ground early in March; but they will bloom much later than those sown in autumn. A better plan to secure early and uniform beds in spring and early summer from spring-sowing, would be to sow in a mild hotbed early in March, with rotten dung below and fine soil above; then harden-off and fill the beds or rows, not with solitary plants but

with patches, rooted in and adhering to the rotten leaf mould and soil. The transplanting will promote dwarfness and free-blooming. Where there is the convenience of a few sashes early in the spring, this plan will often secure fine beds with less trouble than sowing in autumn. Autumn-sowing is the best plan for early blooming, where such conveniences as sashes cannot be had in the spring.

3. Annuals that require the assistance of heat and glass to give them a chance of forming a prominent part in the adornment of the flower garden. We shall divide these into two classes—those that are best sown in pots, and those that may be sown in boxes or on a mild hotbed. The first will also be the better of more heat than the second, and both will need pricking out as soon as they are large enough, unless sown sufficiently thin at first.

Those best sown in pots, are such as

Abronia umbellata, rose, 6 inches.

Acroclonium roseum, rose; and *album*, white. Everlastings. 1 foot.

Ageratum, chiefly the *mexicanum* varieties, as *nanum*, which is dwarf; *odoratum* and *celestinum* are next best.

Alonsoa grandiflora, *Warzewiczii*, scarlet, 2 feet.

Amaranthus bicolor, *tricolor*, 1½ foot.

Anagallis grandiflora, *Breweri*, &c.; blue; and other varieties, red, lilac.

Arctotis grandiflora argentea, silver leaves, yellow flowers, dwarf and creeping.

Browallia varieties, chiefly for greenhouse.

Calceolaria varieties.

Chaenostoma fastigiatum, rose, low, a few inches.

Cineraria maritima, silvery foliage.

Cleome brachysperma, white, 18 to 24 inches.

Clintonia elegans, *pulchella*, &c.; resembles *Lobelia* of the dwarf kinds.

Cobaea scandens, strong climber.

Cucumis, ornamental Gourds.

Cuphea of kinds.

Datura chlorantha, *Wrightii*, &c.

Dianthus, of the *Heddewigii* and *laciniata* group.

Eucnida bartonioides, yellow, 1 foot.

Heliotropium, varieties.

Humea elegans, for centres of beds and greenhouse; does best sown in small pots and potted on before planting.

Isotoma axillaris, blue, 1 foot.

Linum flavum and *grandiflorum*, &c.

Loasas of kinds, dangerous climbers.

Lobelia speciosa, and many other kinds.

Martynia fragrans, 2 feet.

Maurandya of colours, for pillars, climbers.

Mesembryanthemum of kinds and colours.

Nemesia floribunda, *versicolor*, and varieties, pretty low plants, white, yellow, and blue.

Nirembergia gracilis, *intermedia*, the first light lilac, the second purple, 1 foot or rather 9 inches in height.

Nycteria selaginoides and varieties, pretty low plants, looking like *Lobelia* at a distance, pinkish, bluish, white.

Oxalis rosea, a few inches high.

Perilla nankimensis, to have it strong.

Portulaca Thellusoni, and many varieties.

Primula sinensis varieties, for greenhouse.

Rhodanthe Manglesii, *maculata* (Everlasting flowers), rose, crimson, and yellow, 1 foot.

Ricinus of kinds, for fine foliage.

Solanum capsicastrum, for greenhouse, chiefly for the fruit.

Verbena venosa, *Aubletia*, and all varieties generally. The sooner they are sown the better they will bloom.

In the case of most of these, and especially as regards all the small-seeded ones, as *Lobelia*, *Calceolaria*, and *Portulaca*, we would fill the pots half full with drainage, then rough soil, then fine soil, gently pressed, water well a day before, sow the seeds on the slightly-dried surface, put a square of glass over the pot, and shade until the seedlings begin to appear. For all such small seeds the slightest covering of fine sandy soil should be given. In pricking-off, we often do so in little patches instead of single plants, which is easier done. None of these small seedlings should be watered overhead, but when dry, if not soiled as above described, the water should be poured in on one side, such as on an oyster-shell, so that the soil may be moistened without wetting the tops, or beating them down from the rose of the watering-pot, as that will make them damp-off to a certainty.

Larger seeds will require more common treatment; but from want of attention to minutiae, we have known seeds saved from the same plant distributed to several people, and some would raise plants from almost every seed, and others would not succeed in obtaining a plant.

Annuals to be sown in a gentle hotbed, hardened-off, and finally transplanted.

Antirrhinum majus and varieties will bloom in autumn.

Argemones, of species, must be planted young.

Blumenbachia insignis, blue.

Chrysanthemum, annual varieties, as *tricolor*, *aureum*, *Burridgii*.

Dianthus, as *chinensis*, and varieties of Indian Pink, &c.

Gaillardia, such as *pieta*, *nana*, &c.

Helianthus, double Sunflower.

Holcus saccharatus, for foliage.

Impatiens, garden Balsams, which thus treated make fine bushes.

Lophospermum, of sorts. Climbers; better, however, in pots.

Myosotis palustris and *azorica*, common and Azores Forget-me-not.

Nolana sub-cœrulea and other varieties.

Mathiola, the best German and large-flowering Ten-week, and other Stocks.

Pentstemons, different species and varieties, as *gentianoides*, *Murrayanus*, which thus will bloom as annuals.

Phlox Drummondii, many varieties, all beautiful.

Salpiglossis, many varieties. Make telling beds. About 2 feet in height.

Salvia coccinea and *Rœmeriana* are the chief kinds that will bloom freely the same season from seed.

Zinnia elegans, varieties, would make beds or rows of themselves; and the scarlets, crimson, and purples, are exceedingly beautiful. To these may be added the Peony and *Chrysanthemum*-flowered French Asters, and the Quilled German Asters, African and French Marigolds, and German Wallflowers, which come mostly double and semidouble, to flower in mild winters and the succeeding spring. Most of the above should be sown in the beginning of April, and a batch of them are a good resource to fall back on when a vacancy occurs.

I have taken up so much space that I must be satisfied in thus referring to some of the best annuals for ornamenting the flower garden, leaving those for the greenhouse for some other opportunity. The article, written by snatches, has many shortcomings; but I shall be glad, if by its perusal some of our enthusiastic gardeners in small places receive any hints as to how certain annuals may be best used for definite purposes. In general, when sown on the ground the plants are left far too thick.

R. FISH.

EARLY ARCHERFIELD MUSCAT.

I FORWARD for your inspection (April 24th) a sample of this Grape, which I think you will find to be quite ripe and fit for table. It is cut from a Vine which, as Dr. Hogg saw, has been forced under the following disadvantageous circumstances.

On the 12th of November I put a bed of warm leaves on the border of a Black Hamburgh-house, preparatory to its being started for the supply of Grapes about this time. The plant of Early Muscat from which the sample sent is cut, is growing in the house next to this early Hamburgh-house. Being anxious to put its early qualities to the test by trying it against the Hamburgh, I removed a pane of glass from the division which separates the two houses, and introduced the rod of the Muscat through the opening. This was done contemporaneous with putting the hot leaves on the Hamburgh-border both out and inside the house. The Muscat-house, in the border of which the roots of the Muscat had to act its part against the Hamburghs, was kept open at both top and bottom, as I did not want to start it till nearly two months after the Hamburgh-house. To prevent the cold current of air from acting more immediately on the stock of the Early Muscat, I wrapped a hayband round it; but in all other respects the house and border in which its roots are, remained as cool as it could be kept till the 31st of December, when the house was shut up and warm leaves applied, the same as was done in the case of the Hamburgh-house on the 12th of the previous month; so that in the matter of heat at the root the Hamburghs had about seven weeks of an advantage over the Muscat.

On the 24th November the Hamburghs had fire heat applied, while the house in which the roots of the Early Muscat were had no fire heat till the 20th January. Under these circumstances the race has been run. On March the 23rd the first faint sign of colouring was discovered in the Black Hamburghs, and on the 30th of March I have the following entry in my diary:—"Noticed Early Muscat changing soft and yellow." The Hamburghs are now fit for table, and the first will be cut on the 28th April, while the Muscats are as the sample sent, and which I send for your opinion as to ripeness. I have no hesitation in saying that this variety of Muscat will force as well and as early as the Black Hamburgh.

I may state that it is my intention to send a sample to the Fruit Committee which is to meet on the 5th of May. Probably I may send two bunches; and if your acute correspondent and able pomologist Mr. Rivers, or any other whose opinion is of value, could be present it would be gratifying, as I am not aware that in the ordinary course of forcing, Muscat Grapes of any variety were seen so ripe at so early a season.—D. THOMSON, *Archerfield Gardens*.

[The specimens to which Mr. Thomson refers were received on the 25th of April, and were perfectly ripe examples of a pure form of Muscat of Alexandria.]

THE AURICULA IN 1863.

HAVING received several communications publicly and privately relative to my favourite flower, I must take this medium of answering my correspondents, while at the same time I am enabled to have a chat on our prospects with regard to it.

To our two great Societies we Auricula-growers are much indebted for the stimulus that has been given to their growth, the results of which are abundantly evident in the increased number of exhibitors and the better quality of the plants produced at the spring shows. This applies especially to amateurs; Mr. Turner still holding the place of solitary grandeur and dignity as the only exhibitor amongst nurserymen. When we find that in one year only the number of amateurs exhibiting has been more than doubled; that plants which two years ago might have received a first prize are now to be found nowhere; and that other flower-lovers are evidently preparing for the battle, we may assuredly congratulate ourselves on the progress that is being made. Nor is this all. Some of the most experienced plant-growers I have seen lingering over the collections exhibited, and expressing their unqualified approbation; while ladies, to whom the flower has been a stranger, have so stopped to gaze at the exquisite beauty and novelty of the flowers, that it has oftentimes obstructed the thoroughfare—no difficult matter in these days of distended garments—not that I think at first it is a popular flower with the gentler sex; there is not, perhaps, enough of that gracefulness of appearance which they ever look for as a *sine quâ non* in Flora's domain, but it is one that is sure to win upon them; their neatness and refinement appealing to their love of all that is elegant, and they become after a while its most enthusiastic devotees.

The demand for the Auricula has so greatly increased that neither at Slough, Falkirk, nor in Lancashire, has it been possible to obtain plants of any size; for the Auricula is not a plant that can be propagated as one likes, you must bide its own time. All these circumstances combined tend to make me believe that we are on the eve of seeing the old days of poor John Dixon revived; and that in and around our metropolis Auricula-growers will soon be as numerous as they used to be in "days when I was young," and "The Horns," Kennington, used to be the scene of many a pleasant meeting.

The opinion that I ventured to express, and for which some northern growers were almost prepared to give me Lynch law—that a National Auricula Show would never be again held, is, I think, likely to be more near the fact than our northern friends believed. They this week hold one called such; and although their rules have been somewhat modified, and three-legged Manx Auriculas are not to be exhibited, yet few if any of the really southern growers will venture so far north, or, indeed, as a general rule, would they be able to exhibit at a time so far advanced as the last day of April: and hence I imagine the Show will be to all intents and purposes a northern one; but I hope and believe that ere long we shall be enabled to see a southern or metropolitan exhibition. There is already a South London Auricula Society, where the flowers are exhibited without

any charge and without any money prize, solely for the purpose of making the flower more popular. This may very well be enlarged by-and-by; and I am quite sanguine as to the practicability before long of attempting something of the sort.

"What has become of the Alford Auriculas?" In answer to numerous inquiries on this point I may say that the whole collection has passed into the hands of Mr. Charles Turner, of the Slough Nursery. My late and ever-to-be-lamented friend possessed the most varied if not the most extensive collection of any amateur in England; and, indeed, I hardly suppose that in the whole kingdom there was one which combined so many varieties. These, added to Mr. Turner's already noble "stud," will make his finest collection in the world. As I know the circumstances of the purchase I may just say that it was made without the smallest hesitation; the terms proposed by Mr. Turner being such as his liberal mind suggested as a fair value, and such as the representatives of my dear friend felt few but Mr. Turner would have made. And now those pets over which he had spent many a pleasant hour have changed their home, and he who was looking on to see their opening beauties has left us for ever! Few Auricula-growers who knew him but will, in looking over their stock, think of him. Well indeed will it be for us if, like him, we have thoughts such as he had of higher and better things.

"Can any better frame than that described in the *Cottage Gardener's Dictionary* as Dr. Horner's be recommended for them?" Yes, most decidedly. The very best frame that Auriculas can be grown in is one planned by my friend the Rev. J. Bramhall, Mr. Jeans's brother-in-law, fully described and figured in either the *Florist* or *Gossip for the Garden*; while Mr. Jeans's own notion of an Auricula-frame is given in the *Florist* for 1861, page 273. My own opinion and experience, however, are in favour of growing them in common garden frames, taking care that the glass is large, so as to prevent drip, and then to have an Auricula-house for blooming them in, such as I myself described in the *Florist* for 1860. Since that time I have had one made for myself; it is now full, and a prettier sight in the way of

pered by exposure to the air, I consider nearly as good for them as a gentle summer shower; but by all means let them have all the air possible.

"Where can good plants of the leading kinds be obtained?" Happily the demand for them has so increased, that this becomes a difficult question to answer. Mr. Turner has made a large addition of nearly five hundred plants to his stock, and as many of them are, doubtless, such as he has already, plants may be obtained from him. Mr. Lightbody, of Falkirk, has also a very fine collection, and there are other growers about there. Messrs. Holland & Bayley, of Chadderton, near Manchester, can, I believe, execute orders for some kinds, although, unfortunately, I could not obtain what I wanted from them; but I would advise all who wish to purchase to be sharp about it; it will be next to impossible to obtain plants by-and-by. Where persons are intending to commence their growth, our advice is to procure some of the cheaper kinds at first, and then when one finds that he can manage them, to go on by degrees to the more expensive sorts.

I have thus run through most of the points on which my opinion has been asked, and cannot forbear saying that I hope no one will be deterred from growing them through any supposed difficulty of culture. They require care, but not so much as Carnations and Picotees, and some other flowers. The difficulties have been greatly exaggerated, owing, I think, in a great measure, to the nasty messes that used to be considered necessary to grow them in. Attention to cleanliness and good wholesome food will do as much for them as these will for ourselves, while over-excitement will act injuriously on them as well as on us. Nor, again, are they so expensive as some would suppose. You may, of course, give high prices, but then if you wish to part with them, you can obtain the same. There are kinds such as Maria, Lyeurgus, George Lightbody, &c., which will command their price for years to come, while the commonest sorts growers for sale will always be glad to purchase. I might, had I been so disposed, have over and over again sold mine, and that at good prices. This can be said of few florists' flowers. Tulips are quoted at high prices, but to sell them is another matter. Altogether, taking them in their various aspects, considering their extreme beauty, the comparative scarceness of good collections, and their success commercially (if one may allow such a mean notion to enter into the growth of flowers), I still hold by my first love, and after five and twenty years of constant affection, maintain that no florists' flower is more worthy of general cultivation than THE AURICULA.—D., Deal.

flowers I would not desire to see. Being placed on a level with the sight, the plants can be seen without the trouble of stooping over them. The front sashes can be drawn up so as to give air without allowing the cold wind to blow upon the plants; and if care be given to ventilation and shading, they may remain in this blooming-house during the summer. It may be, perhaps, objected that this is only suitable for a large collection; but if the house be made small at first, it can always be added to.

"Will it hurt Auriculas to let them have gentle summer showers?" My own practice is never to allow them to get rain, not that I think that gentle rain would hurt them, but I consider it to be safer to lay down this rule, called out so much as I necessarily am by professional duty, that my frames should always be down on the least approach of rain. People are such bad judges of what a shower is that I cannot trust to the judgment of others, and by this means I preserve my stock from being saturated with heavy rains. Were I at home, and could run out and cover them when they had had enough, it would be a different thing. But careful watering with rain water when it is to be had, or, at any rate, with water that has been tem-

INVITATION TO MR. ROBSON.

I HAVE amused myself for some weeks past in writing articles in reply to your contributors. It is now time to finish the argument and unmask myself, although to a large portion of your readers I feel it is no unmasking. Mr. Robson persists in referring to old recollections. All he says is, doubtless, true enough, and his friend when he "shook his head," was also truthful. The fact is, he had not discovered the modern simple method of growing Peach and Nectarine trees in pots. But why do I say modern? Loudon tells us in the "Gardeners' Magazine," that Peach trees in pots were grown for twenty years with success by merely giving them surface-dressings. The thing is not new, but the method is simplified and systematised, if such a grand word may be applied to a very facile mode of culture.

To end this discussion, which has given me great amusement—for I am always amused with platitudes advanced with sober seriousness; I fear it is the remains of a love of mischief which when a boy I was famous for—I hereby invite Mr. Robson to come and see me, and my trees, and my houses, and my various "dodges" which I carry on from year to year, and which I hope to do till the "must-be" comes. I shall be happy to receive him with a cheerful welcome, and show him Peaches and other trees in pots standing on a hard clay floor—fed merely, and amply fed, by surface-dressings; others planted out; others on a loose surface to root in; in short, I will show him all that I have. The trees are now full of young fruit not yet thinned, with the exception of the Apricots, of which many thousands have been consigned to tarts. He should come now—it is but a day's journey—and again in August, and then we can taste and argue about flavour just as two old gentlemen should do.

With regard to the flavour of Gooseberries, I have Mr. Robson "on the hip." No Lancashire Gooseberry or Gooseberry in Lancashire, and I have tasted many, ever equalled a Red Champagne or Warrington Red grown in the south of England, leaving the White Fig Gooseberry and some others out of the question.

If Mr. Robson will not come to see me I shall say he is a firm-minded old gentleman, who, "if convinced against his will, will be," &c. (*vide* "Hudibras"); but I trust he will favour me with a visit, all I ask is a day or two's notice. The Harlow station is the most convenient for my house.—THOS. RIVERS.

ADIANTUM MACROPHYLLUM.

EVEN at the present time, possessed as we are of beautiful Ferns of the *Pteris tricolor*, *argyræa*, and *albo-lineata* stamp, I think there are few who will feel disposed to differ from me as to the beauty of the fronds of really lovely hue of the old Jamaica Fern introduced some seventy or eighty years ago—the *Adiantum macrophyllum*.

Generally, and save when in a small pot, I have been in the habit of considering this Fern difficult of culture, a rather misfitted subject, acknowledging very reluctantly the rule of those of the blue apron; and yet it will under some, and those the most simple ways of treatment, adapt itself to the wishes of the cultivator.

I commence by supposing that the operator has a thriving young plant tolerably well established in a 48, or, better still, 32-sized pot, say in February; the fronds of last season's growth are decaying. I would take this plant, and giving it a shift into a 24-sized pot, place it upon an elevated pot, slate, or stage, near the cooler end of the stove, moderately supplying it with water. It may remain in this position about a month; when, if from the necessities of the stove plants generally, in the same compartment, the heat is not then advanced about 10°, the *Adiantum* should be removed so as to obtain that temperature. Probably about this time young fronds will have pushed. If there should be from eight to twelve with the pinnae expanded in part, then cut away the whole of the old fronds of last season. Divested of its old fronds it will make a stronger start, and must now receive a slight increase of temperature. I would let it remain in this situation about another month, gradually watering it more frequently.

The above treatment would bring it on into April, when the days are long enough for a further advance of heat. I would now, in a shady situation, give it 60° by night, from 75° to 80° by day; and an essential point is that the pots be so plunged in moss around the pipes, or in a gentle hotbed, as to insure the roots being in a temperature of 70°. From thenceforward, until the plant has done growing, deluge it well with water, and gently. The influences of these combined inducements will show themselves in the form of numerous fronds arising from the plant.

Thus continue each season; and in the following February I would give the plant a liberal shift into, say, a 12-sized pot, giving it a six-inch the following year, when it should be a fine specimen compared with what we meet with generally—say a yard in diameter, and having fronds all fresh in their beauty, and attaining some 14 inches long, such a pot averaging some seventy of such fronds.

Care must be taken that no particles of water be allowed to stand on the fronds; otherwise they very quickly fade, and at times even rot or fog-off.

The soil it appears to like best I compound of some good rubbly charcoal, not pounded too small; rough little squares of a fibry sandy peat, having the weightier part sifted out; some good fibrous loam, with a fair proportion of silver sand, and added to these a fair proportion of small potsherds.

In potting I half fill the pot with charcoal and potsherds, and intermixed with these a few of the finer lumps of fibry peat. The latter should be placed in carefully, packing each as closely as possible without breaking them. Then, before the old ball is placed upon these, take off all old substances where practicable without injuring the roots; and fill up with the mixture generally, taking care to finish off at the surface with some of the finer material.—W. EARLEY, *Digswell*.

EARLY BLOOMING OF THE HAWTHORN.—As a proof of the forwardness of the season, I beg to state that yesterday, April

25th, I gathered a piece of Hawthorn with the blossoms fully expanded from a hedge near this village. I have once gathered it on the 27th of April, but I never before saw it so forward as it is this year.—ROBERT S. STEDMAN, *Sharnbrook, near Bedford*.

HARDY ANNUALS.

IN THE JOURNAL OF HORTICULTURE of 31st March I have read a list of garden annuals, at the foot of which is a suggestion for other ideas to be thrown out on the subject. The following I know to be good showy things in that way, and such as may be grown by any one.—B. H.

<i>Athanasia annua</i> , 1 ft., yellow.	<i>Lasthenia californica</i> , 1 ft., yellow.
<i>Bartonia aurea</i> , 1 ft., yellow.	<i>Lavatera</i> , red and white, 2 ft.
<i>Brachycome iberidifolia</i> , 1 ft., greyish blue.	<i>Leptosiphon</i> , various, 1 ft.
<i>Clarkia pulchella flore pleno</i> , 1 ft., rosy purple.	<i>Linum grandiflorum coccineum</i> , 1 ft., crimson.
<i>Chrysanthemum Burridgeanum</i> , 2 ft. white and crimson.	<i>Lupinus</i> , various, 2 ft.
<i>Calliopsis bicolor</i> , 2 ft., yellow and brown.	<i>Malope grandiflora</i> , 2 ft., crimson.
<i>C. Drummondii</i> , 1 ft., yellow and brown.	<i>Nasturtium</i> , dwarfs—Cattell's crimson; Tom Thumb scarlet, ditto yellow, ditto Beauty; <i>Nasturtium Dwarf Spotted</i> .
<i>C. coronata</i> , 1½ ft.	<i>Nemophila insignis</i> , 6 in., blue.
<i>Centranthus macrosiphon nanus</i> , 1 ft., pink.	<i>Oxyura chrysanthemoides</i> , 9 in., yellow.
<i>Collinsia bicolor</i> , 1 ft., lilac and white.	<i>Petunia</i> , mixed.
<i>Convolvulus tricolor splendens</i> , 1 ft., purple.	<i>Phlox Drummondii</i> , mixed.
<i>Dianthus chinensis</i> , 9 in., mixed reds.	<i>Poppy</i> , Dwarf French, 2 ft., mixed.
<i>D. chinensis Hedewigi</i> , 9 in., mixed reds.	<i>Saponaria calabrica</i> , 1 ft., pink.
<i>Erysimum Peroffkianum</i> , 1 ft., orange.	<i>Scholaria californica</i> , 6 in., yellow.
<i>E. Arkanianum</i> , 1 ft., yellow.	<i>Schizanthus</i> , mixed, 1½ ft.
<i>Feverfew</i> , double, 1½ ft., white.	<i>Silene pendula</i> , 9 in., pink.
<i>Godetia rubicunda</i> , 2 ft., purple.	<i>Sphenogyne speciosa</i> , 6 in., yellow.
<i>G. Schamini</i> , 2 ft., white.	<i>Tropaeolum Caroline Schmidt</i> , scarlet.
<i>Helichrysum compositum maximum</i> , 2 ft., mixed.	<i>T. Brilliant</i> , scarlet.
<i>Iberis umbellata sanguinea</i> , 9 in., crimson.	<i>T. Schultzi</i> , scarlet.
<i>I. coronaria</i> , 9 in., white.	<i>T. Barkeri</i> , mixed.
<i>Ipomæa Burridgi</i> , rosy crimson.	<i>T. Scheurmannianum</i> , buff and brown.
<i>I. atro-violacea</i> , purple. (Climbers).	<i>T. Scheurmannianum carneum</i> , buff and red.
	<i>T. Lauderii</i> .
	<i>T. canariense</i> .
	<i>Viscaria</i> , mixed, 9 in.
	<i>Zinnia elegans</i> , 1½ ft. mixed.

ROSES IN THE SUBURBS.

IN continuation of my former papers for suburban Rose-growers, I shall proceed to give the results of the past winter with me as exhibited in the behaviour of several favourite kinds. Of course they may not correspond with the observations of others; but it is only by the comparison of various experiences that reliable data can be established. From October last to the present time we have enjoyed a singular immunity from severe or continued frosts; yet we have not been without two or three sharp spells, which have left their effects upon my limited rosery. This has been particularly the case with small plants on their own roots turned out of pots during the last summer, several of which have succumbed to the influence of cold or damp. Damp in the early spring months is extremely fatal to young plants, which dwindle and go off between "wind and water," as the gardeners term it; and the method by which I hoped to counteract the enemy (by placing a mulch of charcoal round the collar), has not in all cases proved successful. H.P.'s *Anna de Diesbach*, *Duc de Cazes*, *Princesse Mathilde*, and *Eugène Appert* on their own roots are among the sufferers; the first-named, especially, seems really delicate in that form; the others, though usually considered hardy, have followed in its wake. Perhaps when the last frosts occurred they were too forward and full of sap. Upon the *Manetti* the case has been quite different with the same varieties, except *Diesbach*. They are flourishing and even in bud: hence I conclude that for amateurs, whose space only allows them to cultivate limited collections, the *Manetti* is the most advantageous stock. B.'s *G. Peabody*, *Aurore du Guide*, *Comice de Seine et Marne*, *George Cuvier*, and *Madame Helfenbeim* (similar kind of plants to the H.P.'s), are also among the departed; as well as *Teas*, *Mélanie Oger*, *Goubault*, *Viscomtesse de Cazes*; *Noisette*, *America*; and *C. Mrs. Bosanquet*. These young plants appear to require more bottom heat than is natural to the ground in spring to start them at that period. I get on very unsatisfactorily with those beautiful *Roses General Washington* and *Madame Furtado*. They neither grow nor open well, and I fear will not do for us townsmen.

What will be the consequence of a continuance of the present

weather upon the Rose shows I am at a loss to imagine. In my little plot there are upwards of a dozen varieties of established plants in full bud, to be cut off, I fear, by late frosts, or to be worthless from premature development. Their enemies also keep pace with them. The pernicious black grub is in its old haunts, destroying the embryo flower, and the aphid is becoming rampant. I can, however, effectually keep it down. I shall name the kinds so forward here, as they may be considered early varieties, and worthy of notice on that account under favourable circumstances. H.P.'s, Anna Alexieff, Jules Margottin, Victor Verdier, Madame Domage, Madame de Cambacères, Triomphe de Paris, Triomphe des Beaux Arts, Général Jacqueminot, Pius IX., Reine des Violettes, Duchess of Norfolk, Senateur Vaisee; and of 1862, Monte Christo and Madame C. Joigneaux; Bourbon, Catherine Guillot; and of Teas, Gloire de Dijon and Madame Willermoz. The latter, on its own roots, seems very hardy and robust, having withstood the same adverse conditions under which so many others have failed. Of 1862, Madame C. Wood, Notre Dame de Fourvières, Souvenir de Comte Cavour, Charles Lefebvre, Maréchal Vaillant, F. Lacharme, and Louise Darzins are all very vigorous and forward; and I think, as I have said before, that 1862 will have given us an unusual number of superior Roses. Perhaps the plan I have adopted of hanging a breadth of tanned netting, about 6 feet high, round the garden may have had something to do with their early development. Roses like plenty of air, but cold draughts do not agree with them better than with the human species.

Knowing how eagerly scraps of information respecting novelties are sought after by enthusiastic cultivators, the following remarks upon what I have seen of them at Messrs. Frasers', Wm. Paul's, and Paul & Son's, may not be without interest. Your able contributor, "D., of Deal," gave us an interesting descriptive list of the forthcoming competitors for popular approval in a number of your Journal towards the close of last year. Of course the produce of the forcing-house is no criterion of ultimate results; still, if a variety does well there, it may be assumed likely to prove a success. The most promising of those I have seen are B., Louise Margottin, a beautiful kind of a delicate and desirable colour, somewhat in the style of Louise Odier, as most of new Bourbons worth anything are; H.P.'s, Jean Goujon, Baron de Rothschild, Le Rhone, Madame Wm. Paul (a purplish-crimson flower, very double, and appears to be an acquisition in its line), Madame C. Kod, not particularly novel, and Duc d'Anjou.

It is somewhat surprising that Rose-amateurs do not more frequently avail themselves of the floral treats within their reach. The first-rate nurseries are always cheerfully opened to respectable visitors, who will usually find plenty of choice varieties, to say nothing of other objects of interest, in bloom in the forcing-houses at this time of year; and those who wish to extend or complete their collections will now have the choice of the frames for plants in pots to turn out during the month. A word of advice respecting the best method of doing this. Be sure the soil is light enough. The young roots require some free and open, though rich stuff, to deal with the first season, and it is a great assistance towards establishing them, to protect and shade the plants by means of a large flower-pot, or something of the kind turned over them for a few days, leaving it off gradually, first by day, and then altogether.—W. D. PRIOR, *Homerton*.

THE PANSY.

I CANNOT remember so far back as can your correspondent, "DAHL, Manchester," but I knew Mr. Thomson well, having been a neighbour of his some years ago. I regret to tell "DAHL," that Mr. Thomson has been dead about six years. I have never seen since I left Iver any collection of Pansies that equalled Mr. Thomson's. If I send for seed saved from first-rate flowers I never raise a seedling worth saving.—GEO. HOLMES, *Woodchester*.

ENCOURAGEMENT TO PLANTERS.—The late Sir Watkin Williams Wynn planted between 1814 and 1819, on the mountainous lands in the vicinity of Llangollen, situated from 1200 to 1400 feet above the level of the sea, 80,000 Oaks, 63,000 Spanish Chestnuts, 102,000 Spruce Firs, 110,000 Scotch Firs, 90,000 Larch, 30,000 Wych Elm, 35,000 Mountain Elm, 80,000 Ash, and 40,000 Sycamores. The profits arising from the thinning of these trees have already far more than paid for the expense of

planting and fencing; while the crop remaining is valued to pay a much higher rent for the land, from the period of planting to final clearing away, than could have been got for it from any other purpose to which it could have been applied.—(*Dublin Agricultural Review*.)

FLUES VERSUS HOT-WATER PIPES.

I WILL call your attention to that part of "E.'s" article, page 211, which Mr. J. Robson advocates. Unluckily "E." has omitted giving the length of the flue, the height of chimnies, size of fireplace, &c., and the last two would make a great hole in 50s.; for want of which information, I hope he will not take it amiss if I try to show the actual cost per yard, leaving the fireplace and chimnies for the present.

Now, the sides are formed of bricks laid flat, 12 inches deep inside. These would require sixteen each. Again, he fails to inform us as to what the bottom consists of. May I, therefore, allow sixteen bricks for the surface of the bottom? and as it will require to rise as it extends, we will say two layers, which makes thirty-two for the bottom. We now want three firetiles 18 inches by 12, which will be 10d. each, making with the cost of the bricks a total of *3s. 6d. per yard.

For my part, in the formation of a small flue, I would have tiles put on two bricks, placed edgewise so as to allow the air to circulate under the flue, for a bottom; bricks placed edgewise for the sides, as the flue will then give out more heat at the sides than in "E.'s" plan, who has nearly all his heat from the top. I should then require firetiles 12 inches by 12, at 6d. each, which would make a total of *2s. 6d. per yard.

So much for flues; and I will now proceed to investigate the price per yard of water-pipes to heat a house a little larger than "E.'s." For this purpose I would choose three-inch rain-water pipe, which I can procure easily at 1s. per yard; the return-pipe being reckoned, makes it 2s., and the average cost per yard for joining the pipes together with hemp and Portland cement, 3d., in all *2s. 3d., leaving 1s. 3d. per yard in my favour as compared with "E.'s." Now (for materials, labour of setting the boiler, and building chimney I shall cancel, by the building of fireplace and chimnies in "E.'s" case), there only remains the boiler, a small one, which may be had for much or little. I will only add that I can obtain more heat in less time, with less trouble in cleaning, and a great saving in fuel. These things speak for themselves.

The Polmaise system was, and is, I dare say still, in favour with Professor Lindley. I am very much surprised it did not meet with a better reception after all that has been spoken in its favour. The best to work that I ever saw is at Messrs. Lanes' Nurseries, Berkhamstead, which is the same one so minutely described some few years since in a contemporary. They omitted, though, to state the enormous quantity of fuel consumed by it in one day, compared to what would have been required had there been hot-water apparatus fixed instead.

By-the-by, I see no reason why I should not try to correct a common error made in fixing hot-water pipes. Many people fix their flow-pipe on a dead level, allowing the return to sink gradually from the extremity to the bottom of the boiler. Now, we know that if a pipe leaves the summit of the boiler, rises perpendicularly, say for 20 feet, and sinks at once to the bottom of the same, we obtain a superlative circulation; but the more the pipes decline to the horizontal position, the less rapid the circulation, and the less heat do we obtain. Now, why do we not have the pipes to rise at an angle, say of 10°? Simply because, if carried to any distance, the pressure on the bottom of the boiler and flow-pipe is so great, owing to the height of the water, that something must give way unless everything is made proportionately strong. I, therefore, advocate, a rise, according to the distance the pipe is required to go, of for twenty yards 1 inch in three yards, for forty yards half an inch in three yards, and for a hundred yards three-eighths of an inch. By so doing you obtain a ready circulation, and avoid misfortunes similar to Mr. J. Robson's (see page 292.)

I recollect M. Louis Van Houtte, nurseryman, Ghent, relating an incident attending the fixing of a hot-water apparatus in a very large conservatory at St. Petersburg. He received a letter requesting him to go there at once, as the severe weather was coming on, but they could not get the water to circulate, being obliged to pour the water in at the boiler end, and actually pump it out at the other, so as to keep the frost out! Being

* These prices are the lowest I can get the work done for in the country.

unable to leave his business, and suspecting the cause, he at once wrote to them to make the flow-pipe rise so much in such a distance, which when done was found to answer better than a dozen pumps.

Might I ask "E." what it would cost to heat with a flue a house 60 feet long by 18 broad? Also, the quantity of fuel consumed in a week, and the heat he could obtain in a given time? If not too low in cost, I will try to have hot-water pipes to heat the same for less than four times his expenditure.—J. E. L., JUNR.

HYBRIDISING RHODODENDRONS AND FUCHSIAS.

I BEG to thank your correspondent, H. H. Glenville, in your Number, April 7th, for having corrected me in replying to an inquiry the preceding week on Rhododendron culture. At the same time I think I have been misunderstood in the views I took on hybridising, and possibly when I further explain the matter our opinions on the subject may be found both alike.

I stated that seedlings from hybrids having some affinity to each other, were more likely to do well than when the cross was between parents differing widely from each other, and I cited Fuchsias as an instance of failure; but in doing this I by no means denied the likelihood of success between such varieties as Clio and Queen of Hanover, for although I am not acquainted with one of them, I conclude they are fashionable varieties of the greenhouse class. Cross-breeding as it is called is a misnomer here, the relationship between the varieties rendering such a proceeding comparatively easy; but try a cross between two distinct species, as *Fuchsia corymbiflora* and *F. microphylla*, and if that succeed then there is cross-breeding in the full sense of the word. It was extreme crosses like this that I thought would not answer in Rhododendrons—say, for instance, a cross between *R. catawbiense* and *R. ferrugineum*, or any other widely different species. These were the crosses that I said were not likely to furnish a useful progeny. I am glad, however, that Mr. Cox has given us his experience on the Sikkim kinds. No one that I am acquainted with is better qualified, and I hope he will favour us with other notices on plants cultivated at Redleaf. No doubt in a short time the Rhododendrons there as well as elsewhere will be magnificent. I am glad to hear of their doing so well in Ireland. There, are, however, some places where they will not succeed unless earth suitable for them be obtained elsewhere, and that sometimes at long distances, and even there they can hardly be said to be so much at home as when in a soil natural to the place.—J. R.

PETUNIAS FROM NEW YORK.

A KIND friend to horticulture, whose name is appended below, having sent a package of plants to our worthy coadjutor, Mr. Beaton, who, all lovers of gardening will be sorry to hear, is suffering from a long continued illness, the plants have been kindly consigned to my care; and I can only thus publicly convey my thanks to the donor, and append his remarks on the plants, which our worthy transatlantic cousin gives in a humorous style every way becoming the profession he patronises.

Although the plants sent are named after individuals who figure prominently before both the Old and New Worlds, and, consequently, call forth political feelings of a party nature foreign to the peace-loving profession our periodical so truly advocates, it must, nevertheless, be conceded, that amidst all the tumult of party feeling, irritated now and then by events taking place elsewhere, our New York friend writes with a tone of humorous playfulness, and does honour to an antagonist of his country, which we are not always disposed to do at home. Whether his prediction of the future governors of the far west be true or not, the absence of asperity in a letter (half gossiping, perhaps intended), itself speaks of the candour of the writer, who amidst the strife of civil warfare still finds time to follow out the more humanising calling he is evidently so great an ornament of. It will be best to give his own introduction to the Petunias, which, as will be seen, were in a letter intended for Mr. Beaton, who had some months back given a favourable opinion of them, from a plate that had been sent him. Writing from New York, our correspondent says—

"I am certainly highly gratified by your complimentary notice of the plate of my Petunias, which I trust will turn out

all that you desire. I have now great pleasure in attending to your request, by sending you the two honourable gentlemen, the 'Presidents,' and also some of our military celebrities, by which you will readily perceive that we are at present a warlike people.

"No. 1. *Abe Lincoln*, President of these United States.

"No. 2. *Jeff. Davis*, present President of the Southern Confederacy.

"No. 3. *Gen. McClellan*, our next President that is to be.

"No. 4. *Little Mac*. We will presume he is the son of the General, further comment is unnecessary in his behalf.

"No. 5. *The Zouave*. This is not the original, as he has nearly disappeared from constitutional debility. Having sprung on the paternal side from rather a slender race (*Nierembergia intermedia*), still his blood circulates in the veins of all this strain of Petunias.

"Now, my dear Sir, I have said about enough, and complied with your request to the best of my abilities—put both Presidents into your hands, with the apparent succession and his supporters, which you can harmonise at your leisure in your own garden, on the banks of the Thames, without the trouble of a disagreeable passage across the Atlantic. I sincerely trust they may all reach you alive, that you may be enabled at some future day to report progress how they succeed under your benign influence.

"The two McClellans are double flowers; the elder very double, the junior half-and-half (that would do as a sign for the 'Hand and Flower' at Hammersmith). The others are such as you see on the plate.

"I have put in the package two of our native Ferns, *Lygodium palmatum*, and *Asplenium rhizophyllum*, as I know you are fond of such not-very-plenty things.

"I will shortly have the pleasure of calling to your notice a new yellow Rose, a seedling off *Tea Saffrano*, much the same in habit of growth, and equally free in flowering, only a little more double, of a deep canary colour, and strongly Tea-scented. This is altogether the best yellow Tea Rose that I have seen.

"I will send you a plate when it is figured. Trusting this may reach you in the enjoyment of good health, and fully prepared for the season of the grand exhibitions,

"Believe me, my dear Sir,

"Yours very truly,

"ISAAC BUCHANAN."

Our worthy correspondent will, no doubt, be pleased to hear that the plants came safely to hand; and although one or two of them have succumbed to an ordeal so trying to small, half-succulent plants like *Petunia*, in thumb-pots, still by the duplicates sent all the kinds are alive and doing well, as likewise are the two Ferns; and it is only fair to bear this public testimony of the admirable packing by which a small case of plants so young and tender have endured the long confinement of a transatlantic voyage, and some delay after reaching England. Of their merits, it is, of course, too early yet to venture any opinion, but I will at a future occasion do so, and I have no doubt but they fully bear out all that has been said about them. At the same time our New York friend, if he has not been in England lately, must bear in mind that improvements have been going on with the *Petunia* here as well as with him, that the varieties held in high repute three or four years ago, have been succeeded by others much their superiors, the double ones especially being much improved. Nevertheless, due justice shall be done to our far-travelled specimens, and we hope the warlike feeling which has called into existence the names given to the innocent flowers noted above, may have entirely subsided ere the report of their successful flowering here has been wafted across the Atlantic. Their merits, nevertheless, shall be duly recorded; and I believe the readers of *THE JOURNAL OF HORTICULTURE* will be exceedingly glad of communications from the other side of the water making their appearance from time to time in its pages. The present is, therefore, we hope not the last from the party who has forwarded the above communication together with the plants he has sent.—J. ROBSON.

THE MERITS OF AN ORCHARD-HOUSE.

THE discussion as to the value of orchard-houses has been renewed lately, and a good deal has been said in their disparagement by those who think unfavourably of them in a remunerative point of view. To try the question on this issue alone might, probably, turn the scale against them, as there are, perhaps, not many (Mr. Rivers and a few others excepted) who are skillful enough to have year after year their trees in full bearing.

I know I am repeating what has been stated by many of your correspondents when I say that the real value of the orchard-house to the cultivator of limited means is the opportunity thus afforded him of growing a greater number of different kinds of fruit trees than he otherwise could have room for, the protection against spring frosts, and the facility with which he is enabled to place the different sorts in the soil most suitable to their various requirements.

I have a lean-to orchard-house 15 feet by 8, without artificial heat, and it is thus filled—viz., two Figs in the border, trained to the back wall, three Vines in the border in front; three Peaches, two Nectarines, five Plums, and one Mulberry in pots. The Figs are Angélique and Brown Turkey, and have about a dozen and a half of fruit on each, already of good size, which will, no doubt, ripen well. Only two of my Vines are in bearing, the other being too young; the kinds are Purple Fountainbleau and Muscat St. Laurent, which bear and ripen admirably, the former especially is a most prolific kind, and the latter has a true Muscat flavour. Contrary to the experience of "DUCKWING" in your paper of the 14th ult., my Peaches and Nectarines are, upon the whole, this year, a failure. Although they blossomed most beautifully, one tree, the Shanghai, is an exception, and is well studded with fruit fairly set. The Plums, however, are and have always been with me a decided success.

My garden soil is of a loose friable nature, and though Plums generally blossom profusely they very seldom yield a crop. I, however, fill my Plum pots with soil, half of which is the strongest clay I can get, mixed with garden soil for the other half. It generally cakes pretty stiff, and the fruit set beautifully; I have two Reine Claude de Bayay (a most exquisite fruit), one Jeffer-

son, one Coe's Golden Drop, and one Green Gage, with as much fruit set as they can ripen, and now of the size of small peas. Let "DUCKWING" try this, and I think he will succeed with Plums.

The greatest enemy to be contended with is a small caterpillar, which begins to make its nest in the leaf as soon as it begins to unfold, and to this it attaches the nearest embryo fruit, which it soon eats into and destroys. The trees require to be daily gone over by hand for a week or two when the fruit is setting and the worms destroyed.

I have been unsuccessful in cultivating the Mulberry in the open ground, but I have a nice compact tree between 3 and 4 feet high, in a pot, which bears regularly every year. The fruit is hardly developed yet, but appearances indicate from five to six dozen berries—no great quantity certainly, but sufficient to furnish a *bonne bouche* occasionally. I may mention that although the tree has been in bearing for several years it has never yet shown male blossoms, and the fruit is, consequently, seedless.

I had almost omitted to say that I have besides the above, for ornament, two double-blossomed Chinese Peaches, from which I sometimes obtain a few fruit, and a Clematis lanuginosa and C. azurea grandiflora, which prolong the gay appearance of the house now that the fruit-blossom is over.

I certainly sympathise with the genial feelings so well expressed by Mr. Rivers in his communication of the 22nd of March; for, independent of the fruit to which the cultivator looks forward, he has in the spring the finest floral display any greenhouse can furnish, besides many accompaniments of a delightful kind to a lover of nature.—J. F., Haddington.

GARDEN PLANS.

THE accompanying drawings illustrate two designs which have recently been furnished by Mr. J. W. Chapman, of Richmond, Surrey, for Mrs. Millett-Davis, of Garston Lodge, near Liver-

pool. It may be observed of the first, that had there been room this design would have looked well if the circle had been complete.

PLAN. NO. 1.

- 1, 1, &c. Specimen half-standard Roses.
- 2, 2, &c. Beds of dwarf hardy Heaths.
- 3, 3. Beds of Rhododendron hirsutum.
4. Perilla nankinensis, edged with Geranium Golden Chain.
- 5, 5. Geranium Madame Vaucher (white), edged with Verbena Firefly (scarlet).
- 6, 6. Geranium Princess of Prussia (scarlet), edged with Verbena Reine Blanche or Snowflake.

- 7, 7. Petunia Géant des Batailles (purple), edged with Lantana Doris (yellow).
- 8, 8. Calceolaria Aurea floribunda, edged with Verbena Purple King.
- 9, 9. Verbena Fair Maid (mauve), edged with Calceolaria Gem (bronze).
- 10, 10. Lobelia racemosa or erinus grandiflora (blue), edged with Lantana crocea superba (orange).

PLAN NO. 2.

- 1, 1. Specimen *Yucca recurva*.
- 2, 2, &c. Specimen *Andromeda floribunda*.
- 3, 3, &c. Beds of dwarf hardy Heaths.
- 4, 4. Beds of scarlet and white hybrid *Rhododendrons*.
5. Centre of bed *Perilla nankinensis*, second row *Geranium Vivid* (scarlet), outer row *Verbena Mrs. Holford* (white).
- 6, 6. *Verbena Lord Raglan* (scarlet), edged with *Peunia Alba Magna*.

- 7, 7. *Verbena Violacea Superba*, edged with *Calceolaria Yellow Dwarf*.
- 8, 8. *Geranium Golden Chain*, edged with *Heliotrope Etoile de Mar-seilles* or *Napoléon III*.
- 9, 9. *Geranium Bridal Wreath*, edged with *Heliotrope Souvenir d'un Ami*.
- 10, 10. *Stachys lanata* or *Gnaphalium lanatum*, edged with *Geranium Countess* (orange salmon).

KEENS' SEEDLING STRAWBERRY NOT BLOSSOMING.

IN looking over such of my Strawberry-beds as consist of runners of last year's growth, I observe a very marked difference in the percentage of truss-bearing plants. Of Keens' Seedling, not one in a hundred shows sign of a blossom, whilst of Princess Frederick William scarce one per cent. of the plants are barren. Between these two my other sorts range irregularly, but none of them are nearly so profitless as Keens', which is, however, a most abundant bloomer with me in the second year.

All the runners were strong and well rooted, and were planted in their new beds within less than five minutes from the time of their removal. Should I have better success with Keens' as a fruit-bearer during the first year, if I allowed the smaller radicles to dry up before being planted? or would it, perhaps, be preferable to apply root-pruning, and cut off, say, one-third of the roots with the view of forcing the formation of fruit-buds by checking the growth of the plant?

Princess Frederick William and some other sorts are quite a success with me treated as annuals, or rather as biennials, planted of course very thickly.

Liebig's new work on the "Natural Laws of Husbandry," throws some very interesting light upon Clover and other agricultural plants bearing some analogy to the Strawberry in their biennial or perennial character. When reviewing the work, your readers will gladly hear something as to the carrying-out of his theory in gardening practice.—FRUIT-EATER.

[It is difficult to account for the absence of blossom on the popular variety mentioned above, as usually it is the best of all kinds as a general cropper; and if it was treated the same as the other kinds which are flowering well, we can only account for it on the supposition that the runners must have been either extra strong, and, consequently, expended their strength in producing sub-runners, or if very weak and late in planting they had not time to perfect their crowns so as to insure a good bloom in embryo. It is seldom, indeed, that healthy vigour impairs fruitfulness in an herbaceous plant like

the Strawberry, although it often enough does so in a shrub or tree.

We cannot see any particular advantage in cutting the roots; on the contrary, it may do harm. It might be better to layer the runners into pots another season, and plant them out if you be certain the non-flowering arises from over-luxuriance. At all events we would not advise anything being done to check the growth, as with that the formation of healthy flower-buds keeps going on. It is also possible, although it is unlikely, that the situation is not favourable to Keens' Seedling. In many places it is almost impossible to make the British Queen grow, let alone succeed well. Is your bed of Keens' Seedling shaded by trees or buildings, or in any other way less favoured by the character of the ground than the other kinds are? We can hardly suppose the variety to be in any way deteriorated by its long cultivation (some thirty or forty years). In most places it is still the most popular kind grown, and it generally succeeds well.

Your beds of Keens' flowering so abundantly this second year is a proof that the situation suits them, and it also confirms the fact, that extreme luxuriance tends to fruitfulness, as we will readily expect the plants to have been vigorous the season there was no fruit on them. Planting a few runners another season on poorer ground will show if a more retarded growth tends more to fruitfulness; but in many places it is difficult to get them to make growth enough, and even then their blooming is anything but satisfactory?—EDS. J. OF H.]

THE CROPS IN CORNWALL.—All the crops, whether fruit or vegetable, give promise of a very abundant season. The Apple trees are covered with blossom. Peaches are to be seen as large as marbles. Cherries, Plums, Nectarines, &c., all well set. Gooseberries are thick and early, and are selling at half-a-crown per quart. Wheat and other grain look very fine. 276 baskets of Potatoes have this week been sent to London from

Penzance. Onions are in a very flourishing condition. Peas are in blossom; indeed, market-gardeners generally say that if the weather continue fine, there will be as good a season as there has been for many years past.—W. P. JUN.

BARBADOES POTATO.

THERE is a kind of Potato in this part of the country which may, perhaps, be the Barbadoes Potato, which your correspondent "CONSTANT READER" inquires about. It was brought over from California this time last year by a neighbouring farmer, and gave a large return.

The tubers are of two kinds, one red the other white. The largest specimens I saw were about 8 inches long and about 2 broad. The shape round, not flat. The skin is smooth, but the whole tuber is covered over with knobs. It very much resembles a kind of Potato I have seen in the south of France, but vastly exceeds this latter in size. The man who brought it over desired me to plant the sets 2 feet apart, said that it grew very tall and branching, and had very striking blossoms of four different colours; he also represented it as exceedingly prolific. It does not seem to be a very early kind, as all our early kinds are far ahead of it.—Q. Q.

A GOOD BOILER.

As I observe that one of our recognised authorities on gardening matters, Mr. Robson, requests the particulars of a good boiler, it will enable all of us who may be interested in such details (and, perhaps, we are each individually too prone to imagine that whatever succeeds best under our own supervision must be the best of its kind) to arrive at some practical opinion on the point, if Mr. Robson will kindly favour us with his judgment after considering the different plans that may be described. I have made use of most of the different methods of heating, and without saying that my present arrangement is the best, I will describe it and its work, and leave it to Mr. Robson to decide.

The boiler is an upright one by Truss, 2 feet 6 inches high and 1 foot 8 inches in diameter, placed at the end of a lean-to conservatory-house, 27 feet by 10, 11 feet high; 6 feet of the back is wall, the upper 5 feet thin boards with ventilating windows. The main flow and return pipes pass through this house, heating it more than is required, on their way to the upper-terrace house (span, glass all round), which is 12 feet above the level of the boiler. This house is 30 feet long, 10 feet wide, and about 8½ feet high, divided into three—a coach-house, a greenhouse, and stove.

In the stove the pipe heats a propagating-tank of 7 feet long, and on its return makes a circuit in the Cactus end before joining the main flow. The water then descends to the lower level, and before returning to the boiler heats a large open-air tank covered with slates, 8 feet long by 3 feet 6 inches wide, and about 2 feet deep, which can be used for propagating or growing Camellias under tall hand-glasses.

The fire, if attended to properly at half-past ten at night, is still alight at six A.M., and the water in pipes and tanks quite hot. All last summer we only used the cinders and breeze of the house; but in the winter months I have used coke as well—about 1½ chaldron per month. In the lower house the ventilators have been necessarily kept open almost always day and night during the past mild season, or the temperature would have been too high.

The boiler is not a patent, though the pipes are those of Truss & Co., of Gracechurch Street, advertised in your columns; but it is an honest and deserving patent, enabling any gardener or amateur to take out and replace any length of pipe that may be defective, and with the advantage that the whole apparatus may be removed at a moment's notice.

Should Mr. Robson come into my neighbourhood it would afford me much pleasure to show him the whole of my limited arrangements, and to thank him personally for the many hours' gratification and knowledge that I have gained by perusing his articles.

Before sending this off I inquired of my gardener, who, although not a scientific man, has had many years' experience, and he says that our present mode of heating consumes less fuel, and gives less trouble than any of the various modes that he has had under his care; and that if carefully fired and made up at night it will

be alight after eleven or eleven and a half hours.—C. M. MAJOR, *Cromwell House, Duppas Hill Terrace, Croydon.*

[We have read over the statement. There is little doubt of the heating in the circumstances; but the conditions required by Mr. Robson are not given—expense of heating, material, and consumption of fuel for the space to be heated. The only singular thing, and a most capital idea it is, is bringing the return-pipe through a cistern of water out of doors, so as easily to get heated pure water.—EDS. J. OF H.]

CHEAP FLUES.

At page 211 of THE JOURNAL OF HORTICULTURE your correspondent "E." represents that he heated two houses, each 20 feet long and 15 feet wide, by means of a smoke flue at a cost of 50s. A gentleman who saw this statement, and who is erecting a vinery 90 feet long, came to consult me as to the practicability of his heating it at the same rate of cost. I at once told him that I had no idea how it could be done; that all flues I had ever seen had a furnace front and cast-iron bars, and generally a damper, and that flues required foundations—arches, in fact, if in a vinery, for the arrangements for the roots of the Vines to be what they ought to be—and that 50s. would go a very short way in providing the above. That portion of the article appeared very much like an advertisement to the effect "there is nothing like bricks," "E." being a vendor of that very useful commodity.

The matter has, however, now assumed a different aspect when your highly intelligent correspondent, Mr. J. Robson, accepts and puts forth "E.'s" statement with his signature across it; and to prevent misunderstandings with those who have such works in progress I consider that either "E." or Mr. J. Robson should give the full particulars, with the cost of the various items; for I am convinced something has been forgotten in the estimate.

For Mr. J. Robson's information let me say that I took an estimate from a bricklayer for a flue to heat a vinery 110 feet long. The flue was to be along the whole length, and both ends of the house and on arches, so that the Vine roots could run under it. The cost of the place was to be £19 10s., and for that sum I erected a hot-water apparatus, boiler, and everything complete. There are only two rows of pipes along the front and one end. The house is a late vinery, and that extent of pipe is found ample. The apparatus has been up six years, and has not cost sixpence since its erection; whereas the least that could be allowed for cleaning-out the flue would be 5s. annually.—WM. THOMSON.

ENTOMOLOGICAL SOCIETY'S MEETING.

The April Meeting of the Entomological Society was held on the 5th inst., the President, F. Smith, Esq., being in the chair. Valuable donations to the library received from the Royal and Linnæan Societies, the Society of Arts, the Royal Agricultural Society, Dr. Schaum, and Messrs. Saunders, Hewitson, &c., were announced; and Professor Lacordaire, of Liege; Dr. Hagen, of Königsberg; and Dr. Leconte, of New York, were elected honorary members of the Society.

General Sir J. B. Hearsey exhibited a box of handsome Lepidopterous insects belonging to the family Noctuidæ, from India, including several new species.

Mr. G. R. Waterhouse exhibited a new British species of Staphylinidæ, *Aleochara inconspicua*, remarkable for the great length of the terminal joints of the antennæ.

The President made some observations on the economy of the curious parasitic Beetle, *Claviger testaceus*, which he had found in Ants' nests in some numbers near Croydon, and which he had kept alive by offering them sugar dissolved in water upon blotting paper, which they had readily sucked. Specimens had also been found in the nest of the common garden Ant at Folkestone. It was generally in Ants' nests concealed beneath flat stones that these little Beetles were to be found.

Mr. J. Lubbock made some inquiries relative to the two species of Moths, *Acronycta Psi* and *tridens*, which although so similar in the perfect state as to be scarcely distinguishable, are produced from larvæ very different from each other.

Mr. Lowndes read some notes on the habits of different species of Ants collected by him in Australia. One species he had observed ranged over an area of at least a thousand miles with-

out any variation (a fact of some importance in reference to the geographical modification of species). He had also observed that when its nest was built under stones of a black colour the stone was left uncovered, but if the stone were white or light coloured, it was covered with charcoal or other dark material, the object of which, as suggested by the President, being the increase of temperature arising from the dark colour. The species of the genus *Polytracha* make their nests of leaves, the margins of which are glued together by the insects; but one species forms burrows in the stumps of the *Eucalyptus*, which is so hard and heavy that it sinks in water. The species of *Myrmecia* are of large size and very formidable for their stings, the poison of which is, however, of a very transitory kind. Their larvæ when full grown form a cocoon which is by no means a common character in the *Myrmecides*, to which division of the family the genus belongs. One of the species, *M. nigro-cincta*, is able to leap to a distance of 2 or 3 feet, although the legs are not apparently dilated or formed otherwise than for running.

A letter was read from Mr. C. A. Wilson, of Adelaide, giving an account of a recent exploration across the interior of Australia, with notices of some of the insects observed. In the splendid family of Beetles, *Buprestidae*, not fewer than 150 species had been collected by Mr. F. G. Waterhouse.

Mr. W. C. Hewitson read descriptions of two new beautiful exotic species of Butterflies, from Bogota, one named *Morpho Alexandra*, in honour of the Princess of Wales; and the other *Papilio Burchalii*.

Mr. Rowland Trimen sent descriptions of three new species of Butterflies captured in the neighbourhood of the Cape of Good Hope, specimens of which had been forwarded to the Society in a post letter.

Herr Vollenhoven, of Leyden, also forwarded a notice of the great work on which the Dutch Government is at present engaged, containing an account of the zoological productions of the Dutch settlements in the Eastern Archipelago, the first entomological part of which is nearly ready for publication.

THE TOAD,

DOES IT HABITUALLY CONSUME WORMS?

TOWARDS the close of one of those wet misty days usual in the autumn, my attention was drawn last year to one of my noble friends, a toad, seemingly in a stooping position, or with his head down. As I had never seen him in such a position before, I watched his movements. On perceiving me he resumed his erect position, and I then saw protruding from one side of his mouth part of a worm, in size evidently above the medium; the so-called head of the worm being within his mouth, whilst the opposite extremity struggled hard to release itself from the firmly-closed mouth of its captor.

I stood quiet, determined, if possible, to watch the issue; but my patience exhausted, I moved to go, when the toad moved forward also, and at the same moment swallowed the worm. It seems to be probable, that the toad habitually does consume worms. This idea is strengthened when we take into consideration the amount and frequency of its excrement generally, which certainly is decidedly opposed to the idea that the more minute insects which it is known to catch during the day, are its only sustenance.—W. EARLEY, *Digswell*.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE recent heavy rain will render the operation of continual surface-stirring necessary; a light thin-tined fork to be used, as it enters deeper into the soil and makes more effectual work than any other implement. Small crane-necked hoes are useful for stirring the soil amongst seedling crops. By all means avoid treading on the soil after the operation is performed, especially if the soil is at all wet. Continue to trench up all ground remaining or becoming vacant. *Asparagus*, the beds are now coming into full bearing. The practice of allowing the shoots to grow longer out of the ground before cutting is becoming more generally adopted even by the market-gardeners, and ought to be universal: an inch or an inch and a half below the surface is quite enough. Do not permit any to run up at present, not even weak ones, and give the beds occasionally a good supply of manure water with a little salt dissolved in it. *Basil*, as also *Capsicums* and *Chilies*, should now be undergoing the process

of hardening previous to planting out. A portion of them to be retained in heat for an early supply. *Beans*, make another sowing of Longpod, or Green Windsor, or any other approved sort. Earth-up the early crops, but if the weather is dry give them a good watering previous to doing so. *Broccoli*, the seed-beds to be frequently sprinkled with soot, wood-ashes, or dust of some kind, to protect the young plants from the attacks of that is commonly called the fly. The young seedlings sometimes disappear without any apparent cause; but if they were looked over about ten o'clock at night with a lighted candle, the cause would appear in the shape of slugs. Two or three doses of quicklime sprinkled over them will prove effectual for their destruction. *Carrots*, if the main crop has failed, sow seed of the Early Horn immediately. *Cabbages*, continue to plant them out from the nursery-beds, and also the Cauliflowers as they become large enough, and keep the earth well stirred about those advancing. Cauliflowers and Cape Broccoli may still be sown for a late supply, but there must be no delay. *Parsley*, thin the early sowing as soon as it is up. *Peas*, earth-up and stick the advancing crops, but before doing so they should be watered if the soil is dry. Make another sowing. *Potatoes*, hoe and stir the soil between the rows of the early out-door crops. *Radishes*, sow every ten days, and Lettuces every three weeks, and Mustard and Cress every four or five days; all in quantities proportioned to the demand. A few of the earliest Radishes to be left to seed, the pods for pickling. *Scarlet Runners*, make a sowing in the open ground to succeed those that may have been forwarded in boxes, and which will be ready to plant out the latter end of the week. *Turnips*, thin the advancing crops, and make another sowing of Stone to come on in July and August. *Vegetable Marrows*, towards the end of the week have a ridge prepared for turning them out on, and also Cucumbers under hand-glasses. There is no better way than the usual one of throwing out a trench 3½ or 4 feet wide filling it up with fermenting matter and returning the soil, but if the soil is not of a light nature, it is advisable to get some light prepared compost laid where the glasses are placed. Where any main crops have failed no time should be lost in putting in more seed.

FLOWER GARDEN.

The late rains will be favourable for recently-planted shrubs, and now the soil is damp no time should be lost in completing whatever in the shape of planting remains on hand. The herbaceous ground to be well cleaned and neatly raked over; this cannot well be done sooner, in consequence of many species being late in vegetating.—See that standard Roses are secured against high winds. Those which were budded last season to be again gone over, and all the buds and suckers which proceed from the stock to be removed; the inserted buds which have made shoots to be stopped back to three joints, which will cause them to take a firmer hold of the stock, and will increase the size of the head. From those which are intended for budding upon this season, rub-off all the buds with the exception of three well-placed ones at the top of the stock. As the state of the soil and weather is now favourable for commencing with the bedding-out stock, a start to be made with the *Calceolarias*, *Verbenas*, and similar plants, reserving *Heliotropes*, *Ageratums*, and the more tender kinds of *Geraniums* for the latest planting when the danger from frost of any severity may be supposed to be over. Branches of evergreens are easily obtained about most places, and a sprinkling of these stuck into the beds after planting will be of great service in protecting the plants from the drying effect of bright sunshine, and will also help to ward off frost.

FRUIT GARDEN.

Moderate disbudding, or, rather, thinning, the shoots to be persevered in, but they must now be removed with a sharp knife, and not broken off, as the shoots are acquiring consistency. Some of the strongest shoots of Peaches intended to remain will require to be tacked-in. Stop the strongest shoots of Vines a joint beyond the fruit, and commence nailing-in. Apricots being generally used for tarts to be left until they are large enough for that purpose. Pay attention to the destruction of insects on fruit trees, in order to afford the young shoots a fair chance to make healthy growth. See that recently-transplanted trees are not allowed to suffer through want of water. Look after the caterpillar on the Gooseberry trees.

GREENHOUSE AND CONSERVATORY.

Where a large quantity of hardy shrubs is annually forced, either to decorate the drawing-room or conservatory, it is not desirable to pot a fresh stock each season, for a number of the

deciduous shrubs—as Roses, Lilacs, Honeysuckles, &c.—may by proper treatment be made to bloom for several successive seasons: select, therefore, the most suitable plants when removed from the houses, and give them some kind of temporary shelter to gradually harden their foliage. Those cramped for pot-room to be shifted into pots a size larger in rich turfy loam; towards the end of the month plunge them in an open situation that the wood may ripen early; those plants, from having been previously forced, will bloom earlier than the new stock, of which a portion each year should be potted to replace such as become useless for further work. As soon as cold frames and pits are clear of bedding stuff they should be occupied with young stock of hardwooded plants, for the summer growth of which they are better adapted than large houses. Fuchsias for late blooming must not be kept too warm, they should be placed in a moist shady house where they will grow much more freely than in a high temperature. Conservatory-beds will require water, as also all large plants in tubs—Camellias, particularly, being in active growth will require a liberal supply; a watering of manure water will be advantageous. Cut down and place in a cold frame the choicest Cinerarias for suckers, and put in a stock of Chrysanthemum cuttings for autumn display. The different Ipomæas and Thunbergias being subject to red spider should be well syringed, to prevent the pest gaining ground. Have an eye to the propagation in due time of stock for succession or winter flowering. Take care to secure cuttings of such plants as Clerodendrons, Poinsettias, Eranthemums, Erythrinas, and of those useful winter-blooming plants Euphorbia jacquiniæflora and Gesnera bulbosa.

W. KRANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

STILL cold winds, a low barometer, and only threatening rains, which now, in moderation, are much wanted. Run the Dutch hoe among all advancing crops, to cut-up young weeds and prevent cracking—such as among Cauliflowers, Cabbages, Potatoes, Onions, &c. A little hail and snow and a low barometer are signs that we shall get some rain ere long. Expecting it to come, have had all our watercourses cleared that we may preserve what we can for watering purposes, as water is scarce with us. Gave Cauliflowers a little manure water, to cause the heads to come strong and dwarf. We had set our hearts on having a tank made with divisions for different kinds of manure water, near to a large tank that takes the water from the roofs of certain glass houses and sheds, but we did not succeed in our aim, and did no better as to securing some large old casks; those we have used for the purpose being old oil-casks, and in use for the best part of twenty years, but now so worn-out as to be unable to hold water.

Well, as we could not have what we wanted, we made shift with what we could obtain; for to be destitute of clear lime and soot water, and manure water well fermented, appeared to us to be almost as great an inconvenience as for a fish to attempt to get comfortably along with a scarcity of pure water. Two modes presented themselves involving only a little labour, and little but the expense of the labour. The first was to make a large trench or pond with sloping sides, and cover the bottom and sides with stiff puddled clay and tar, and some rough gravel beat into the sides of the clay. This would have taken more time than we could spare, and it would have required us to have waited until the tar dried, or the water might have had too much of it. The second mode was to sink the old ricketty barrels, that had seen such long service, in the ground, and make them waterproof there; and that was the plan resorted to.

A deep trench was dug, deep enough for the top of the barrels to be level with the surface, and wide enough to leave at least 9 inches all round them. The surface soil was removed, but the clay below was saved for repacking round the barrels. Each barrel in turn was handled as carefully as possible to prevent it falling to pieces. The bottom was then thickly painted with tar outside. The place where it was to stand was prepared with soft clay mixed with tar, so that when set up there was no chance of water getting out by the bottom. We would have tarred the inside, only we could not afford to wait for the tar drying. The outside of the barrel was, however, examined, and all rents, fissures, and deficiencies filled up with stiff clay putty, and then tarred heavily all over; and, as the clay was being rammed firmly against the barrel, at every layer of 4 inches or

so a little tar was trickled round the barrel, so that when the wood of the barrel is more thoroughly rotten and decayed the openings between the sides will still hold water. The surface of the ground round the top of the barrels was of clay well beaten, covered with a thin layer of tar, and then with a layer of sand, which will become hard and firm. The whole looks so nice, and the barrels are so much more easily filled and emptied, that we are surprised we did not think them years ago. The only disadvantage is that we must place hurdles round them to prevent four-footed or two-legged animals falling into them, if they should go in a dark night where they have no business.

Whilst on this subject we may hint that those who use liquid manure made from sheep, deer, cow, or horse droppings would act safely in pouring boiling water over them, and covering them up with a lid some hours before filling up with common water. The boiling water will scarcely leave anything alive in the droppings.

General routine with Cucumbers, Dwarf Kidney Beans, Peas, &c., much the same as last week. Moved Tom Thumb Peas in orchard-house that had done good service to the foot of a wall, where they will come as often and as quick as wanted. Although Peas are Peas we never think that those gathered under glass, however open, and cool, and airy, are quite so good as those obtained in the open air. Put small stakes to those planted out in front of orchard-house now in full bloom. Watered Dwarf Kidney Beans behind them to cause them to come regularly. Those in boxes will need planting-out soon.

FRUIT GARDEN.

Planted-out Strawberry plants that had been forced and the crop gathered; removed breastwood partially from Peaches, Apricots, and also Pear trees; kept houses at much the same temperature as previously stated; thinned shoots and stopped shoots on fruit trees in houses; drew a hand quite dry on sunny days over bunches of Muscat Vines in bloom; watered Figs, and planted-out more Melons as room could be had for them.

PLANT DEPARTMENT.

Shifted Geraniums, a few Ferns, Fuchsias, &c.; moved more Cinerarias and Primulas from conservatory, and replaced with Fuchsias and Pelargoniums; potted Fancy Geraniums for beds; made cuttings of, and divided Dahlia roots; planted a number in a slight hotbed, giving them about 3 inches square, and leaving only one stem to each; potted Gloxinias, Begonias, especially fine-foliaged ones, also Browallias, Balsams, and pricked-off numbers of Lobelias, and other small things. Turned out in Celery-trenches great quantities of fresh-struck Verbenas, Geraniums, &c., putting them in sandy leaf mould and hardly breaking the balls, for reasons previously given; watered Calceolarias and Geraniums formerly turned out, as the weather has been so dry and parching.

FLOWER GARDEN.

Rolled, mowed, cut up Daisies with a long-handled double-bladed daisy-knife, worth a dozen of daisy-rakes. Dug down beds in flower garden; and as in some parterres that we wish to be level, the ground had got considerably above the grass, took a lot away, to secure the level character, and used it to dress borders which are rather low, or to raise beds which we wish to be in the pyramidal form. Calceolarias are now mostly exposed night and day in their earth temporary beds.—R. F.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

SEEDLING PETUNIA AND VERBENA (Inquirer).—Send them to the Floral Committee of the Royal Horticultural Society, Kensington Gore, directed to the Secretary, T. Moore, Esq. The next meeting of that Committee is on the 5th of May.

SEEDLING GERANIUM (Hortus).—Too much depends upon the habit of the plant for us to give an opinion upon it as a bedder. In colour it is like Christine. Cannot you induce your near neighbour, the Rev. H. Dombrain, of Deal, to look at it?

VERBENAS, PLANTING OUT FROM CUTTING-PAN (W. P.).—You may plant them out of the cutting-pot with perfect safety at the proper time and in moist weather; but they will be later than those which have been potted-off and established some time in small pots. When, however, space is scarce it is often necessary to plant direct out of cutting-pots.

AZALEA INDICA—CUTTING DOWN OLD PLANTS (W. P., Camborne).—If your plants are old and unsightly naked, it would be better to plant them out of doors in some favoured spot and procure some young ones, as they rarely do well by cutting down; whereas by planting-out they may possibly make good useful shrubs in a few years.

CINERARIA, CUTTING DOWN AND SOWING SEED (W. P., Camborne).—If Cinerarias be allowed to ripen their seed, many of the plants will die afterwards. Thus it is better to cut down the plant before the flower be entirely faded, and by the appearance of the collar of the plant you will see if there be any suckers rising; if not, the plant will likely die. It is, therefore, better to sow a quantity each year, and the earlier in May the better. Sow in a pan of sandy soil made somewhat firm, and place it in a shady situation; prick the plants out when they are large enough to handle, and pot when required.

SEEDLINGS (M. Errington).—Your seedling Cinerarias and Tropæolum, though good flowers, are not sufficiently novel and distinct from other varieties in cultivation.

MELON-LEAVES SPOTTING (An Early Melon-grower).—Are you sure the leaves are affected by disease, and not by scalding, by having a powerful sun shining on moist foliage, and air not given early enough?

ARRANGEMENT OF STAGES IN GREENHOUSE (A., Glasgow).—We would certainly narrow the front stage to 2 feet, and make the back one $4\frac{1}{2}$ feet. You could have that flat, or raised in a series of four or five steps to the back wall. If the floor is paved, large pots would be best for the climbers, otherwise you might have a border at back for the purpose.

HEATING A PIT FOR BEDDING PLANTS (W. Cobb).—The best would be hot water and pipes. The cheapest to be effectual would be a brick Arnott's stove lighted from the outside, placed in the middle of the pit near the back. It is a pity you cannot make the pit a foot or two wider.

CAMELLIAS NOT FLOWERING (H. Y. G.).—Your Camellias, we presume, are all right. Continue the same process, and give more light and air in July and August. You do not expect them to bloom now, surely. November and January would be early enough.

FLOWER-GARDEN PLANS (A Novice, Yorkshire).—Both borders will look well.

MOLES IN VINE-BORDER—CISSUS DISCOLOR LOSING ITS LEAVES (Constant Reader).—We should not like moles in our Vine-border—they would be apt to cut the roots that came in their way. If the top of the Cissus is alive, it will break in heat and moisture. Syringe it well, and do not water heavily until it break. If the top is dead and the bottom alive prune it back, and give but little water until it break. Then shake away part of the old earth, repot, and give bottom heat if possible.

FUNGUS ON PEAR-LEAVES (D., Newcastle).—There is a fungus on the leaves, the result of imperfect root-action, and we think, rather much moisture or deficient drainage. Stir the surface soil to let the air into the soil, and water only as wanted.

AMARANTHUS MELANCHOLICUS—ZELINDA DAHLIA (Q. Q.).—The *Amaranthus melancholicus* is not so hardy as Orach, nor does it break so well. It will bear nipping if the season is warm, and will mix well with Bijou if it grow freely enough; but we did not get on well with it. Ours needed no pegging-down. We think it needs a warm place and a hot season, but we would wish to know the general result last year of those who tried it. We would not stop Dahlia Zelinda. You cannot get the flowers too early. If at all much taller than you want, plant sloping, or peg the plants down. The leaves were much injured; but the one with the most yellow we should say was Golden Chain and the other Golden Fleece, but cannot be sure.

CINERARIA MARITIMA TREATMENT—BEDDING PLANTS (S., Hampton Court).—For the *Cineraria maritima* seedlings, nip the points out by all means. You can do nothing to increase the silvery appearance, except, perhaps, by growing them in poor soil. They will be more silvery as they get older towards autumn. Then we would advise you to keep the best plants over the winter, and propagate from them by cuttings instead of by sowing seeds. Seedlings will not compare with plants so raised, though they will look very well if you have none of those raised from cuttings of the old plants near them. The Sultan Calceolaria is a better pot than bedding plant. In a bed, for a month or six weeks it will be everything that you could wish; but in most cases, unless great care and attention are given, it will be patchy afterwards. Your edging with Flower of the Day Geranium, and bounding with *Lobelia speciosa*, will do well. Were we to depend on Sultan we would plant thickly, say 7 or 8 inches apart, and when the plants were growing freely we would cut over every other one so as to obtain a succession of bloom. It is doubtful what the beginning of May may bring with it. Instead of planting out at once we would plunge the pots, or rather turn them out, without breaking the balls, into a sunk bed anywhere where you could give them a little shelter if necessary. If you can do that in the beds you may plant at once; but having things thick together enables protection and watering to be easily given. See "Doings of Last Week."

SEEDLING POLYANTHUS (W. W.).—Not knowing the habit of the plant, or whether it is an abundant bloomer, we cannot give a decided opinion on its worth as a bedder. Polyanthuses generally are not good for the purpose, and such a combination of yellow and crimson renders it still less decided in tint for bedding.

BOTTLING GOOSEBERRIES (A. W. A.).—Gather the fruit dry and when little more than half grown; pick clean, put into wide-mouthed bottles, and shake gently down till the bottles are full. Cork these tightly, put them in a moderate oven, and let them remain till heated through. Beat in the corks tightly, cut off the tops, resin them over, and keep in a dry cool place. Wood-ashes form an excellent manure. For the best mode of using them consult "Manures for the Many," which will shortly be published at our office.

HARDY ANNUALS (T. G.).—You may sow in pans, and keep close, warm and dark until the seedlings appear, and then give light and air by degrees. We would sow some in this way, and sow the rest in the open air, as the ground is now getting warm. In sowing *Portulacas* and *Mesembryanthemums*, it is best to water the pot, let it dry a little on the surface. Sow the seeds, then sprinkle with sand or fine soil, press down, put a square of glass and a piece of paper over the pot, or the paper alone, and allow the paper to remain until the seedlings appear. So managed, they will generally come up without watering. If you have occasion to water before or afterwards, soil the pot instead of watering overhead. The easiest way to do this is to hold the pot in a pail of water, allowing the water to rise from below to the surface. Zinnias require an ordinary amount of water. To do well they must have no stoppages in their growth. For more particulars we refer you, "C. W. H.," "G. T.," "N. O.," "X. Z.," and others to an article to-day on Annuals.

SCIENCE OF WINDOW-GARDENING (A Subscriber, Swansea).—Mr. Bosanquet's work is published at our office, price 6d., or free by post 7d.

SEA-KALE.—Would our correspondent "T. W. B.," whose communication appeared in No. 106, oblige "W. M." by stating in what month he covered his Sea-kale with seaweed, and the date of his first gathering?

KALMIA LATIFOLIA BUDS NOT OPENING (Constant Reader, Dublin).—This may be owing to the check caused by your plants being taken up and planted in a balcony; or perhaps their roots were very much reduced to get them into pots. This, we know, will occasion the flower-buds to refuse to open, and manure water will not repair the injury done. The buds of *Rhododendrons* open more easily, as it would appear that the effort required on the part of the plant to expand them is much less than that necessary in the case of the *Kalmia*, and unless the plant be in health it is unable to do so. When growing in the open ground, it sometimes does not open its flowers as you describe.

VERBENA CUTTINGS FAILING (Constant Reader, Dublin).—We cannot well account for your cuttings damping-off, after being in about three weeks, in March and April. They are often ready to pot-off in that time, and the sooner that is done the better after they are sufficiently rooted. If they are very much drawn, and then suddenly exposed to cold chilly blasts, they will succumb; but, generally speaking, nothing does better than Verbenas in spring. Write us more particulars, and we will give you more advice.

WELLINGTONIA TURNING BROWN (Ada).—If your Wellingtonia exhibits greater brownness than it has done during former winters, and if there are evident signs of weakness in its growth, treat it as you say with fresh loam and leaf mould.

NAMES OF PLANTS (A. Fyde Fulmer, Slough).—*Helleborus viridis*. (W. O.).—1, *Helleborus foetidus*; 2, some *Canna*; 3, *Boronia polygalifolia*; 4, *Dolichos speciosus*. (F. G. S.).—You must send better specimens. 1, *Ajuga reptans*; 2, *Luzula pilosa*. The rest nothing but leaves. (F. J.).—*Eutaxia myrtifolia*, and apparently *Dacrydium excelsum*. (Flora).—Apparently one of the *Holboellias*, but the specimen was insufficient to determine which. Perhaps *H. acuminata*. (A Reader, Dumbartonshire). 1, *Chelanthus pteroides* apparently, but there is no fructification; 2, some *Marchantia*. (A. B. C.).—1, *Myrsine pimenta*, or something very near it; 2, *Rhynchospermum jasminoides*; 3, *Polygala myrtifolia*; 4, *Aphellexis*, without foliage; 5, *Hovea Celsi*; 6, *Eriostemon scaber*. (J. G. Tierbutt).—The leaves are those of *Myoporum acuminatum*. The *Fuchsia* is not equal to many others in cultivation.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

COMING POULTRY SHOWS.

THOSE who have bred good and early chickens this year, and we believe they are many, are beginning to view them with reference to their capabilities as exhibition birds. A may be convinced he has better birds than B; but it is satisfactory to have his judgment strengthened or endorsed by the awards of acknowledged judges, and he likes to see them fairly pitted against all comers.

All do not care to enter for the blue ribands at Birmingham and the Crystal Palace. They rather seek shows of less pretension and shorter duration. We would say to such there is an agricultural Show at Basingstoke at the latter end of May. It is held in connection with the Show of the Hampshire Agricultural Society. Full particulars can be had of Mr. Downes, Secretary, Basingstoke. It is near London, and the birds are only two days absent from home.

Then we have the Agricultural Hall Show at Islington, and the Bath and West of England in June. The latter is always a pleasant Show. It is held in summer in a lovely part of the country, and is a general holiday. Temporary avenues of trees are planted in the streets; flowers and evergreens stretch from window to window; all the bands of music in the country are

put in requisition; guns and even cannon are discharged, and the Show is a fête.

There is one thing we do not understand:—there is to be open judging on Saturday 6th. What is open judging? Are the awards to be made in presence of the public? if so, we do not envy the Judges, nor do we think they can do justice to exhibitors. Nothing requires privacy so much as judging, and where competition is close it is absolutely necessary.

MALAY FOWLS.

I HAD no expectation when I sent you my first letter on the "Characteristics of Malay Fowls" that it would have induced so much correspondence.

In the first place, I thank you for inserting my letter and for your observations thereon; in the next for observations made by correspondents on this interesting subject. We have now, I think, pretty clearly elicited what points we should aim at in breeding Malays; and it may be expected that in a few years perfection will be arrived at in this breed of poultry.

Your correspondent "Y. B. A. Z." is pleased to designate my fowls as "too handsome." They were considered by many persons living here as much finer and more beautiful than those to which the first prize was awarded; but, like myself, these friends of mine knew but little of what constituted a good Malay; we were all mistaken. This circumstance may probably illustrate some of the disputes which occasionally arise between exhibitors and judges; the former thinking their fowls ought to have had a prize, when, in fact, they were, like me, not aware what were the essentials to constitute a good fowl.

I am free to confess that if I had been appointed to judge birds like those exhibited at Devizes, without, of course, knowing who were the exhibitors, I should have given the prize to my own pens; and I am now, after this correspondence, quite convinced I should have done wrong.

I have never disputed the decision of any judge; I consider it would be a reflection, not only on the Judge in question, but also on the Committee who appointed him. All committees, I believe, do their best to secure persons to act in this capacity who are esteemed competent and whose integrity is unquestionable: under these circumstances, therefore, exhibitors would do well to forego their feelings if they should consider that justice had not been done to them, remembering that we are all fallible creatures, and the best of us may possibly err sometimes.—JOHN JAMES FOX, Devizes.

RULES FOR POULTRY-JUDGING.

Are the new rules for judging to be adopted at the Show at Islington? If they are, where can I procure them? Will you exert your influence in this matter? I and others are now breeding and selecting for exhibition in the autumn and winter. The Poultry Club is tolerably certain of carrying its point and having a voice at most shows. As there will be no getting away from the *litera scripta*, we ought now to know what we are to try for; otherwise the efforts of the Club will end in placing us in the position whence they say they wish to extricate themselves—viz, that of exhibitors who know not what to exhibit. I think if the rules are not ready for publication now, their application to shows should be deferred till next year. What causes the delay?—ONE IN THE DARK.

A PRAYER FOR BIRDS OF PREY.

THE destruction of birds of prey has been of late years so indiscriminate and so universal, owing to the very strict preservation of game, that many are extinct where they formerly abounded; and I venture to invite the attention of your readers to a list of birds formerly not rare, but which now do not exist in this district, some of which might, if a merciful consideration were extended to them, still enliven our country lanes and woods, the toll levied by them being a very unimportant tax on the produce of the races which supply them with food.

The district in which the birds enumerated have been seen is in the west of Essex, extending from Waltham Abbey to Dunmow, including the valley of the Stort. The list has been prepared and given to me by Mr. Daniel French, of Sawbridgeworth, who has through a long life never failed to give the most acute attention to birds and their habits. I send it to you

precisely as it has been given to me. Cannot the proprietors of woods and coverts be induced to order their keepers to abstain from such unremitting war as they wage on these classes?—T. F. K., Sawbridgeworth.

"BIRDS OF PREY—(FALCONIDE).

"ROYAL EAGLE.—Was shot twenty years ago on Tukely Forest, Essex, and I remember one being shot at Waltham Abbey in the marshes.

"OSPREY OR FISHING EAGLE.—A very fine one once lived two or three years about Latton and Nettleswell. I have sometimes been very near to it. I do not know what became of it at last. One has since been shot at Pishobury, Sawbridgeworth.

"KITE.—Formerly at Great Parndon, used to breed in Parndon woods; they are all destroyed.

"MOOR BUZZARD.—There used to be a tract of boggy ground extending from just below Latton Mill down to Burnt Mill with several woods. I have there seen this rare bird two or three times, but have not known it to continue there.

"COMMON BUZZARD.—This was so frequent that I have seen it alight on the barn where I lived, and it used almost continually to be sailing over the meadows; they bred in Latton and Nettleswell woods, not one now remains.

"GOSHAWK.—Used to breed in Hyde Hall wood, Sawbridgeworth.

"SPARROW HAWK.—This active and interesting bird is now very seldom seen, it used to be frequently so; if the farmers execrate the Sparrows they should preserve this Hawk, as its food consists almost exclusively of Sparrows.

"LANNER.—I once saw this large Hawk in Hyde Hall wood, Sawbridgeworth, and I have seen it both in Harlow and Latton Park woods; but it has always been very rare.

"PEREGRINE FALCON.—This has been shot in Stansted Marsh, Hertfordshire, in Gilston Park ditto, and I have seen it in Epping Forest.

"KESTREL (the Hovering Hawk).—This beautiful and interesting little bird that used to enliven the country by his pretty hovering and his plaintive note, is now almost exterminated by the keepers; it meddles with no sort of game, and no bird is of more use to farmers. Its food consists if not exclusively of mice, very nearly so. It enters barns and other out-buildings when not too public in the same manner as Owls. Wherever a nest used to be found which was generally in the old nest of a Crow or Magpie, it was invariably found to be lined with the skins of mice; but in spite of all its services and its beauty it is gone! destroyed by rascals.

"HOBBY.—This small Hawk was more rare than either of the two last-named, and appeared to prey mostly on the larger insects, as it was generally hawking round trees or darting very rapidly along; it kept secluded in woods.

"MERLIN.—This is the smallest of the native Hawks. I once knew a nest with two young ones to be taken in Ongar Park wood, Essex; I had the care of one of the young ones for some months. One a few years since chased a Sparrow into a greenhouse at Sherring, Essex, and, of course, was killed by the man who caught it.

"This is all the species of the Falcon tribe I have been accustomed to know.—D. FRENCH."

NATURAL HISTORY.—We saw the first Dottrell on Wednesday last. We have seen but one.

SWARM OF BEES IN APRIL.

On the 26th ult. we had a swarm of bees here (Linton), from an old hive which, in company with two others, had never been fed all winter.

As it is unusual for bees to swarm in April, I record this instance as the first that has occurred with me; but I believe, three or four years ago, one of my neighbours had a swarm on the 28th of the month. This season, owing to the bright sunny weather, I have no doubt but there may have been several swarms during the month, especially where the bees have been fed, and the situation a favourable one for their doing well.

Last year was by no means a good honey season, but I attribute my bees doing pretty well to the fact of there being so few bees in the neighbourhood. The wet season of 1860, and subsequent hard winter, were fatal to many stocks which have not yet been replaced: hence there was a wider field for those remaining, and they consequently did better.—J. ROBERTSON.

B. & W.'s APIARY.

(Continued from page 270.)

To keep your apian readers "posted-up" in my proceedings I will now recount the events of the last three weeks in order. The operations recorded at page 269 took place March 21—a venturesome time to compel bees to begin artificial-queen-rearing. The plan sketched out there was pretty closely adhered to—that is to say, on the 30th I "made a swarm of D by driving it into a box well stored with comb and food." 2ndly, "D, when cleared of its adult population, was placed in the room of A, after shifting into D the Italian queen and population of A." 3rdly, "A with its Italian brood was put in place of F, setting F over it after catching and destroying its drone-breeding queen." Thus far on the 30th and 31st. I found a large number of drones in F, hatched and unhatched, which have survived, and are now (April 13th), flying in and out in full vigour. Some of them are well marked, but the greater number differ in no respect from common English drones.

On Saturday, the 4th of April, I took off top F, and expelled the bees, compelling them to return home to the lower box, and a good deal of drone-brood was sacrificed. The bees were very savage, as, indeed, they have been throughout all my operations this spring; nor was there any difference between the temper of the Italian and English bees. The most surprising thing, however, was that the bees of F had made several royal cells amongst the drone-brood, and at least one of them was occupied by a grub floating in royal jelly! Had the bee dragged up an egg or young Italian worker-grub from the hive below, or was this a case of mistaken instinct? Anyhow I thought it fortunate that I had taken off this box in time, as there must still have been Italian brood in the hive below of an age suitable for rearing a queen. But this set me thinking that, perhaps, B was in the same predicament: accordingly the same day, exactly a fortnight after the queen of this stock had been destroyed and brood given to them, I examined B, and found the Italian brood-comb with most of its bees hatched, but no royal cell in it. There was one, however, sealed up among the drone cells! Great curiosity did I feel to examine it, but prudence prevailed, and I restored it to the hive, making all snug again as before, in the hope that they might have carried a worker-grub thither, and that in due time a queen would issue from the cell. On the 10th of April, however, I discovered the bees in B in a state of violent agitation, as they always are when their loss of a queen has been perceived. If they had not been so savage I should have taken out their royal cell again to inspect it; but the life of every bee is precious at this season of the year, and the hive was thinly peopled. Assuming, therefore, that no queen was hatched and that the bees had lost hope, I proceeded to the fourth and fifth operation (see page 270), and drove E, queen and all, into an empty box full of comb, and placed E with its brood over B. In a very short time the lower hive was deserted, and peace reigned among the agitated bees.

The long and short of all these changes is that I am still uncertain whether I have succeeded in gaining even one additional Italian queen. The queen of B, should the bees rear one after all, will be almost pure English, but she may be impregnated by a pure Italian drone. Such are some of the difficulties which attend the establishment of the Italian race of bees in this country.

All the hives, however, appear to be doing well. They now stand as follows:—

A. Pure Italian queen (now strong).	B. Bees in process of rearing a queen out of English brood (strengthened).	C. Vacant.
D. Hybrid Italian queen (strong).	E. English queen (strong).	F. Bees rearing a queen out of Italian brood (strengthened).
G. Vacant.	H. English queen (straw hive; strong).	I. English queen (straw hive; weakish).

—B. & W.

FEEDING BEES.

DOES "AN AYRESHIRE BEE-KEEPER" not find his mode of spring-feeding described at page 286 impede the ventilation by partly stopping up the entrance, and bees descending from off the brood to feed during cold frosty nights get as well as if chilled, and consequently perish? These evils do not apply in

the bottle or other top plan; besides it seems more natural, the food being supplied as near as possible to where it is to be stored.

As this seems to be an open question, it would be interesting were some of your many experienced contributors to express their opinions. Would "AN AYRESHIRE BEE-KEEPER" say if it is by this mode, or how he administers his autumn or main supply?—AN INQUIRER.

A DESERTED HIVE.

I AM obliged to "AN AYRESHIRE BEE-KEEPER" by the notice he has taken of the communication to your Journal by one so completely a novice in bee-keeping as I am. Allow me to ask how the narrow tins he recommends can be used below? How are they to be introduced into the hives? They cannot be admitted through the ordinary opening in the floor-board, and I presume the hive has not to be lifted each time, as thereby the bees would be much disturbed; moreover, the comb comes too near the floor-board to allow even a razor-strop to be introduced unless a groove to receive the feeding-trough were made in it. Were this plan adopted, when it was not in use the trough might be reversed, and so the floor-board might be refitted to its ordinary level.

But alas! these schemes are to me visionary, for my hive that on March 4th appeared to be doing well was deserted by its occupants about a fortnight afterwards. My neighbour told me that he noticed the bees weak and scarcely able to return to their hive at midday. On examining the hive I found it empty of living bees and with very few dead. I looked most carefully for the queen, but could not find her. There were bee-bread, a few young bees in the comb, some just issuing from their cells, but no honey nor stored sugar. I could not at all account for the desertion, unless the opening at the top where the feeding-trough was placed had made the hive too cold and draughty for hatching the young, and so they went to look for a more genial home. My hives were in a compact wooden bee-house, so that they are not much exposed to any alteration of weather, and are quite protected from sun, wind, or rain. When I begin again I must hope for better fortune.—B. J. S.

[Yours may be a case of desertion similar to one we have just witnessed in our own neighbourhood. Although ample food was presented to them in a trough on the top of their hive, the bees refused to ascend into it, and deserted their habitation and young brood in all stages to seek their fortune elsewhere. We believe the same food would have been accepted without scruple if offered by means of an inverted bottle, and that in all probability the result would have been very different.]

REPLY TO MR. FAIRBROTHER'S INQUIRIES.

WITH regard to the query of Mr. Edward Fairbrother, page 236, "What is the best method of insuring a succession of fertile queens?" it is certainly not easy to answer, for one that may be prolific now may be the reverse next year, from circumstances not easily explained. The best method I know, is to have a thorough knowledge of all the stocks in autumn, and to keep those only that have already proved themselves prolific, and young queens and combs, although I have had a queen seven years old, breeding well in all these seasons, which did as well the last year as the first. Another remarkable circumstance was, that I never saw it breed more drones in a season than about fifty, but I do not think that any advantage.

"Are there any facts determining the flight of bees in search of honey?" I have never been able to come to a definite decision on that point, for I never was in a district where bees were further from each other than six miles. I have seen them working often midway between the two places. In 1858 I had a hive that made 20 lbs. of heather-honey, from at least three miles distance, in ten days. Of course, this was scarcely the half of the weight that those made which were placed in the immediate vicinity of the heather. I have proved that bees when within one mile of an abundance of the flowers that they work on, will make in a good day exactly the same weight of honey as there is weight of bees in the hive.

[We think there must be some mistake with regard to a queen bee living and continuing fertile during seven years. Also, with respect to bees returning from six miles distance. We once had two apiaries about two and a quarter miles apart, and although

we frequently shifted stocks from one to the other during the height of the working season we never saw one come back. Will Mr. Fox who has, or had, four different apiaries within moderate distances of each other, favour us with his experience on this point?]

I once knew of some hives that were removed six miles to the heather, and in the evening when the proprietor visited the spot where his bees had stood, was astonished to see large clusters of bees hanging on the posts. Of course, this might arise from the bees flying to the same direction they used to stand in, and their coming to the place where they used to work would naturally lead them to their old stand. If spared in health I hope by the end of the summer to be able to come to a decision as to how far they fly, from watching the Ligurians, as I think there will be none in this locality but my own.

With regard to the honey season, the bees in this locality commence carrying pollen on an average about the 9th of February, but no honey till about the second week of April. They then begin to get a little honey from the blossoms of the gooseberry, &c., always increasing in quantity as the blossoms come out, but never in larger quantities than what is barely sufficient to carry them through with their labours till about the first week of June, or, according to the seasons, varying from the first to the third week; and they continue from two to three weeks working on the white clover flower, or blossom of the bean and charlock, or wild kail (I do not know the botanical name of the last-mentioned), close to their proximity. So that if that time is wet they produce nothing beyond, perhaps, a few well-peopled hives, but void of honey or combs, as has been the case in 1860-1 and 1862, but in good order for the heather harvest, as we often find the bees producing greater numbers in showery weather than in bright sunny weather when much honey is to be had. The only honey harvest I have had these three years was in 1862, at the heather; it lasted from the 13th July till the end of August, when my hives made from 40 to 50 lbs. of honey, besides keeping themselves during that time.

As to their increase and decrease of weight at different periods, I have all along weighed my hives at different times of the day—thus: if we weigh a hive in the morning that is likely to make weight during that day—suppose it makes 5 lbs.—weigh it the following morning and you will find it about one-sixth lighter than what it was the preceding night; and, again from their great decrease at certain periods—viz., perhaps after one week's fine honey weather when the hives were fast increasing in weight and well filled with young brood, &c., the weather breaks and, perhaps, continues broken for a long time. At this time, perhaps, a hive weighs 50 or 60 lbs., one-third, perhaps, consisting of young bees and liquid stuff for their sustenance, so that the honey is immediately sealed and their labours now past on account of the weather. They allow all the young bees to come out and not replacing others, and by the extirpation of the drones, &c., all tending to lighten the hive which truly astonishes many; but if carefully watched and understood it is easy to understand the cause of some hives making more and losing more at one time than another.—A LANARKSHIRE BEE-KEEPER.

ASPECT OF BEE-HIVES.

MR. BEVAN FOX has given his opinion in what aspect bees ought to be placed, and no doubt if we had a climate the same as Italy he would be right. I dislike moving bees from their original site, unless to a great distance; but if the hives during winter and spring were merely turned on their stands to the north, it would save a great many bees from being chilled to death in cold weather, particularly when snow is on the ground, and the sun's rays begin to reflect more than usual heat.

In former Numbers of THE JOURNAL OF HORTICULTURE I have advocated a south and south-eastern aspect as the best, and in the changeable climate of Great Britain, with our hot summers "so few and far between," I am still of opinion something near the south is the best.

I once visited an Oxfordshire bee-keeper who changed the aspect of his bees every autumn, and also moved at least half a dozen of his hives several yards. On examining these last immediately after, the bees were fighting desperately, having mistaken other hives for their own, and this continued for at least a week, to the great decrease of their numbers.

Virgil recommends very properly a sheltered situation, and at midday heat a little shade. But in the last three summers (1860, 1861, and 1862), what shade has ever been required even

in the southern part of England? Nevertheless, I have seen terrible effects from a neglect of shade by careless bee-masters, such as the honey running out at the entrance of hives, the bees, in a state of almost madness, flying at every one who came near, and certain destruction by one-half or more of them being suffocated in their own sweets, by the melting of the combs. Early swarms are destroyed first, as the combs melt much sooner than those of old stocks.

Those hives placed under high walls are generally affected by heat first, and the real safeguard against being surprised in one of our hot summers, similar to 1846, or July, 1859, is a wooden bee-house, which shades all the hives at noon; and these bee-houses have their disadvantages also, by harbouring spiders and other troublesome insects, and also being, in fact, too much shaded in our cold, wet summers.

On the whole, the best safeguard is constant attention, and bees require constant looking-after. In the spring and autumn the worst enemies are those of their own species which acquire predatory habits and fly a long distance to plunder their weaker neighbours, and this propensity to plunder is one of the few bad qualities they possess, and most difficult to be overcome.—H. W. NEWMAN, *Hillside, Cheltenham.*

COOKING HAMS.—A ham of 10 lbs. should be boiled slowly in a pot without a cover, and that for the space of nearly two and a half hours. To ascertain if sufficiently boiled, try if the skin will come readily off, and if so, it is fit for use. Before sending it to table, the ham is generally subjected to a little ornamental dressing. We do not refer to the ornamenting and covering of the bone with a net or cut paper, but the browning where the skin has been removed. There are two ways of doing this. In the one, you cover the surface with bread crumbs, and keep it in the oven until it attains the proper colour. In the other, you sprinkle sugar on the ham, and pass a red-hot iron over the surface, and thus impart to it that rich glossy brown which so many admire.—(*Scottish Farmer.*)

OUR LETTER BOX.

SHANGHAI HENS DYING (*D. B. Shirley*).—There is no doubt about the case. The hens going on to the nest, and dying without laying, is always an unmistakable intimation that they are what is termed "egg-bound." The egg-passage is in such cases usually encumbered with fat, the passage is rendered by the pressure too narrow for the egg to pass, and inflammation and death ensue. You will see in our Number for April 21st how a Duck ought to be treated under similar circumstances. Treat your hens the same and reduce their food now, for prevention is better than having to cure.

INCUBATOR (*A. A.*).—We know of no maker of incubators now. An advertisement might bring one forward. Gas or argand burners connected with a hot-water apparatus were employed in them. They were expensive, and soon given up by those who bought them.

PIGEONS IN A GARRET (*Woodpigeon*).—Keep Pigeons in a pigeon-house, and not in the garret of an inhabited house; they cannot fail to be disagreeable. Pigeons of different varieties do breed together.

FEEDING BEES (*A Reader, Dumbartonshire*).—When the holes in the perforated zinc become closed it should be removed, and a clean piece substituted; but we have never found this to be the case whilst regular feeding is in progress and the bees take the food freely. If there be sealed honey in a weak hive feeding is, of course, not absolutely required, but may be of service in the spring by promoting egg-laying. In early spring bees appropriate syrup but slowly, and in very cold weather leave it quite untouched.

PROTECTING BELL-GLASSES—UNITING STOCKS (*Gardenia*).—Bell-glasses require to be kept warm by being enveloped in flannel or some other good nonconductor, but need not be fixed with putty or any other cement. We advise you to write to Messrs. Neighbour & Son, 149, Regent Street, London, respecting your second query. In any case killing bees is a wanton waste of valuable life, since, by means of driving, the inhabitants of condemned stocks can always be advantageously employed to strengthen those intended to stand the winter.

CHOICE OF HIVES (*J. W. P., Derby*).—For ordinary bee-keeping a flat-topped straw hive, with central aperture for feeding or supering, in other words, one of Payne's improved cottage-hives, which are supplied by Messrs. Neighbour at half-a-crown, will answer as well as any. But for experimental and scientific purposes we recommend the Woodbury frame-hive, which may be had in straw at a moderate price.

LONDON MARKETS.—MAY 4.

POULTRY.

Strong chickens are comparatively plentiful, and afford proof of the mild winter we have had. Fowls are, and will be scarce, but we think there is every prospect of a good supply during the season.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 64.5° and 41.4° respectively. The greatest heat, 86°, occurred on the 15th and 17th, in 1833; and the lowest cold, 25°, on the 15th, in 1850. During the period 147 days were fine, and on 105 rain fell.

ORNAMENTAL LEAVES FOR GARNISHING THE DESSERT.

I R S T catch the hare and then cook it," is an old adage. The gardener must conform to the rule by first procuring seeds and plants, and then cultivating them in order to have the necessary supply when wanted. The cook as well as the gardener would be of but little use in their way of business without having the proper materials necessary to carry on their various operations.

What, for instance, can be more tantalising to a gardener than to sit down and read, "So-and-so" is admirably adapted for such a purpose, and "such and such" will give a charming effect to "so-and-so," when at the same time, perhaps, the chief in command has little if any of the things recommended? This, then, being a good time to procure seeds or plants from which ornamental leaves can be obtained, a list of the plants which have been used here with good effect may not be out of place.

First, then, I would recommend all gardeners to secure a good supply of the *Poinsettia pulcherrima*: indeed it is almost an impossibility to have too much of this truly useful plant. Having ourselves last season upwards of two hundred plants we found that we were not encumbered with one too many. The richness which the scarlet bracts of this plant give to almost any kind of fruit can scarcely be conceived, especially if arranged on white china and a few Fern fronds intermixed. Next in importance are the beautiful crimson leaves of the *Barbrossa* and West's *St. Peter's Grape Vines*; we find that these latter produce prettier foliage when grown in pots. *Coleus Verschaffelti* and *Ampelopsis hederacea* (*Virginian Creeper*), also produce pretty foliage; also *Copper Beech*, *Mahonia aquifolia*, *Begonia Lowii*, and other varieties. *Caladium*: of this tribe there are some kinds very pretty and exceedingly useful, especially the small-leaved varieties. Some kinds of Pear leaves are very ornamental in the autumn months. *Centaurea* and *Cineraria maritima* will give a somewhat frosted-silver appearance and make a nice contrast to high-coloured leaves.

No. 111.—VOL. IV., NEW SERIES.

I have no doubt that many additions might be made to this enumeration; but with the above and a tolerably good supply of Fern fronds, Ivy, Moss, and similar green materials, a very fair show can be made.

When very large dishes are used on which a miscellaneous collection of fruit is required, some of the following may be employed with good effect:—Gourds, of which there are many very ornamental kinds admirably adapted for the purpose; one or two Tomatoes, Capsicums, Shad-docks, and Oranges with a leaf or two attached; and the *Pyracantha*, *Cotoneaster*, *Berberis*, and *Cape Gooseberry* are also useful in their way for smaller dishes. Most gardeners have access to fruit and flower shows, and yet few see any other arrangement of the dessert than that for which they have to provide.

I have noticed many times, and not without a considerable amount of grief, bunch after bunch of Grapes piled up one above the other in order to gain height; but why should the gardener be at all the trouble and anxiety of obtaining fine and well-bloomed bunches of Grapes, part of which are to be hidden from view? Cannot some of our great china-dish manufacturers produce something more light and elegant on which to affix bunches of Grapes? Surely something of a branch-like form could be invented with, say, four or eight branches from a centre stem; Grapes suspended from the ends of these branches, would I am sure, have a more natural and elegant appearance, and the attainment of that great point in Grape-growing—viz., securing a fine bloom, would be much more encouraged.—JOHN PERKINS, *Thornham Hall, Suffolk*.

FORTHCOMING NOVELTIES.

I HAVE no wish to be classed with weather prophets, and racing prophets, and that numerous tribe of prognosticators and clairvoyants who are very bold in their assertions generally, but would rather not be held to any particular utterance that may test their powers too closely. There are always little disturbing causes, as Admiral Fitzroy calls them—little ifs, which, inconsiderable as they seem to be, do most marvellously interfere with all our calculations; and even when we have the apparent safe ground of past experience to guide us, make them not to be depended upon. Of this a trifling instance occurred to me only yesterday. Amongst the *Verbenas* I received last year from many quarters, there was a continental one named *l'Avenir de Billaut*, which struck me as being particularly worthy of general cultivation. This opinion was shared by my friend and neighbour, Mr. Banks, of Sholden, to whom I gave some cuttings, as he was anxious to grow it for seedling from. He has this spring several plants of it, and they have sent up the most miserable trusses possible, and in its present state no one would desire to grow it. But this, again, may be an exceptional state, and it may by-and-by come to its former fine condition. It is an instance, however, of the extreme difficulty of forming decided opinions, especially on yearling flowers, and ought to moderate both our praise and censure.

No. 763.—VOL. XXIX., OLD SERIES.

As I have mentioned VERBENAS, it may be as well to say a few words on the many candidates for public favour appearing this spring from various parts, and this notwithstanding that it was said that we were not to see so many novelties as usual this year. From north, south, east, and west they come. Suffolk, Norfolk, Dorsetshire, Kent, Leicestershire, Sussex, all send their quota; and this not single examples, but whole collections, many of which are unknown as yet beyond the limits of the place where they were raised. At present, then, we must only take the raisers' description, and he must be a very calm and unprejudiced man who can take a just view of his own children, can see their defects, and moderately praise their excellencies. We must wait for time to prove whether their descriptions are overdrawn or not. Amongst the lot let out by Messrs. Low & Son, and raised by Mr. Miller, of Upway (the raiser of Foxhunter), there will be found, if I mistake not, some flowers of real merit. Ruby and Rosalie are novel in their colour, besides being large, and of a good habit of growth. Purple Emperor, too, when I saw it, looked well, and was the best of a large number of the same shade of colour, all the others having been discarded.

Messrs. E. G. Henderson & Son advertise several very desirable sorts, amongst which is White Lady, stated to be far superior to Mrs. Holford, more free in flowering, and much purer in colour. This will be a most decided acquisition. They also announce other bedding varieties. The distinction between bedding and exhibition sorts ought always to be kept in view. A bedding variety ought to be short-jointed in its habit, and free in flowering, and should be entirely of one colour. If straggling the result is, that the centre of the plant is bare, and the extremities only furnished with bloom—a very ugly thing in a bed; and when there is a large yellow or white eye it detracts from that uniformity of tint which is absolutely necessary for effect. Of course, where a flower is to be cut and placed in a stand the case is entirely altered, although we think that a mixture of the one-coloured varieties with the auricula-looking sorts is even there desirable.

Mr. Charles Turner lets out this year some of Mr. Perry's seedlings of the same strain as his former fine exhibition varieties. A new white, too, he announces to us under the title of Grand Boule de Neige, from the west of England. This, too, is declared to be very fine. There is also another White Lady from Mr. Knight, of Battle, said to be very good. Of Lord Leigh sent out by Messrs. Perkins & Co., of Coventry, it is unnecessary to speak. They have exhibited it at the spring shows in considerable quantity, so that many of the flower-loving public have had a good opportunity of seeing it. It is of the Foxhunter style of flower, and very fine. Downie & Co.'s Lord Craven, promises to be a good bedding variety, as it is said to be of the style of Purple King, larger and fuller, and lighter in colour. I saw but one truss of it last season. Of the other collections I know nothing; but of this there can be no question, that if they are really as meritorious as the raisers consider them to be, we shall hear something more of them by-and-by. From the Continent, too, several are announced, but we have learned to be very cautious in our admiration of the importations from France and Germany. They see things with such a roseate hue, that it is oftentimes hard to think their opinion of what is *superbe, magnifique, charmante*, &c., agrees with what we think to be good; and few really good Verbenas have come to us from thence during the last two or three years.

There is every encouragement to raisers of seedlings to cry "Forward." We want many colours for bedding purposes—blues, whites, pinks, &c., and I hope that we shall this year see much progress. There is so widespread a love for flowers now that a really good thing is sure to be successful, and there is such opportunity of judging of the various productions, that no power exists now of pooh-poohing what is really valuable.—D., Deal.

LADY GARDENERS.

I NOTICED in your Number of April 28th the remarks of Mr. Bass, of Burton-on-Trent, upon the subject of orchard-houses. Like a good kind husband, he gives his wife the whole credit of his success in growing fruit trees in pots. And let me observe, how often do we see lady gardeners excel in the cultivation and arrangement of flowers when they give it their attention.

Some of your readers, no doubt, have visited Richmond during the summer months, and may, perhaps, have noticed a good-sized brick house on the other side the river. Now, this house

is occupied by Mr. Justice Halliburton—the "Sam Slick" of literary notoriety.

I paid a visit to these gardens about two years since on the occasion of a fancy fair given for some charitable purpose, and never do I remember to have seen bedding done so well, or so choice a collection of plants brought together in a place of so limited an extent. I was given to understand by a florist of some celebrity, who was present, that the arrangement of the beds and collecting the plants were in the hands of the lady occupier herself.

Their taste for the harmonising of colours I consider natural in all women of refined education, only unfortunately most of them display their taste in decorating themselves more than in ornamenting their gardens.

But if ladies were to follow gardening more usually than they are apt to do, how much oftener we should see the cheek resemble the Rose in place of the Lily; and how soon, also, we should perceive the lighter tints made use of in decorating the inside of the bonnets. They would soon be aware that glaring colouring was not suited to their complexions so well as the more subdued shades.

Moreover, God has given us health that we may enjoy the blessings He sends, and depend upon it, that where a lady gardener resides it is there the physician's carriage seldom stops. —A FRIEND TO FLORICULTURE.

A CHAPTER ON HERBS.

WE are told that a garden of herbs was what the Israelitish king of old intended to have made of his neighbour's vineyard which he coveted; though whether he eventually turned it into that purpose after he had so unscrupulously obtained possession we are not informed, neither are we told the description of herbs in use at that early time. There is, nevertheless, reason to believe that the list was far from being a meagre one, as it is probable some plants disregarded by us were in favour at that time, and even the term "herb" is not fully understood at the present day; for I remember not long ago, that the Judges at a horticultural show (myself being one of them), were called in question for awarding a prize for the best collection of herbs to one in which there was a bunch of Rosemary. A cottager called us to order, insisting that the collection in question ought to have been disqualified, Rosemary being more a shrub than an herb. Without, however, entering upon this knotty point, I will take the liberty of including such plants as this in our present category of herbs, which, in fact, is understood to comprehend most plants more or less scented, and used in some culinary way, or in some other manner which renders it advisable to cultivate them, more or less extensively, as they may happen to be wanted. It will not, however, be necessary to go into the details of every individual plant, but it will be sufficient to arrange them in groups, so that the treatment of one may in a great measure suffice for others in its class.

ANNUAL HERBS.—Basil, Sweet Marjoram, Summer Savory, Chervil, Borage, and others, are in ordinary use, and all more or less ripen seed and require resowing year after year. The first three are better sown in a pan or slight hotbed, and afterwards planted out in May. Chervil, being less delicate, is seldom treated to such indulgence; and Borage frequently ripens its seeds and sows itself in much the same hardy manner that Mignonette does in other places. This is also a nearer approach to a perennial, or, at least, a biennial, and in some districts is rather a favourite with those having bees. Its use dates back a very long time, and, after experiencing a long period of neglect, is likely to become fashionable again.

There are several other plants in more or less repute that might be added to this class, as Caraway, Purslane, Coriander, Marigold, Ice Plant, and it may be Nasturtium, and even Tomatoes; but these last-named plants deserve to be noticed in a separate article: therefore, I will pass on to another and much more important section of garden herbs, which is both numerous, and some of them highly useful.

PERENNIAL HERBS.—Of this class we have several which a botanist would not willingly call herbs, as some of them contain hard woody matter, which does not die down in winter, as Hyssop, Sage, Winter Savory, Lavender, as well as Rosemary, previously mentioned. All these may be classed as evergreen shrubs of low growth. But it is not the purpose here to raise that question; they are all regarded as herbs, and form important

items in the herb-border or garden. Their treatment is all much the same; they are all propagated by cuttings, which, if put in during damp weather in early summer, strike root freely.

Sage is, perhaps, the most delicate of this class, and requires to be grown on dry ground. In very cold and exposed situations in the far north it is liable to be out off in winter. Dry, gravelly, or stony ground seems to suit it best; and whether it be sheltered or not, it is always advisable to make new plantations every year, as the old plants are liable to die-off at the collar. Hyssop is more hardy, but less used, as likewise is winter Savory. Lavender may last four or five years perhaps, but seldom longer. This, too, likes a dry gravelly soil, as passengers travelling on the Great Northern Railway may have inferred from observing the fields of it near Biggleswade and elsewhere, and which when in flower sent the neighbourhood with the odour, and rival the best flower-bed in the parterre for colour. Thyme also possesses a hard woody stem, which lasts as long as the plant lives, which may be regarded as three years, perhaps—certainly not more in general. This plant, however, seeds and reproduces itself abundantly, and is very accommodating as to situation; nevertheless, it prefers a dry one, and when grown in such its aromatic principle is no doubt stronger, and, in fact, this is the case in almost everything so grown.

Differing from the above in the woody principle is Fennel, which I believe thrives best on the rocky promontories by the seashore. Its absence in early spring is scarcely less regretted than that of Parsley when a hard winter has told upon it. It is, however, a true herbaceous perennial; and but for the severities of a long winter, and the unsuitableness of certain situations, its duration may extend for very many years. On stiff wet soils it is, nevertheless, liable to die-off after seeding, in which case I have known some wild place amongst the shrubs had to be sought over for some plant that had accidentally been carried there, and nestled itself amongst the claws of the tree it had taken shelter under, and which had braved the winter by being less gluttonously fed. Tansy is also a herb of somewhat similar habit, only requiring a stiffer soil and moister place; and while mentioning these two plants, I may point them out as possessing foliage of as great beauty as any Fern we know of.

Angelica also likes a stiff soil, while Tarragon must be humoured with one of a contrary description, or there is a chance of losing it, although it is far from being a tender plant. Rue attains the character of a shrub; and some cottagers, anxious to cultivate it for sale, have grown it advantageously against a wall to the height of a dozen feet or more, cutting off the front breastwood every year. Rosemary, before alluded to, may be treated in like manner, dry situations suiting them both. Opposed to both these in habit, and in general utility second to none, is Mint, which delights in a rich damp situation, but requires replanting every two or three years at farthest. A slight covering of fresh soil or leaf mould in winter is good practice. Lemon Thyme is of much longer duration, but require a drier place. I am far from certain whether Pennyroyal likes a dry or damp situation; most likely a medium one suits it best, as also Camomile, which, however, requires replanting every second year, or even every year, and that, too, upon fresh ground, as, in fact, all herbs ought to be planted. The flowers of double Camomile have been in great repute for some purposes for a long time, but whether the double contains the useful principle in greater abundance than the single is more than I can learn. A bed of Camomile, however, is always an interesting object.

There are several other plants occasionally included in the herb-bed, as Burnet, Chives, Vervain, Garden Balm, and Balm of Gilead. The last-named is scarcely hardy. Garden Balm will speedily run over everything else, and is more robust than useful. One or two kinds of Sorrel are also cultivated there occasionally, but they are more in the character of salad plants than herbs in the usual sense. Some collections also contain wild plants, as Agrimony and Betony, and one or two poisonous plants not infrequently find a place here; but as the most useful and common ones have been enumerated, it remains only to describe in general terms the position the herb garden ought to have, when taken in conjunction with the positions of other plants cultivated in the kitchen garden and elsewhere.

It is too much the fashion now, when recording the usefulness of a plant, to insist on its having the best place in the ground, and by-and-by something else is brought forward with the same claim to pre-eminence. Thus, indifferent positions are rarely recommended at all, although we all know places of that kind abound alike in the garden of the prince and in that of the

peasant, and it would be wrong to assign everything the first place in the garden. Useful as are the greater number of herbs mentioned in the above list, it is nevertheless true that other things in the list of every-day necessities are of more consequence, so that the herbs must give place to their more useful brethren. An outside border in many gardens, called the slip, will in general do for the herbs; taking care, wherever they are planted, that those in most esteem have the best place, that the proportion of those most wanted be the largest, and that those kept merely to meet any sudden demand may be in such small quantities and in the least favourable situations that their supposed claims to notice may entitle them to. As regards those occupying the more prominent position, some little regard might be had so as to give them as nearly as possible the different soils they require in order to succeed well.

Generally speaking, a medium soil suits all, but some require a little more sun than others; and some, as Mint and Pennyroyal, do tolerably well in the shade; while Sage deserves one of the best places at command, as likewise does Tarragon.

The rotation of cropping is also as necessary here as elsewhere; and a due regard to propagating at the right season such plants as want it, will do much to maintain the uniform neatness of the cropping that is advisable everywhere. Though the herb department is less really useful in supplying the table with the materials necessary to fill the dishes, it is to the botanist and lover of plants a place of more interest, the number of species cultivated being greater; and differing as they do in many respects from each other, and from those cultivated elsewhere, who, then, can say that the "garden of herbs" is not deserving of more attention than it often receives? And when neatly arranged it may be kept in a manner that would render it a fit connecting link between the kitchen garden and dressed grounds, and an interesting feature in an establishment, to which company might be invited in order to study the various purposes in social economy to which the many interesting plants there collected are applied.

J. ROBSON.

ORCHARD-HOUSE TREES.

"I do not like thee, 'R., of S.,'
The reason why I cannot guess,
But yet I really must confess
I do not like thee, 'R., of S.,'
I like thee better 'D., of Deal,'
And think you are a clever 'chiel.'"

As the controversy on orchard-house trees has now reached a new phase by the introduction of both poetry, prose, and doggerel by the combatants on each side, will you kindly allow an old gardener to give in your pages his notions on the subject? I believe that both Mr. Robson and Mr. Keane are right in all they advance respecting the cultivation of orchard-house trees, and that it is not possible to have fruit so large and fine in pots as on planted-out trees in the borders of houses or walls. At the same time, Mr. Rivers and Mr. Pearson deserve credit for the fairness and pertinacity they show in defending their hobby when attacked. Orchard-houses when understood and well managed are useful structures in such a variable climate as ours, and to the amateur and gardener who have only limited means, they are a source of great satisfaction if not of profit. On this precious morning (the 1st of May), the thermometer denoted 6° of frost in the locality from which I write, and Apricots on the walls where unprotected are frozen as black as one's hat, although they are nearly as large as black-bird's eggs. Now, the orchard-house pot-tree-grower knows that his fruit is safe in such seasons, and so far he has a great advantage. Some ill-natured cultivators may insinuate that it is greatly to the interest of Mr. Rivers and Mr. Pearson, who are growers for sale of fruit trees in pots, to puff up their productions; but as they invite all interested to see them and taste and try, I do not see what they can do more. One thing I do know is, that until the management of orchard-houses is better understood, the sale of pot-fruit trees will be greatly increased, for the murder of these by bad ventilation and houses wrongly constructed as to the heating, is greatly on the increase.

I now mean to try and break a lance with the "brave and faithful knight, 'R., of S.,' of orchard-house celebrity." In his earnest endeavour to cry up all the uses and advantages of orchard-houses, I think he tries to prove too much, and is like the great man in the play—

"I am Sir Oracle,
Let no dog bark at me."

His attack on Mr. Robson, Mr. Keane, and all practical gardeners who do not subscribe to his notions on orchard-houses, by declaring that their "walls have enclosed their gardens and their minds," is rich in the extreme.

Mr. Keane may not, perhaps, be able to inform "R., of S.," how many pamphlets were published on Polmaise heating and coiling Vines, and what success they had. It is, however, satisfactory to know, that those systems when first promulgated were successfully exposed by practical men.

As "R., of S.," winds up with a scrap of poetry, I shall do the same with a couplet written by a famous hand at composing doggerel rhymes—

"Whene'er you write on potted trees,
No 'Keane' remarks make, if you please."

—P., of Q.

OLD VINES VIGOROUS BUT UNFRUITFUL.

I HAVE an old-fashioned vinery heated with a flue and planted with Black Hamburg Vines (now very old), and for years past I have had a capital crop of Grapes. The winter before last I made a hotbed with stable-dung in the vinery, but it was too powerful for the Vines. I was obliged to cut them down to the bottom of the vinery. They then broke and made capital wood to the top of the house. I gave plenty of air and the wood became quite ripe and looked in first-rate condition; those who saw them said I should be sure of a good crop this season. However, I am greatly surprised and disappointed to find I have only a very few bunches at the top of the vinery, and all those gone, or going, blind.

The vinery has been kept at a regular heat, not above 65°, with air occasionally. The Vines are making first-rate wood this season, except one shoot that is about 2½ feet long in the middle of the vinery, and the foliage is all going like the leaves enclosed. I have discontinued fire heat since I found out I should have no Grapes.—H. H. C.

[I have glanced over your case and should have liked your statement to have been more explicit as to time of firing the vinery; and as to the leaves sent, if they belong exclusively to the weak Vine. If so, lose no time in having it out at once. It is smothered with fungal spots, the result of unhealthy root-action; and I am greatly deceived, though the leaves are much dried, if there is not also an incipency of the dreaded mildew, and the plan you are now adopting of giving air occasionally and shutting off the fires is the best means for causing it to spread all over the house.

Now, first, it would be interesting to know when you put into the house the stable-dung that was too powerful for the Vines. Of course, if you took dung that was rank and fresh from the stables after the Vines broke, then I can conceive how the Vines were injured; but I cannot see how they could have been so injured by a mere hotbed if the manure was sweet, as I have seen many such hotbeds in houses. Neither do I see how the Vines could have been injured by rank manure being brought in when they were in a state of rest, as though I have no opportunity of doing such a thing now, I have had a vinery such a mass of pungent steam for three weeks that you could scarcely see your finger at an arm's length; but then care was taken to have the huge heap sweet enough for Cucumbers before the Vines broke, and care also was taken to keep the sweltering hot heap at a respectable distance from the stems of the Vines. I know successful cases of this mode of using unfermented litter, and I have known of cases in which there was mischief done from being too venturesome and keeping the houses too close, and if "H. H. C." has no particular reasons for the contrary, it would be instructive to know how the mischief was done, as I have a strong belief that a failure rightly used is quite as instructive as a success, only it requires a little more moral courage to let all the causes of a failure be known—that is to say, if we do know them; for the most corroding thing is to find the failure and be at sea wholly as to the causes.

I had a note the other day about Vines cut over a few inches below the soil, and because the proceeding has next to failed, without telling me anything of the plans adopted I received a genteel hint that I must have had wonderful magnifying spectacles on when I saw the Vines at Woodstock. Fortunately for my own eyesight, I received by the same post the simple statement that these Vines so cut over seem to be the best this season at Woodstock. Now, the plans adopted in the case of failure would be instructive, and as no one can describe a case

of success so well as the manipulator, I trust that when he has time Mr. McDonald will himself tell us the particulars of his treatment of those Vine-stems which he so unceremoniously sawed across. "H. H. C." would also be doing good in telling us the why and the how he injured his Vines.

Second, I should also have liked, as already stated, to have known the time when the Vines were injured, as then we would have been more sure of the cause of the want of crop this season, which I certainly attribute to a want of ripeness in the strong wood made last season. Did I know that the Vines broke afresh—say in March, or later, that the fires were left off early, and air occasionally given, then I would be certain that I am right in my surmises. I am more convinced of this from the fact of the Vines being very old, as in that case unless the border is flagged or concreted, the roots or part of them would be apt to run deep, and thus be more likely to produce luxuriant rather than well-ripened wood. This extra-luxuriance would be kept in check so long as there was a good regular crop of fruit, which of itself would absorb so much of that vigour, and leave the less for mere wood development. In such circumstances I should have given air freely during the day, left air on in smaller proportion all night, except in very cold nights, and I would have used fire heat, unless when not wanted by the heat of the weather, until the wood was as hard as oak, and the leaves began to turn yellow; and the high temperature and the dry atmosphere would evaporate the mere watery particles from the sap of the wood, and make every bud left fruitful. If I am at all right in my conclusions, I would adopt exactly the same course now, preparatory for next season, as a cool temperature and a close moist atmosphere will be apt, unless the summer and autumn are bright, to produce wood too unripe to be fruitful, with the chance of mildew and other evils in addition. But, of course, I may be wrong in my conjectures, but I think they are rather likely to be right.—R. FISH.]

A COTTAGE GARDEN AND ITS OLD-FASHIONED FLOWERS—DERBYSHIRE.

THREE fragrant Roses, white and red,
And Mint and Lad's-love grew,
And Lillies with their petals white,
And spikes of Speedwell blue;
Carnations, Pinks, and Gilliflowers,
The purple Columbine,
And Honeysuckles round the porch
Their trailing tendrils twine.

Dear homely flowers! whose very names
A fragrance seem to yield!
Ye mind me of my childhood's home,
A cottage half conceal'd
'Mid Fir trees dark, and Poplars tall,
Where now a stranger dwells,
And playmates' names, to memory dear,
The moss-grown tombstone tells.

I love ye better far than all
The modern flowers so rare—
The glaring, gaudy, scentless things
That deck the gay parterre.
I love the Primrose in the wood,
The blushing Dog Rose wild.
I love ye all the more because
I lov'd ye when a child;

For well do I remember how
(A long, long time ago),
I wander'd forth a thoughtless boy
Where yellow Cowslips grow;
With meadow-flowers of brightest hue
I wove a garland gay,
And blew the Dandelion seeds
To tell the hour of day.

Thus fancy roams! and o'er me steals
A vision bright and clear.
A mother's smile I seem to see,
A sister's laugh to hear.
The springtime comes, and summer flowers
Bloom brightly as of yore;
But sister's laugh and mother's smile
Will come again no more.

Glossop.

C. DANIEL.

THE BIRMINGHAM ROSE SHOW.—Our readers will perceive, on reference to an advertisement appearing in another column, that Thursday and Friday, the 16th and 17th of July, are the days fixed for holding the next Show. It is also announced that the prize list and regulations are now ready, and may be had on application to the Secretary.

THE CALABAR BEAN.

I AM very anxious to obtain the Calabar Bean—a vegetable substance just brought before the notice of our profession, and likely to prove of the greatest value: can you give me any information respecting it?—AN HOSPITAL SURGEON.

[The botanical name of the plant which yields the Calabar Bean, or Ordeal Bean of Old Calabar, as it is usually called, is *Physostigma venenosum* (Balfour), a large leguminous climber. Plants of it were raised some years ago in the Botanic Gardens at Kew and Edinburgh; but those at the former have since been lost. We have never heard of its flowering in this country, and do not think it is a plant likely to be cultivated in our hot-houses for its seeds.

The Bean has not yet, so far as we are aware, become an article of commerce; but we believe that it is occasionally brought to the drug markets as a curiosity. We recommend you to apply to Messrs. Allen, Hanbury & Co., of Plough Court, Lombard Street, who are likely persons to possess it.

The current Number of the "Journal of the Pharmaceutical Society" contains a notice of its application as an ophthalmic agent; and further particulars regarding its singular properties are to be found in vol. xiv. of the same work.]

ROYAL HORTICULTURAL SOCIETY.

MAY 5TH.

EXHIBITION OF SCULPTURE.—This is now to be seen at the Kensington Gardens. In the conservatory the statues are very effective, and so are the large groups on the turf before its front. The ranges of busts, &c., in the arcades are not so satisfactory. For instance, the busts are in groups of three, and we observe a very beautiful head of our Saviour placed between busts of Sir Duncan McDougal and Lord Chancellor Truro. There is something incongruous in this. The head of our Saviour on a somewhat higher pedestal, between two such figures as "Purity" and "The Peri," would have seemed to us a more harmonious association.

There are some beautiful specimens of our native sculptors' art, and they are well worthy of inspection; and so is the very artistic arrangement of the conservatory-beds.

FLORAL COMMITTEE.—The Committee held a meeting this day to examine new plants, florists' flowers, &c. Several interesting subjects were brought before them, and the following received their respective awards:—Mr. Standish sent two new handsome Clematises from Japan, one of which produced large, double, globose, creamy white flowers, about 4 inches in diameter, resembling a fully-expanded rose, with a very delicate perfume, the most superb variety yet seen. The other Clematis has a large, single, deep purple flower, which, although not so perfect in form as some other varieties in cultivation, is decidedly an acquisition. Both of these plants were awarded a first-class certificate.

Mr. Wm. Paul exhibited a flower of a new Hybrid Perpetual Rose Lord Macaulay, with remarkably handsome foliage, and of great merit. A first-class certificate was awarded. Messrs. Veitch sent several interesting new plants, among them *Cassiope fastigiata*, a hardy plant resembling the *Ericas* both in habit and flower; *Ourisia Pearcei*, also a hardy plant of dwarf habit, with bright crimson flowers in form resembling the *Pentstemons*; *Steneogastera* sp., an interesting plant bearing white terminal clusters of flowers, well suited for a specimen plant; *Sarmienta repens*, a very pretty flowering plant with bright red flowers; and *Rhododendron Picotee rosea*, one of the handsomest early-flowering varieties, with deep purplish-carmine intensely spotted flowers, and very free blooming. These each received a first-class certificate. *Browallia* sp., which had been exhibited at a previous meeting, from its improved appearance and the exquisite specimen shown had a second-class certificate.

Mr. Bull sent a very interesting and new form of *Athyrium Filix-femina*, which was renamed *sagittatum* from the form of its fronds—one of the most interesting of the endless forms of this British Fern; also *Mimulus Marvel*, a seedling hybrid between the old *Mimulus Gaiety* and Mr. Veitch's *Mimulus cupreus*. We cannot speak too highly of the result of this cross. A first-class certificate was awarded to this and the *Athyrium*.

Mr. Batley, Rugby, sent a box of cut Roses, which received a special certificate.

Mr. Sherratt, gardener to J. Bateman, Esq., sent specimens of six varieties of Moutan Pæonies, of first-rate quality, and of which the pure white were much admired; and with them a handsome spike of *Cœlogyne pandurata*, to which a special certificate was awarded.

Mr. Treen, Rugby, sent a box of cut Roses in very fine condition. Among them were some remarkable specimens of Tea Roses, particularly of our old favourite *Devoniensis*. A special certificate was awarded them.

Many other plants were placed before the Committee. Mr. Kinghorn sent two Azaleas—a double white, with small, compact, but greenish flowers; also a seedling resembling *Criterion*. Mr. Earley, of Digswell, sent a specimen of *Adiantum macrophyllum*, also *Athyrium informe*. Mr. Standish, a small Japanese plant, *Rhaphiopsis elegans*, very promising, and when again exhibited it will doubtless receive a high award. Mr. Watson, of St. Albans, sent four seedling *Dracenas*, one of which was named *Veitchii*, but not differing from other well-known varieties. Messrs. Veitch sent two species of *Scutellaria*, a rose and a white coloured variety; *Calceolaria punctata*, a novel form of this family; and *Rhododendron* Mrs. Buller; *Ourisia coccinea*, much surpassed by *Ourisia Pearcei*; and Mr. Treen, Rugby, cut specimens of *Verbenas*, among them a fine seedling Dr. Temple. Mr. Bull sent six seedling *Zonale Pelargoniums*, among them *Spark* and *Radiancy*, promising kinds; also a *Petunia* The Bride, and *Thuja occidentalis globosa*; and Mr. Watson, a seedling *Zonale Pelargonium* *Advancer*, very similar to Mrs. Milford.

FRUIT COMMITTEE.—Mr. Nash in the chair. Prizes were offered for the best three dishes of dessert Apples, the first of which were obtained by Mr. Hall, gardener to Captain Tyrrell, Fordhook, Ealing, with *Bess Pool*, *Golden Russet*, and *Cluster Golden Pippin*; and the second by Mr. Green, gardener to Mrs. Honeywood, Mark's Hall, Kelvedon, with very fine specimens of *Cockle Pippin*, *Ashmead's Kernel*, and an unknown and worthless variety.

A seedling Melon called *Golden Gem* was exhibited by Mr. Rodgers, gardener to J. Noble, Esq., Taplow. Its great merit is its earliness, and it will no doubt prove a valuable sort; but the fruit had been too long cut, and the flavour was passed. In Cherries, Mr. Freeman, gardener to the Earl of Derby, Knowsley, and Mr. Slater, gardener to the Earl of Cawdor, Stackpole, Pembroke, both sent fine dishes; but as in both instances it was desired by the exhibitors that the fruit was not to be tasted, no award was made. Exhibitors should bear in mind that at the Fruit Committee meetings it is essential that all fruit should be tasted, and that every member present should partake of it.

Mr. Thomson, of Archerfield, sent a bunch of the *Archerfield Early Muscat* all but ripe. It required about another week to be perfectly so. The Committee considered this excellent variety still maintained the high character that they have always given it whenever it has been before them.

Messrs. Downie, Laird, & Laing, of Sydenham and Edinburgh, sent three fine large heads of *Broccoli*, said to be a hybrid variety; but the Committee considered it was not superior to other late varieties in cultivation.

WINTERING NIEREMBERGIA GRACILIS.

I QUITE agree with Mr. Robson in considering damp to be more fatal to this plant than a moderate degree of cold. I have never, however, seen it survive the winter out of doors, and unprotected it will not do so here, even in mild winters like the last. A number of plants that were left standing in the beds where they had flowered the preceding summer are quite dead.

For the last two winters our plan has been to winter the *Nierembergia* out of doors under a shelter of Privet hedge. A shallow trench is first dug out, in length and breadth proportioned to the stock of plants; the trench is then filled with finely-sifted coal ashes, and in this the pots (60's) containing the plants are plunged a little below the rim; a row of Spruce Fir branches is next stuck along in front of the plants, and here they remain from November till March. Since adopting this method we lose comparatively few of the plants, which cannot always be said of those wintered in cold pits and frames, the damp confined air of those structures acting most injuriously on the plants, denuding them of their leaves, save a few at the extreme tips of the shoots, and not unfrequently killing large numbers of them outright. The list of killed and wounded is thus sometimes considerable,

occasioning a serious reduction in the stock, more especially after such a mild open winter as the one just gone.

In consequence of the extreme mildness of the past winter our stock of this favourite plant is unusually fine this year; the strongest plants are, at the present time, literally covered with a profusion of their beautiful pale lilac flowers.—J. DUNN, *Harrock Hall Gardens, Wigan.*

GARDENERS' SOCIETY.

THE able communication of "G. A." on the formation of a Gardener's Company, or general society for the mutual improvement and benefit of gardeners as a body, has, doubtless, met with general approval, for there can be no real objection to the formation of such a society, nor can there be any doubt as to its feasibility. It must also be admitted, that the project is one calculated to prove greatly advantageous both to the profession and the members of it. Granted this much, I trust the subject will not be allowed easily to drop, and that the pages of *THE JOURNAL OF HORTICULTURE* will be open to a free discussion on all matters relating thereto. This I have no doubt will be the case, as the Editors have shown themselves favourable to the scheme. Nothing is more likely to elucidate the matter than a full discussion, for although the main scheme will most likely be generally approved, there are matters of detail which must and will cause some little contention before anything like an amicable arrangement can be arrived at.

For my own part I consider that any restrictions with regard to the exclusion of any particular class ought to be avoided rather than otherwise; for if a body of men are to act in concert for the benefit of all parties concerned, the main object ought to have precedence over all others, and the farther removed any mere distinction of class or grade is from the one grand object, the less consideration should it receive at the hands of those who have to frame the rules and regulations of the Society. For instance: A man may conform to all the rules laid down for admission as a professional gardener, and yet be one in name and appearance, more than from any real qualification he possesses for filling such a position beyond a good personal address, which is often a passport into situations which the possessor is in no way qualified to fill. He may be a successful exhibitor, not because he is a skilful cultivator, but because his subordinates are (for instances are not wanting where the head gardener has obtained credit for what he is no way entitled to, his right-hand man being the real manager, without whom the head gardener could do nothing), in fact, from his position he is admitted as a first-class member, while a utilitarian who has, probably, studied hard and grounded himself in the general science of gardening, is still a utilitarian: consequently he must be debarred from such privileges as fall to those of a more elevated position in the gardening world.

I simply put this in order to show that a man's position is no real guide as to his abilities or acquirements, and where the restrictions are too severe, there is a possibility of the right man being excluded from the right place.

If a society is expected to be successful, it ought to be constructed on the most liberal principles, however unpleasantly it may jar against the feelings of an educated class that others of an inferior grade are to be admitted on equal or nearly equal terms. Still to a certain extent it ought to be borne with. Some distinctions are admissible, and, perhaps, advisable; but they ought to be such as are easily surmounted; for if the society is to benefit all classes of gardeners, a large body of them, probably the most numerous, will scarcely deem it a favour to be admitted on terms that will place their so-called inferior position ever before them.

Such a Company as that referred to will, I trust, eventually be formed; and I still further hope, that the rules and regulations will be framed more with a view to benefit and satisfy all classes of a profession in itself both liberal and progressive, than with any view to show up the various grades and distinctions of its members and votaries. If this is done, the entrance fee and the subscriptions may be high or even extravagant, but they will be paid more cheerfully than if the subscriptions were low, and the great body of members had no vote and scarcely a hearing, but must submit to the dictates of the favoured few, who in consequence of paying higher subscriptions would retain the government of the whole affair.

I am at a loss to understand why "G. A." would require the subscription of employers to be so much higher than that of

others. Doubtless, the majority of them would be willing to subscribe as he intimates; but the question might be asked, What benefit are employers likely to derive in proportion to the amount of their subscriptions? True, there would be the increased facility for obtaining a competent gardener when one is required; but is this likely to occur so often as to justify the amount? Employers I believe would enter into the project willingly, not on account of the benefit derivable from it, but for the same reason that they form horticultural societies—that is, from an interest in the science and practice of horticulture.

Should employers take up the matter and thus give an impetus to the formation of a Company it would not otherwise receive, this would lay the foundation; and with the amount of entry-fees and subscriptions, as "G. A." sanguinely explains, the Society would be fixed on a popular because solvent basis. But then in whose hands should the government of the Society be retained? Certainly not entirely in the hands of employers or any other class. This, perhaps, is the most delicate part of the affair; for although every division should be fairly and equally represented, the question is, how is this to be done? I should be inclined to recommend that the subscriptions of all classes of members be pretty nearly equalised, that all should be allowed to vote freely at the election of officers, &c., and that the offices be open to all classes where men are likely to be found of competent ability to fill them, although it is evident that such are most likely to be found among the educated. Whether there are many in the gardening fraternity who are of my way of thinking in this matter I do not know; I merely give expression to my views, which are opposed to framing a society's rules with one eye directed to caste and the other to the pocket.

However inappropriate it may appear to discuss the laws of a society yet unborn, it is far from being without a purpose, for in this way some useful hints are likely to appear that may be of service to those who may have the framing of them at some future time. But then before this takes place it must be known how far the gardening world would take up the matter in right good earnest, so that were a body of men to form a nucleus they might know what support to expect. Could not every reader of *THE JOURNAL OF HORTICULTURE* who is favourable to the formation of a Company, send his name and that of as many of his friends as are also favourable, and who are willing to be enrolled as members, to the Editors, who, I doubt not, would kindly keep an account of the number, and, perhaps, make it public, so that we may all know how far the proposal of "G. A." is likely to meet with that favour it deserves?—F. CHITTY.

MRS. GAINES' PLANT SALE, SURREY LANE, BATTERSEA.

ON Monday, April 27th and three following days, the whole of the stock of plants belonging to this once-celebrated nursery, were disposed of by auction.

The sale on the whole brought very satisfactory prices, and was numerously attended by persons far and near. Messrs. F. & A. Dickson & Sons, Nurserymen, Chester, purchased some of the largest specimen Azaleas, which realised five guineas each. Miss Macpherson Grant, of Craigellachie, was also a buyer of specimen Azaleas and paid high prices. Amongst other large buyers were Mr. Bennett, gardener to G. S. Foljambe, Esq., Worsop; Mr. Pullenger, gardener to — Rust, Esq., Mitcham, who purchased the Rhododendron Aureum, for five guineas, so many times exhibited by the late Mr. Gaines; also, many other valuable lots. A gentleman from Newcastle was also a large buyer. Thus it will be seen the lots are well scattered about the country.

It is with feelings of regret that we should have to record the last of this celebrated nursery. Neither would it be just to let it pass away without a remark. For many years this nursery in the cultivation of florists' flowers stood almost unrivalled. The Auricula, Pansy, Dahlia, Calceolaria, and Geranium have each been cultivated there to the highest degree of perfection, and no person in the flower market ever had more respect shown her than the late Mrs. Nancy Gaines, who for a period of exactly fifty years was attendant at Covent Garden Market, and whose name for perseverance and uprightness will be remembered for many years yet to come. The same respect is due to Mrs. Gaines the present occupier of the nursery, who may be termed a model obliging woman of business.

Of late the nursery has been used for marketing plants. The

late Mr. Gaines, finding he was so surrounded with new buildings that specimens could not be successfully grown for exhibition, turned his attention to cultivate almost entirely for market. Thus we found the class of plants very different to what we should have seen sixteen years since.—E. BENNETT, *Osberton*.

NEW BOOK.

A Practical Treatise on the Cultivation of the Grape Vine. By William Thomson, Gardener to his Grace the Duke of Buccleuch, Dalkeith Park. Third Edition. Blackwood & Sons, Edinburgh and London.

It is sufficient to say of this admirable work that it has already reached a third edition, and in this edition the author has made such alterations and additions as another season has added to his already large stock of experience.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

ALOCASIA LOWII (Mr. Low's *Alocasia*).—*Nat. ord.*, Aroidæ. *Linn.*, Monoclea Monandria. Introduced from Borneo by Messrs. Low & Son, Clapton Nursery. Flowered in a stove during January. Chiefly decorative by its strikingly white ribbed leaves, rendering it "unquestionably one of the most desirable of the *Alocasias* for cultivation."—(*Botanical Mag.*, t. 5376.)

SAXIFRAGA FORTUNEI (Mr. Fortune's Saxifrage).—Introduced from Japan by Mr. Fortune, and cultivated at Mr. Standish's Nursery, Bagshot. Flowers white.—(*Ibid.*, t. 5377.)

HEMANTHUS NATALENSIS (Natal *Hemanthus*).—*Nat. ord.*, Amaryllidaceæ. *Linn.*, Hexandria Monogynia. "A charming greenhouse plant," discovered by the late Dr. Pappe, at Natal, and blossoming in the Cape-bulb house at Kew in February. Bracts rich crimson-purple; stamens and styles bright orange, sheathing scales beautifully coloured and dotted with crimson.—(*Ibid.*, t. 5378.)

SCILLA NATALENSIS (Natal Squill).—*Nat. ord.*, Liliaceæ. *Linn.*, Hexandria Monogynia. Introduced by M. Van Houtte, from Natal. Pedicels of the same soft pale blue as the corollas.—(*Ibid.*, t. 5379.)

HETEROTROPA PARVIFLORA (Small-flowered Heterotrope).—*Nat. ord.*, Aristolochiæ. *Linn.*, Gynandria Dodecandria. Sent from Japan by H. E. Hoey, Esq. Flowers purple edged with green. Leaves dark green, marbled in the centre with a lighter green.—(*Ibid.*, t. 5380.)

IMANTOPHYLLUM MINIATUM (Orange-coloured Imantophyllum).—*Nat. ord.*, Amaryllidaceæ. *Linn.*, Hexandria Monogynia. Sent to this country from Natal by Mr. J. Backhouse, of York. Flowers orange, but white and lemon-coloured inside at the base. Desirable and easily cultivated.—(*Floral Magazine*, pl. 145.)

ROSE, FRANÇOIS LACHARME.—A French-raised flower introduced by Mr. Turner, Slough Nursery. "One of the finest flowers of last year," being "a dark Jules Margottin."—(*Ibid.*, pl. 146.)

CAMELLIA, DUCHESSE DE BEERI.—"Certainly the finest of the white Camellias grown."—(*Ibid.*, pl. 147.)

PELARGONIUMS.—Seedlings raised at Clewer Manor. *Improvement*, lower petals rich purple; upper petals maroon-blotched with purple margin. *Censor*, crimson purple. *Souvenir* has "richly-painted crimson and black lower petals, black top and bright margin."—(*Ibid.*, pl. 148.)

DELPHINIUM ALOPECUROIDES.—A double variety of Larkspur, raised by Mr. Wheeler, of Warminster, who "called it *alopeuroides*, doubtless from the close brush-like form of the principal part of the spike." It is very hardy, and propagated by division, as it never produces seed.—(*Florist and Pomologist*, ii., 57.)

PEAR, NOUVELLE FULVIE.—"Admirably portrayed by Mrs. Dix." It was raised by M. Grégoire, of Jodoigne. A melting, finely perfumed, and richly flavoured Pear. Ripe in January and February.—(*Ibid.*, 64.)

FOUNTAINS.

By H. NOEL HUMPHREYS, ESQ.

THE most highly wrought effects produced in garden architecture have been those effected by means of fountains; of this,

the well-known gardenesque waterworks of Versailles and St. Cloud are sufficient evidence.

Sir Uvedale Price says:—"With respect to fountains and statues, as they are among the most refined of all garden ornaments, so are they the most liable to be introduced with impropriety. The effect, however (especially that of water mixed with sculpture), is of the most brilliant kind. Some have asserted that fountains are unnatural; but natural *jets d'eau*, though rare, do exist, and are among the most surprising exhibitions of nature, which, in Iceland and other volcanic regions, have struck the traveller with wonder.

But though we find natural fountains in the wildest scenes of nature, it is not, however, necessary, in making artistic use of a natural law that produces a *jet d'eau*, to surround the artificial jet with the circumstances that surround it in nature, any more than it is necessary that the architect, in building with stone, should imitate in his work the rude form of the quarry from which it was taken. On the contrary, as fountains produce the best effect near buildings, and in combination with statuary, architects and sculptors like Bernini, says Sir U. Price, would not think of inquiring what were the precise forms of natural waterpouts; but knowing that water forced into the air must necessarily assume a great variety of beautiful effects, which, added to its native clearness and brilliancy, would admirably accord with the forms and colours of statues and architecture, would use it accordingly.

Nature and art are more closely allied than appears at a first glance; for all art is founded upon the development of some natural law, which Shakespeare perceived when he makes Polixenes, in the "Winter's Tale," say

"This is an art
Which does mend nature—change it, rather: but
The art is nature's self."

Under ordinary circumstances, the scenic features that surround garden fountains are such that the impression one receives on seeing water forced into the air is, that art has been employed to produce the effect: therefore, while still water finds its more appropriate locality in the lower portion of the grounds, fountains may be more properly placed in the higher levels of a garden, as their evidently artificial character seems to find its appropriate situation in a position where water would be highly desirable and ornamental, but where it could only be brought by scientific and artistic means. Here, then, the display of art, even to a degree of ostentation, becomes legitimate; and fountains of elaborate character and complicated architectural design find their most imposing station at the extremities, or centres, of elevated terraces, and places of similar character, where the gardenesque and semi-architectural character of the surrounding scene, is all in artistic harmony with them.

Very few good fountains have been as yet constructed in England; the two in Trafalgar Square—which our national *Charivari* (*Punch*), very aptly and cleverly compared to "two saucers surmounted by a bottle of ginger beer"—being signal failures; and the one erected at Brighton, though on a more ambitious scale, almost equally unsuccessful. Into the region of "art," in the treatment of fountains, we have not yet penetrated; but in simpler forms of fountains—that of a simple jet issuing at once from the level of the main water—greater success has been attained, as mere "dimension" is the great quality in this unadorned natural effect. The scale is, in fact, everything; and so far, the jet at Chatsworth is highly successful—indeed, magnificent; but all the other attempts at fountain-work, all the minor squintings, including the two celebrated "water-trees," are beneath notice; and still more worthless, in point of art, are all the fantastic failures called fountains at Alton Towers.

Modern Italy is the classic land of fountains. Long before Le Notre and his cotemporaries and collaborateurs constructed the celebrated waterworks of Versailles, the magnificent fountains of the Villa d'Este, and those of the Villa Aldobrandini, were well known and justly celebrated works, especially the building called the "Saloon of the Winds," where water is made to produce rushing sounds characteristic of the four winds, the personifying deities of which form sculptural groups, among which the play of waters has a very grand effect. Still more elaborate is the work of Giacomo della Porta, the celebrated Mount Parnassus, with the deities playing on different musical instruments, the sounds of which are imitated by the water in a manner, which, if not entirely successful, is yet sufficiently approaching the desired effect to be very astonishing. These wonders of the villas of the Sabine Hills, in the region of Tivoli and Frascati,

are, however, among the over-wrought effects of hydraulic science and art. More simple, and more artistically grand, are some of the fountains of Rome; that, for instance, which introduces the *acqua Paola* to Rome—a supply named after Pope Paul V., the founder of the Borghesi family, who repaired one of the ancient aqueducts, and so united a magnificent stream of water once more to Rome, after centuries of severation, in consequence of ruinous portions of the aqueduct allowing the stream to waste itself uselessly on the Campagna. To usher this restored supply of the precious element into the “Eternal City” with due “pomp and circumstance,” a magnificent architectural composition was erected on the slope of the Janiculan Hill, between the columns of which three grandly designed apertures appear, from which three torrents, for no other term will sufficiently express the bulk of water—fall with a deafening sound, amid a cloud

of spray, into three gigantic *tazze*, from which conduits carry the water to supply many of the greater, and an endless number of the lesser fountains of Rome. The fountains on the Piazza San’ Pietro are, perhaps, the finest detached specimens of purely decorative fountains in existence. They are the work of

and imposing. These, with the great fountain of Trevi, have afforded Madame de Staël subject for some of her most eloquent, descriptive passages in her admirable novel, “*Corinne, ou l’Italie*.”

No. 1 is a small, and, of course, inadequate representation of one of the fountains of St. Peter’s. No. 2, that of Palazzo Farnese; and No. 3, another grand and simple example of the fountains of Rome—that of the Court of the Belvidere.

In these fountains the abundance of water always forms the grandest feature—a mere squirt is but a caricature in comparison, for, to cite a passage recently quoted by Emerson in his “*Representative Men*,” “A single drop of seawater possesses all the chemical properties of the great ocean of which it is a part, but it is incapable of representing the phenomenon of a

storm.” Thus we see that magnitude must inevitably form a great element in the sublime, and that dimension, as well as design, are points to be considered in the construction of objects intended to produce a certain effect of grandeur.

In places, however, where an enormous supply of water would

No. 2.—Fountains of the Palazzo Farnese.

No. 3.—Fountain of the Vatican, in the Court of the Belvidere.

Carlo Maderno; and such is the magnificent character of this simple design—the quantity of water thrown up, and falling in clouds of spray, in which, at a certain hour, one or more rainbows are distinctly seen—that, even immediately in front of St. Peter’s, one of the largest and most imposing buildings in the world, their effect so far from being insignificant, is most grand

and imposing. These, with the great fountain of Trevi, have afforded Madame de Staël subject for some of her most eloquent, descriptive passages in her admirable novel, “*Corinne, ou l’Italie*.”

possible form being the one in which the action of the fountain should be commonly seen.

My examples from the fountains of Rome have not been selected to exhibit the vast scale and magnificence of the greatest of those works, many of which occupy great space; being, in fact, complicated sculptural tableaux, in which a great number

of statues are required to complete the composition. I have rather selected such examples as might be applicable to practical purposes.

“ — dans l'air s'enflammant au feu d'un soleil pur,
Pleuvor en gouttes d'or, d'émeraude, et d'azur.”

PHILODENDRON SIMSII.

Nat. ord., Araceæ, ? Caladiææ. Linn., Monœcia Triandria.

GENERIC CHARACTER.—*PHILODENDRON*, Schott.—Spathe convolute at the base, straight, closed after flowering. Spadix continuously androgynous; rudimentary reproductive organs below the stamens; no sterile appendix. Anthers two-celled, distinct, 2-7, placed back to back in areolæ; the cells hidden within the connective, open at the apex. Ovaries many, crowded, free, 5-15 celled. Ovules several, ascending from the central angle of the cells, orthotropous; style very short or wanting; stigma capitate, truncate, or with imperfect radiating lobes. Berries distinct, many-seeded.—(Endl. Gen. Plant.)

P. SIMSII.—*Kunth*.—Caulicent; rooting; leaves shining cordate-sagittate, acute; petioles roundish, slightly flattened on the upper side; spadix slightly contracted below the middle, then tapering gradually to a point; spathe cylindrically hood-shaped above, constricted in the middle, inflated below, a little longer than the spadix.

SYNONYMY.—*Philodendron Simsii*.—*Kunth*, *Enumeratio Plant.*, iii., 48. —*Caladifolium*, Sims, in *Bot. Mag.*, t. 2643 (not of Jacquin). *C. Simsii*, *Hooker*, in *Bot. Mag.*, p. 3345.

DESCRIPTION.—A fine stove perennial. Rhizome elongated into a stem, rooting. Leaves cordate-sagittate, very large, the blade 2 feet long, shining; petiole roundish, more and more flattened on the upper side upwards, elongated (30 inches), closely marked with fine, deep-green, interrupted streaks; petiolar sheath very short. Spadix about 8 inches long, cylindrically hood-shaped, convolute at the base, contracted in the middle, and attenuated above into a fine point, white, and marked about 2 inches below the contracted portion with an oblique crimson band, shaded off above and below. Spadix nearly as long as the spathe, thickened below, slightly contracted below the middle, and tapering gradually up to the rather acute point; the first inch from the base occupied by the numerous distinct ovaries, the remainder presenting a smooth surface, with reticular lines indicating the boundaries of the groups of sterile and fertile stamens. Rudimentary staminal groups below the fertile. Stamens consisting of distinct sessile, two-celled anthers, arranged 2-7 in a polygonal group, back to back, in close contact, the cells of the anthers concealed within the connective, opening at the apex. Ovaries numerous, crowded, but free, conical, many-celled; styles almost none; stigmas capitate,

flattened on the summit, and with slightly marked radiating lobes. Ovules numerous, orthotropous, ascending from the internal angle of the cells. Berries?

HISTORY.—This plant is a native of Demerara, and is not new to our gardens. It was figured by Sims in the “Botanical Magazine,” under the name of *Caladium grandifolium*; Sir W. J. Hooker subsequently showed, in the same work, that it was not the *Arum grandifolium* of Jacquin, and named it *C. Simsii*. It belongs to the genus *Philodendron* of Schott, under which name it is included in Kunth’s “Enumeratio.” Its large, glossy, deep-green leaves, and broad crimson band in the white spathe, give it a striking appearance.—A. H.

CULTURE.—The *Philodendron* figured in our plate is a free-growing stove plant. It should be potted in rough, porous compost; and, from its large size, requires a large pot, which must be well drained. The old stems push out roots, which hang about the pot without striking into the soil, and, no doubt, contribute, like the aerial roots of Orchids, to the support of the plant. It is increased by separating the shoots which, from time to time, branch out from the old stem. The species is more curious than ornamental.—(Gardeners' Mag. of Botany.)

FRUIT TREES IN POTS.

THE subject of growing fruit trees in pots, which has been so freely discussed in the columns of THE JOURNAL OF HORTICULTURE, must, if not very instructive, have certainly proved very amusing to most of your readers. The subject I confess is interesting to me, as I have had under my care for the last few years a collection of upwards of three hundred fruit trees in pots, consisting of Peaches, Nectarines, Apricots, Plums, Cherries, and Figs.

I believe I may say that I am considered to have been tolerably successful in the cultivation of them. This season most of the trees are covered with fruit; and although some of them are not so, yet all are healthy, perfectly clean, and well-formed trees. Visitors call them magnificent trees, but visitors will sometimes be complimentary. My employers appear to like them, and I rather like them myself, and of course, I consider myself in duty bound to do all I can to cultivate them successfully; but at the same time, from what I have already said, it may be supposed that, in my own homely way, I may have come to some conclusions upon the subject. I admit that I have done so, and in as few words as possible I will state them.

I am convinced that good fruit may be and has been obtained from trees growing in pots; and I am also convinced that better fruit may be and has been obtained from trees planted out and trained in the usual way, and if time and labour be reckoned as money (which they ought to be), the fruit from trees planted out is obtained at least 100 per cent. cheaper.

I admit that a fruit tree in full bearing and growing in a flower-pot is a curious and very interesting object, and so are Mushrooms growing in flower-pots. I have seen the surface of some two or three dozen nine-inch pots completely covered with snow-white Mushrooms arranged on the floor of a dark cellar—a sight I can assure your readers worth lighting a candle to look at.—G.

[We have omitted the last paragraph in your note because, on second thoughts, we are sure you will agree with us that a mode of culture so interesting, even if not profitable, does not deserve ridicule. You have alluded to one fact on which you would oblige us by more information—growing Mushrooms in pots. We had heard of this being done, and should be glad to know more of the mode of culture pursued.—EDS. J. OF H.]

METEOROLOGICAL NOTES.

"WHAT a remarkably fine season!" is an observation we hear on all sides. Fruit trees are laden with blossom in one place; and in another we hear of it being set and the young crop swelling with unusual rapidity. There is no doubt, however, that we shall hear complaints by-and-by; and even now, in the beginning of May, the weather is too fine for some.

On all sides we hear of its being a very dry spring. Water is said to be scarce and the ground dry and hard. Three months ago the story was what a bad season it has been, so accustomed are we to run to extremes. However, taking it for granted that the early winter months were wet, they were not more so than is usual at that time; but the last three months have been unusually dry—drier than any similar period I have any record of, excepting the spring of 1853, when the rainfall was less for the winter six months than it has been this year. This will be seen by the following table, which exhibits the rainfall in inches for the winter season mentioned, commencing with the 1st of November and ending with the last day in April, as compared with the rainfall for the corresponding six months for the last eight years:—

Winter of 1855-56	rainfall, 12.40 inches.
" 1856-57	" 10.72 "
" 1857-58	" 6.93 "
" 1858-59	" 9.01 "
" 1859-60	" 17.21 "
" 1860-61	" 10.68 "
" 1861-62	" 16.32 "
" 1862-63	" 7.95 "

The wettest month during the above period was November, 1861, when 6.10 inches of rain fell; the driest was February, 1857, when only 0.27 of rain fell. Nevertheless, singular as it may appear, and probably at variance with the popular notions of long droughts and long wet periods, I have no record in the years above given of there ever having been more than fourteen consecutive days without any rain, while seventeen consecutive wet days without a dry one is the longest period of an opposite

character. I need hardly say that small, almost inappreciable quantities of rain sometimes divide long periods of dry weather, so as to leave no greater number of days without rain than is given above. Even in the month that is past, though an unusually dry one, less than three-quarters of an inch of rain falling, that was distributed over ten days, being the 4th, 7th, 8th, 11th, 12th, 16th, 22nd, 28th, 29th, and 30th.

With regard to the progress made by vegetation, the present season may be justly regarded as an early one up to the end of April, but a period of dull and cold weather will easily reduce it to the level of ordinary seasons. With me some Apple blossom was out on the 16th April, being three days later than it was in 1859; but, in general, vegetation was certainly farther advanced at the end of that month this year than it was at the same time in 1859. Asparagus, however, has been earlier in years gone by than it is this season; and, on the other hand, the fine weather sent that harbinger of spring, the cuckoo, amongst us earlier than I ever knew it. I heard it several times on the 13th, and some assert it to have been heard the day before. The other tokens of spring I need not go into, as it is with regard to the amount of rainfall that I beg to call the attention of your readers. I confess I look with some degree of alarm to the probability of wells, ponds, streams, and other sources of supply being exhausted before summer is over. Whether this may prove to be the case or not remains to be seen; certainly if these reservoirs depend on the winter's rain to feed them for this summer's work, there is much reason to fear that a deficiency will follow.

In regard to the absence of all sharp frosts, the past winter has also shown us that some of our ideas were erroneous about the tillage and pulverisation of the soil, for in many instances where the ground was dug up in time and received the benefit of the dry weather in February and March, it works pretty well—better than it sometimes does after frost when the latter is followed by a season of wet weather. Of the well-doing or otherwise of crops it is premature to speak; but at present all is hope, and in many instances the promises are flattering.

J. ROBSON.

BARBADOES POTATO.

It does not appear that this Potato has been grown to any extent for the last seventeen years. For some years before this period it was considered in this neighbourhood the finest sort in existence, one Potato being sufficient for a dish. I have made inquiries in all directions. From one quarter I was informed that 10s. were offered for a tuber. There are no knobs on the Barbadoes Potato, as stated by "Q. Q.," to exist in the varieties he mentions, and it has but very few eyes. It is an early sort, and the haulm, although branching, is not very tall. Many thanks to those who have endeavoured to throw some light upon this subject.—A. CONSTANT READER.

WHAT ARE GOOD MANNERS IN VISITING A FRIEND'S GARDEN?

I HAVE a neighbour who comes to see me several times a-year, and whose visits I have hardly grace enough to endure. He has a smattering of horticultural knowledge, and he owns a country place, which he thinks is the very pink of perfection. "Now, I want you to go around and show me your grounds." Well, while I am trying to do so, he struts loftily, and talks about his own establishment, his English gardener, and his fast horses. Am I pointing out a fine specimen of the European or Siberian Silver Fir, he breaks in, "Oh, yes, I've several like them, only bigger; the pedlar of whom I got mine said they called them Balsams down in the swamp." Show him a Delaware or Rebecca Grape, and he will admit they are tolerably good, but smaller and less fragrant than the Charter Oak and Northern Muscadine. A Japan Lily is passable, but then he has several other kinds, yellow, red, and white, lots of them! And so he runs on about his arbours, and his terraces, and his serpentine walks, and his statues of Venus and Neptune, and much other gimcrackery with which his pretentious place abounds. When he has sufficiently disparaged my place, and lauded his own, he goes home. I pray you, Mr. Editor, nappen this way some time, and bring him down from his high horse.

A friend of mine, who is a fond planter of trees, has also a thorn in his flesh. It is a lady! She looketh not well to the

ways of her household, but, neglecting her children, goeth about to talk of cats, dogs, horses, and flowers. Her mind is good, so far as it goes, but its scope is not wide. When she visits my friend, she never notices the rare trees which are his joy and pride, nor the velvet lawn, nor the antique vases, nor the fine outlooks into the surrounding scenery, which he has opened with so much artistic skill; but she begins at once to harrass him with talk about some petty detail, generally of her own experience. Now she chatters away about sowing flower-seeds, then how to cure a sick cat, how to strike cuttings, how to poultice a felon, how to save seeds; and she dwells on each point with a minuteness and long repetition, that—that “beats the Dutch.” And all this sort of talk while walking through one of the finest gardens in all this region of country! She finishes up each visit by begging a few cuttings and a few seeds, and then, with a curtsy and a bewitching smile, bids adieu.

The question now returns Mr. Editor, which is the proper way to make a horticultural visit? It strikes me I should not make it an occasion for disparaging my friend's garden and extolling my own. It is not best to waste his time, and tax his patience, by chattering away about some trivial details, or such matters as can just as well be discussed elsewhere. I should leave my garden at home when I go to visit him. Instead of pulling at his button-hole, and engrossing the time with my sage observations, I should listen to him, in a receptive state of mind, desirous to see and learn, and enjoy all I can; and, when my visit is ended, I should thank him for the pleasure he has afforded me.

And, sir, I gladly testify that I do receive such visits now and then. Some persons show at once that they appreciate what they see; instead of criticising, or making invidious comparisons, they heartily admire, and express their pleasure without stint. Others walk along more quietly, confessing their ignorance of gardening in its higher forms, but begging me to tell them the name of this and that, and the origin of the other; and they receive all that they see and hear with evident satisfaction. It is a great pleasure to receive such guests.

And, now that we are on this subject, let me add a few words more on another branch of it. The middle of the day is not a desirable time for visiting gardens; for then the light falls vertically, and the shadows of trees and shrubs are almost imperceptible. If, too, it is midsummer, the heat of noon is so intense that the visitor puffs and sweats, and feels that he is pursuing enjoyment under difficulties. Half the poetry of a garden is lost by viewing it under a broiling sun. Go, rather, in the morning, when the dew is sparkling on tree and grass, and when the birds are musical; or, go at evening, when the shadows fall aslant, when the heat has abated, and the cool air is fragrant.

[You have hit upon a suggestive theme, and painted it in life-like colours. We are sorry to say that just such ill-bred persons do own country places; but how painfully plain it is that they were not educated for them, that they are strangely out of place, that neither is fitted for the other any more than jewels are fitted to adorn animated pork. Oh that these men would learn the wisdom of silence! Few things are more painfully annoying than a visit from a man full of pompous pretension: he will neither enjoy anything himself, nor let you. No matter how well grown or beautiful your plants may be, he always has something better at home: no word of praise or commendation ever escapes his lips, be it ever so well deserved. He runs his round of stereotyped depreciation, departs, and you feel as if you had been relieved of some hateful nightmare. We can remember with satisfaction more than once having knocked the stilts from under such men, and precipitated them to their proper level. We never fail to do it when we can; for a man has no right, moral or otherwise, to be unamiable at his friend's house. The world is no better for such men, but quite the reverse. We would reason thus with them: When you enter a friend's garden do try and leave at the gate all egotism and selfishness, and resolve to please and be pleased. Remember with how much care your friend has collected the plants about him, and how much enjoyment he finds in them. Remember that they are all beautiful, some more, some less: this you cannot help feeling, though you may not acknowledge it. Remember, above all, that they are the handiwork of Infinite Goodness, and speak not contemptuously of them, even to heighten the praises of your own. If you want to hear your own plants praised, ask your friend to come and see them; and if he is barely a sensible man, with a heart alive to the propeties of life, and a nice appreciation of the beauties of nature, you will hear enough to make a reason-

able and modest man content; for how much better it is that another should praise us than that we should praise ourselves.

Having disposed of the man, what shall we do with the woman? We fear we shall have to put on a pair of soft kid gloves. The treatment in this case must be gentle and soothing. When she begins to talk about cats and dogs, tell her, as she seems to be so very fond of them, you will send her a good litter, which you must forthwith do. Send a fresh litter every time she broaches the subject, and in time she will take the hint, and carefully avoid the mention of cats and dogs in your presence. In like manner treat other inapposite subjects—for instance, when she talks about a poultice for a felon, say to her, “Well, well; but is that poultice good for the Black Knot?” You will be able to manage her in this way. Fortunately, there are only about three such women in the world; and the rest of them are such dear delightful creatures, and love flowers so fondly, flitting about among them like butterflies, sucking sweets from each, that you can well afford to bear with the three that are full of cats, and dogs, and felons, and what not.

You have a just and proper conception of what a horticultural visit ought to be. When we make such visits, we go for the purpose of learning and enjoyment, and to make our friends as happy as may be. Horticultural intercourse often is, and always might be made, a source of the purest enjoyment. There is something in horticulture that tends strongly to develope and expand man's social qualities; the only drawbacks to this are the selfishness and egotism of unregenerate human nature. What a delightful thing it is to receive a visit from one who knows the full value and beauty of your plants, and has the manliness to say so. We see you understand this perfectly. You are altogether right in regard to the best time to visit the garden. It is surprising how few think of this, and yet a whole chapter might be written about it.]—(*American Horticulturist*.)

GARDEN HELPS.

ALTHOUGH on various late occasions I have perused with great interest the numerous contributions respecting “garden helps” inserted in your valued periodical, I purposely abstained from remitting my present communication until now, because the period of the year is closely approaching when young birds of the kind desired will be easily procurable at a very moderate cost; and again I fancied a word in season the most appropriate to insure a trial among those of your readers who feel interested in such matters. Permit me to preface my remarks by stating that a walled garden is indispensable, otherwise, most probably, disappointment will ensue.

When I recall the incidents connected with the great variety of “pets” kept many years back by my late sister and self, and in respect to which it was difficult to determine which of the two felt the deeper interest in those hobbies, I believe our tame lapwings afforded us the greatest amount of pleasure and benefit, and for some six or seven years they prospered exceedingly. Our birds at the outset were casually brought to us by a country friend, and, if memory is not defective, were five in number. It is sufficient for present purposes to say that two males and a female were reared to maturity. When we first received them they were only partially feathered, but were strong healthy birds. We then fed them on the large dew-worms, expressly collected for their use, and, to increase the supply of food at the least amount of personal exertion, small strips of raw lean beef were added, although they gave a decided preference to the living worms. In a fortnight or so we turned them altogether on their own resources in the garden, and they still thrive even more so than previously—in fact, they received no particular care or attention; but it is justice to say that the quantity of snails, worms, in fact insects of every kind, they daily devoured was beyond credence.

The benefit to the damp garden we at that time occupied was of course commensurate; for, after their introduction, the crops never suffered as previously from the “slugs,” through the ravages of which our gardener said, “it was impossible to grow anything;” consequently, he at length acknowledged them as some of “his best friends,” though at the first sadly averse to their introduction. A point of considerable importance is that they never interfered, to the best of my knowledge, with any crop whatever; and taking into consideration the fact that they fed almost exclusively on insects and worms, the excrement was not as offensive to the eye as would be anticipated—so much so,

that had the premises been larger, my opinion is it would have been scarcely noticeable. They moulted into adult feather at autumn, and then became as brilliant in plumage as the lapwing when enjoying its perfect liberty. Of course they had been long previously carefully pinioned, and the outer gates of the garden had been so arranged as to close instantly after all comers.

It will be seen the difficulty of rearing was trivial, and thus some of the most beautiful and interesting objects connected with the garden were obtained with little forethought or trouble, and at an expense not worth even the mention. As winter approached we found, however, that we were compelled to find additional nutriment, particularly during frosty weather; and, to compensate for this deficiency of natural food, bread-crumbs, chopped cheese, with eggs boiled hard, served every purpose. At spring the two males were no longer sociable, and at length carried their animosity to such a point as compelled us to give the one to a friend. Strange to say, at once it proved equally tame with him as with ourselves who reared it. This particular bird fell a prey to a large tom cat, to the great annoyance of its owner, who saw the bird killed. He told me a week afterwards, somewhat gloating, the death of his bird caused Mrs. —'s cat to "evaporate." From what cause evaporation ensued others must determine. With ourselves the pair of remaining green plovers became wondrously familiar, so much so that in the depth of winter they would come and stretch themselves on the kitchen hearth, first obstinately driving both dogs and cats from thence, as we always checked resistance on their part. In general the lapwings passed us without any recognition whatever, and it was only when warmth was desirable and the cats seemed disinclined to be aroused whilst enjoying their customary nap that any interference of our servants was required.

But to revert to summer time. None but a close observer of the habits of these birds could imagine the amount of insectile food they consume, nor would accredit the careful manner in which they quarter every nook and cranny within their range. On grass plots they are at once most beautiful and advantageous; it is there, perhaps, they appear to greatest advantage, though, I believe, their utility is even still greater on the ground subjected to spade culture. Plovers will, particularly at eventide, stand perfectly motionless, awaiting the first glimpse of any loabworm, as it appears partially exposed on the surface. They then, with a few hurried and stealthy paces, approach within reach, seize it greedily, and rarely fail to drag it out at the first effort; but occasionally I have seen them first pull very carefully to prevent the worm breaking in pieces by the unusual strain, and then put the foot on the part extracted to permit the opportunity of taking a second and firmer hold with the bill, so that eventually the worm has been withdrawn entire. To any of your readers conversant with the tenacity of hold exercised by the dew-worm, if an attempt is made to withdraw it with the fingers, the force requisite on the part of a bird so small as a plover to remove it thus forcibly may be easily imagined. But I have seen the bodily strength of our favourites so severely tested that after pulling for a minute or more only a half of their prey was secured. The "peewit," as the plover is frequently called, is not only one of the most graceful and brilliant-plumaged, but also one of the most extraordinary birds in its gait of any of our British birds. Their quick motions and the elegant appendage of crest render them novel to the eye, and every motion of the bird is strongly portrayed. They must be supplied with shallow water to wash themselves—a habit they daily indulge in. We reared others with equal kindness, and they became equally familiar, though they were mostly impatient of strangers; but even this peculiarity was an advantage when understood, as, by their repeated cries, they never failed to draw attention when encroached upon, however protracted the interference, during night or daytime, though becoming at once silent and satisfied when either myself or sister spoke to them.

Although one particular pair remained with us more than half a dozen years, these birds never evinced any propensity to nesting; for it is certain they never laid at all, or their eggs would have been met with.

From the lightness of the plovers themselves, and the slight construction of their feet, they never did damage by overrunning the growing crops; and I confidently believe that any one taking the trouble to raise a pair for his own purposes will agree with me it is not a trouble thrown away; nor would I have extended my remarks to the particulars I have done had I not wished that every attempt to rear them that may ensue from reading our method of management may insure success to the less

experienced. I will merely repeat the present is about the time of year when young plovers are procurable.—EDWARD HEWITT, *Sparkbrook, Birmingham.*

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE weather is now favourable for carrying on the various operations of planting and sowing. Where any main crops in the kitchen garden have failed more seed should be immediately sown; where they have partially failed, procure plants, if possible, to fill up. Now is the time to destroy slugs late at night and early in the morning; they have their hiding-places, and may be destroyed by thousands with quicklime, which should be strewn over every part of the garden several nights or mornings running. It should be done in the morning by three or four o'clock, and at night not before nine. By persevering a short time a garden may be entirely cleared of this pest. *Beet*, thin the plants to a foot apart while they are small; fill up vacancies with those drawn out, they will produce plants equally good with the others. If the first crop has altogether failed it is not yet too late to sow another. *Broccoli*, make another sowing of both early and late sorts, the former to come in in October and November, and the latter late in the spring. *Cabbage*, earth-up those that were planted early in the spring; tie-up the leaves of a few of the most forward of the autumn-planted, to cause them to form hearts for early use. *Celery*, continue to prick-out seedling plants. In planting-out a second time, before finally transplanting into trenches, make a bed of equal parts of rotten dung and loam, about 4 inches thick, on a piece of hard ground, so that at the time of planting the whole of the earth and dung may adhere to the roots after the trowel is passed between each of the plants. A few trenches should now be got ready for the earliest *Celery*. On soils with a wet bottom the trenches should not be made too deep, so that the plants may be nearly on a level with the surface of the ground; a dry bottom with deeper soil may have deeper trenches: in either case, give the rows a good width because the *Celery* should never be earthed-up until it has nearly attained a size fit for use, and, therefore, the intervening spaces may be cropped with Lettuces, Early Dwarf Cabbages, and Cauliflowers, all of which would come off before the final earthing. *Cucumbers*, the ridge recommended last week will now be in a proper state to receive the plants, let them be got in without delay, and shade the glasses for a few days. At the same time a few glasses may be sown with seeds of Vegetable Marrows and Cucumbers for succession and for Gherkins; for the latter purpose on warm soils seeds sown in the open border will suffice; but on colder soils it is better to forward them in pots, and have a sloping bank thrown up facing the south; plant them near the top, and train the vines downwards, stopping them occasionally. *Dwarf Kidney Beans*, plant-out those that were sown in pots or boxes in rows 2 feet apart on a warm border. Another sowing should also be made. *Leeks*, make a sowing, to plant-out for winter use. *Peas*, stop the early crops as soon as the first blossoms are well set. *Parsnips*, they require to be thinned to 9 inches or more apart if the ground is rich. *Tomatoes*, plant them out in light compost under a south wall, also Chilies, Capsicums, and Basils, in doing which, if they are at all pot-bound, let the roots be gently loosened and spread out.

FLOWER GARDEN.

Push forward late propagated stock, and endeavour to keep the whole healthy and growing slowly in the pots. It is a common but erroneous practice to allow bedding stock to remain in very small pots, exposed to the sun and wind and very scantily supplied with water until it is almost dried up, and such plants are considered to be hardened-off. They should be exposed to the weather as freely as circumstances will admit, but never to such an extent as to brown the foliage and dry-up the tissues. Now is the time to establish a firm and even sward or lawn. The roller and scythe will be in frequent request, and much labour is involved in these operations properly carried out. See that the edgings hitherto neglected are put in order for the summer; do not edge beyond the original boundary, and keep the walks filled with gravel. Let the roller be passed frequently along the edges in order to level them down to the walk, this takes away the harshness of the outline.

FRUIT GARDEN.

During the process of nailing-in the shoots of Peaches, Nectarines, and Apricots examine if there are any nails so placed as to

be likely to injure the swelling fruit, and remove them. Use strong cloth shreds cut to a sufficient length to allow plenty of room for the wood to swell; such short shreds are sometimes used and bound close round the wood, so that at the winter pruning many of the shoots will be found to have an indented ring, and very often a large piece of gum. Vines will now require constant attention in stopping and nailing-in. See that the red spider does not get a-head on wall trees, nor the caterpillar on Gooseberry bushes.

STOVE.

All here is growth, treat them, therefore, liberally both at root and branch. Keep a brisk growing temperature, with plenty of air. Take care to pot such things as require it in time. *Stephanotis*, *Gloriosa*, *Allamanda*, *Dipladenia*, and other climbers will now be showing bloom; keep the branches from becoming entangled, but there should be no hurry to train them until the flower-buds are of a good size.

GREENHOUSE AND CONSERVATORY.

Look well after young stock, especially that for the ensuing winter's work. The early-sown Chinese Primroses and *Cinerarias* should receive frequent and careful attention, these will bloom in October and November. Another sowing may be made shortly for spring decoration. Continue successions of *Achimenes*, &c., from the rest stock. The *Chrysanthemum* cuttings may be put out immediately; these will do without bottom heat. Choose the short-jointed wood, they will strike freely under a hand-light, to be shaded from the sun. *Achimenes* to be placed in either of these structures when more air can be given; stake out neatly as the shoots advance. *Gloxinias*, like the above, require a partially-shaded situation and moist heat. *Gesneras* may be treated in the same way, with the addition of more light. *Amaryllis*, &c., to be removed to the conservatory for blooming, where they are a great acquisition. Although a slight shade is necessary on the forenoons of bright days, this must be used sparingly when the weather is unsettled; for without abundance of light flowers never colour properly, and they soon fade if kept in too shady a position. Where it can be conveniently accomplished watering should be done in the morning, in order to dry up the superfluous moisture before evening so as to avoid night-damps. The New Holland twiners, when done flowering, to have their shoots well trimmed-in before growth commences.

W. KEANE.

DOINGS OF THE LAST WEEK.

It is rather tantalising to hear from different parts of the country of the fine rains that came just when they were wanted. Now, on this, the 7th of May, we have yet had no rain, though several times we were sure it was falling some miles away. In these circumstances, as we depend almost entirely on rain water, we have had to be very careful in watering, and could not give some things anything like the quantity they ought to have had. Many crops we have even partially shaded to prevent the ground getting too dry; and among many of them we stirred the surface to keep it loose, and from cracking, and thus prevented the heat entering, which would have been acceptable enough but for the dryness from evaporation that would have accompanied it. With this dryness there have been several rather sharp frosts, which did little damage, as the air was so still and dry. Having seen no bad effects, we began to be rather too secure, and were partially caught on the morning of this day week, the frost having blackened the Potatoes, and injured very heavy crops of Gooseberries, and they would have been more injured still but for the thickness of the foliage. All the fruit that were at all exposed were blistered at least on one side. A little rough hay shaken along the rows of the Potatoes, and very gently on the tops of the bushes, would have saved them nicely, and also the blooms of some early Strawberry plants on a south border. For want of it every open flower was dyed black in the centre where the fruit should come. A few *Calceolarias* covered with thin calico were also a little injured where the cloth touched them, whilst those a few inches beneath it were safe, and also some standing exposed in sheltered places. Walnuts, &c., in the neighbourhood were much injured, and, as it may be interesting to some to know, in these and other cases where trees were affected the lower branches were most injured, whilst the loftier and more perpendicular branches escaped. The why may afford occasion for thought and investigation.

Emptied a frame over a shallow hotbed that had been filled with cuttings, turned the manure over, placing fresher at the bottom, and raising the bed at the sides and ends for the frame to stand upon, leaving the space open in the centre for soil, so that the soil should be below the level of the bottom of the frame, and as the soil was soon warm enough, planted-out strong plants of Cucumbers. Our frames are generally about 18 inches at back, and 10 inches in front. When deeper they are lumbering to move about, and the advantage of a frame over a pit is, that it may be easily moved where most needed. This depth is not enough for Cucumbers, if the frame is set over the bed in the usual way; but by making a wall or ridge of sweet manure some 16 to 18 inches higher than the centre of the bed, there is plenty of space left for soil and foliage, and the bed being so much shallower in the centre than at the sides, there is little chance of the roots being burned or overheated.

Put about 15 inches of rough littery material having a little heat in a shed for a Mushroom-bed; beat and trod it firm, and covered with a couple of inches of good horse-droppings. This, after five days, has emitted a nice gentle heat of about 80°, so spawned it over in the usual way, placing pieces of the size of walnuts every 9 inches over the bed, and with the upper side just covered with manure or scarcely so. Placed an inch of horse-droppings over all, and beat firm again, and will leave the bed without earthing to see how the heat goes; as, if still very mild, we will give an inch more of droppings before earthing-up. The side of the shed being open to the west, broke the current of air there with bundles of pea-stakes. Straw-thatched hurdles may be used in the hottest time of the summer. The reason for making such a shallow bed is that we do not want to wait long for Mushrooms; and if the bed had been thicker or of better materials we must have waited longer before we could spawn and earth-up with safety. The reasons why we wish to hurry on this bed are twofold—first, because we wish the old beds in the Mushroom-house to be had for manure for flower-beds, &c.; and secondly, because we are a little doubtful of the last, and a promising bed in the Mushroom-house will do a very great deal more of good as to crops of Mushrooms.

Our good assistant in the Mushroom-house was bothered with woodlice, which he could not trap fast enough, and resolved to daub and catch them with tar. He poured it down at back and front of the bed, and there numbers of these gentry were held fast by something more impassable than birdlime. As soon as we smelt the tar we knew too well that the Mushrooms in view would die or be uneatable; and we are doubtful if those coming like pinheads will do much good, as the fumes of the tar still remain, though it was removed as carefully as possible. We might not have adverted to this fact of the tar, but for two complaints. One gentleman says that in a lean-to pit with a very white back wall he found his Cucumbers were blotted and burned, notwithstanding the air carefully given; and seeing that we recommended darkening the wall so simply as with soot paint, he thought he would improve upon it by painting the wall with tar and oil, and lo and behold! the morning afterwards, there was not a single healthy Cucumber-leaf in the house. Another gentleman has ruined a house of Melons from the same cause, and tells us he ought to have been guarded against such a fatal mistake, or why does he pay for *THE JOURNAL OF HORTICULTURE*? Well, we are very sorry for both mishaps, though we hardly think our serial is much to blame, as, again and again, the admonition has been given to be careful of using tar inside of a plant-house, and that if used at all the tar should be applied six months or more before the house was used. We prefer to act on the safe side, and never use it on the inside at all, as, if much heat is used, the fumes will be given off months after it seems to be thoroughly dry; for outside work and dried before plants are brought near it, there would be no danger. If a place were tarred inside in summer, and no plants put in until winter, they might be safe then, especially if air were left on night and day.

Watered Cauliflowers, Peas, Turnip Radishes, and Lettuces. Sowed successions, damping the soil in the drills, and shading. Pricked-out Lettuce, Basil, Savory, Chilies, Capsicums, &c. Potted Tomatoes, and staked Peas, and sowed Kidney Beans and White and Scarlet Runners.

As an evidence that our Irish compatriots receive, at least in some places, their fair share of the gifts of Providence, we may mention that a valued correspondent informs us that at a show at Wexford the other day there were good young Potatoes fit for use from the open garden; and that at the same place Peas and Broad Beans were in bloom and pod.

FRUIT GARDEN.

Regulated foreright shoots, nipped and disbudded Peach-shoots, and tied, hunted for insects, watered cherry trees, especially setting their bloom, as a few pots of water then often make much difference. We have noted how forward blooms of Strawberries were injured by the frost of the last day of the preceding month. Run the hoe through Strawberry-quarters to keep the moisture in and to prevent the ground cracking. This will enable the rain to penetrate more easily too when it comes, and a good soaking before long would just make all sure for a heavy Strawberry crop. Turned out pots of Strawberries from the houses as soon as the fruit was gathered. The crowding now is not good for the permanent crops cultivated. We will put in the later houses one more batch of plants that are now in blossom, and if there should threaten to be a hitch, we must then forward some out of doors with lights placed over them.

We have scarcely been beyond the garden walls for a long time, but we saw two long shelves of Strawberries in a span-roof house at Luton Hoo yesterday, which we think worth noting, not only for the excellence of the crops, chiefly British Queen, but more especially as the method adopted is not only very simple, but one that we have already several times recommended. The shelf cannot be simpler. A common board, perhaps, about 7 or 8 inches wide, and on this is placed a turf of about 1 inch thick, and the same width as the shelf, the grassy side being turned downwards. On this turf the pots are placed, and the roots were running into it, and one advantage is, that it is scarcely possible with common treatment to over-water the plants, and another advantage is, that the turf becomes a reservoir alike of nourishment and of moisture, whilst the latter can never be presented in such a shape as to make a morass plant of the Strawberry. There was another striking feature. As the doors were standing open the shelves on each side seemed to be adorned with drooping verdure, which gives a cool very refreshing appearance to the fruit, owing to the grass from the turf being allowed to grow on each side. Some might have preferred cutting it off, but in the situation referred to we think the grass added an attraction to the scene. Some-day we shall give an account of these new houses, meanwhile we regret that we cannot give the exact position of these shelves, as that we think has something to do with the success; but we may state from memory, that the shelf was $2\frac{1}{2}$ feet from the apex of the house, and some 15 inches from the sloping glass of the roof. We may also mention for the purpose of directing attention to the point, that in another house with sloped roof and hipped at back, a shelf was also looking well, but was evidently too near the glass when compared with the preceding one. The pots being so near the glass must have been excessively hot in very sunny days, and to neutralise the effect of that a very thin slip of wood, and nearly as deep as the pots, was slipped in between them and the sloping glass, and thus the south side of the pot would be little hotter than the north side. This shelf was too near the glass to permit of the turf being used, but Mr. Fraser proposed lowering it next season so that the plants should be further from the glass. We find that when the plants are close to the glass, though good fruits are obtained, the flower-stalks are much more stubby, and, of course, they are more liable to feel the effects of sudden changes of temperature and atmospheric moisture.

We feel much interested in the account "FRUIT-EATER" gives of his failure with Keens' Seedlings. The tiniest little plants will generally show bloom the first year. The failure of "FRUIT-EATER" is so much like the case of a merchant which we described a year or two ago, that we do not thoroughly coincide in our good Editors' idea of the barrenness not being owing to extra luxuriance. We think that over-luxuriance, too much manure, and too much rich manure-waterings in autumn, will keep on growth instead of inducing the forming of fruit-buds. Our merchant friend, a little earlier than this, was much astonished on beholding our black looks on taking us to see what people said was the most splendid bed in the neighbourhood; and so it was, if he had been content with leaves instead of fruit. We saw there would be few blooms; and we think, instead of several bushels he did not get above five or six ounces of fruit. As far as we could make out the plants were planted in the end of July. The ground was heavily manured; the plants were thoroughly watered up to the end of October with soap-suds, drainings from the dung-hill, &c., and the result as above. Part of the plants were destroyed, and others planted in the same place, which did well. Part were left, and these were kept thin in summer. Not only the runners, but even the buds were thinned; and as they stood

their ground well without the waterpail, no waterings in summer or autumn were given, and the following year there was no end of fruit-buds and flower-trusses. As a general rule, though Strawberries delight in rich feeding, they like extra supplies best in spring as the fruit is coming on, and in summer when exposed to a powerful sun; rich feeding and manure-watering in autumn, as in the above case of our merchant, are apt to do more harm than good. Perhaps a "FRUIT-EATER" may from this case gain a hint, as it is the only one we know of that so closely resembles his own. We suspect that this is also the opinion of the Editors.

One little fact more about Strawberries, which is no less a fact, though we are not learned enough to give a clear-enough outline even to please ourselves how it is so. The fact is, that Strawberries when forced moderately early, and planted-out in the open ground, will give you some nice fruit in the autumn, and an extraordinary crop the following year—such a crop as would be looked for in vain from any young plants, or even those rising two years old, if both received the same common treatment. We recollect hearing this matter talked over some twelve years ago at a festive party, which some of us will never forget, though several of the brightest spirits there have gone home since then. Among others, C. W. Johnson, Esq., well acquainted with gardening, but more distinguished as an agricultural chemist, could understand very well how a crop of a certain kind could be obtained in autumn, and could not see on what principle, after the exhaustion of two crops in one season, the plant should have such fruitful energies the following season. Well, there is a nut to crack. Many can confirm the fact from their own experience, and many can also say that these also come rather earlier than other plants, the last season's runners coming next. When we have repotted such plants, we have also had heavy crops, but we never followed that plan up much; as, though the fruit was so plentiful individually in pots, the specimens were not so fine as those obtained from young plants, though, no doubt, much might have been done by thinning freely, if time had permitted.

One fact more as to these forced plants when turned out. This fine crop the first season afterwards is all that can be urged in their favour. When ground is limited they ought not to stand after that first year. Every season they remain afterwards there will be declension and decline in quantity and quality.

ORNAMENTAL DEPARTMENT.

Much the same as last week, potting, protecting, pricking-out, stering, and shading, &c.—R. F.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c."* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

INSECTS ON MELONS (*E. Hurst*).—The insects sent are several species of small rove beetles (*Staphylinidae*), which are generally considered as feeding on other insects or on decaying vegetable matter.—W.

POLYANTHUS SPORT (*C. Daniel*).—The calyx has become leafy, and the sport probably will not be permanent.

MOWING MACHINE (*John Eolland*).—We cannot recommend one maker in preference to another; you must read the advertisements in our Journal, and select that which promises to suit you best. If kept in good order, any one of them will do what you require; but to be worked by one man we would have it narrower than you mention.

TENANT REMOVING GARDEN BUILDINGS (*Ohio*).—All buildings may be so erected as to be removable by a tenant at the end of his term; but we cannot afford space to enter into details. If the foundation is of brick, have a plate of wood fixed to it and to that plate have the superstructure attached by screws. The whole superstructure may be then removed. The boiler, pipes, &c., may be removed also.

WORK ON THE VINE (*J. M. McClellan*).—Sanders on the Vine would suit you probably. You can have it free by post from our office if you send your direction with 5s. 2d., either by a post-office order or in penny postage stamps.

TALL TREES FOR A BLIND (S. E.).—You will find it no easy task to move trees 50 feet high with the care requisite to insure their success even in autumn. You live so near to London that you had better visit some of the large nursery grounds and select for yourself. We have found, even on a chalk soil, that the White Poplar established itself the most readily, and formed a blind in summer the most speedily. We have answered another correspondent about lawn mowers.

FLOWER-GARDEN PLAN (K.).—We like your flower-garden arrangement. The mixtures will do for the borders if they please you, but we have no doubt that the plants would look best by themselves—that is, Koniga, Flower of the Day, and Manglesii, instead of mixed any way with each other. We once saw a variegated border chiefly of Geraniums, but it was a poor affair. We thought the plants wasted.

VARIOUS (Q. Q.).—*Colens Verschaffeltii* may be nipped to keep it dwarf, indoors or out of doors. We think that out of doors it will only do well in warm, sheltered places. *Gazania splendens* rather prefers stuffy loam; but we have seen it thrive in all manner of soils. We presume your beds were too good and rich, and hence the extra luxuriance. We would leave the two shoots on the Vine at the spurs in the circumstances indicated—that is to say, if we wished the two bunches.

USE OF A COLD FRAME (W. M.).—The best advice we can give you is to buy and read "Window-Gardening for the Many," and if you go no farther back, read "Doings of the Last Week" since January. Meanwhile, for your encouragement, we would say that you can do all you propose with your frame 20 inches at back and 14 inches in front, and consisting of three lights, but not merely "by putting stable-litter inside of it and shutting it up close," for that would most likely kill all your cuttings, and seeds too, as soon as they were above ground, even without putting in renewals of fresh litter. The first thing you must do is to have your litter made sweet—that is, all the dangerous gases that smell somewhat like hartshorn must be driven off; or, if you use the dung a little fresh, you must cover with old dung, or earth, or ashes, to a sufficient depth to prevent these gases coming through. Now, for such a case as yours, we would throw some dozen or a score of good barrowloads of litter together, watering it where dry. In a week or ten days turn it over, placing the top to the bottom and the sides to the centre. In another week it will be partly wrought or sweetened, but not enough to put plants among it. For that, most likely, it would require other eight days; but, to save time and litter too, we will make the bed with it as it is—larger than the frame by 1 foot each way, which will leave 6 inches at ends, back, and front. Place on this 4 inches of rotten dung or leaves, or 3 inches of earth, and beat or tread well, and then 3 or 4 inches of cinder ashes. After you set the frame on the bed, presuming that the dung is of a depth of from 15 to 18 or 20 inches, the heat will last a good while after the middle of March, and you can plunge your plants in the ashes; but even then, to make sure, leave a little air, though not more than a quarter of an inch, at the top at night. When the heat declines, and you wish for more, move the ashes and the rotten dung. Turn the bed over, putting the fresh at the bottom and replacing the rotten dung or ashes, &c., on the top. If neatness be your object, you might sink a hole for the dung, and the frame would look as if it stood on the surface. All seeds, seedlings, and all potted plants such as you allude to—and, in fact, all plants except those needing more heat—will be benefited by being plunged in such a mild hotbed, because an impetus will be given to root-action; but one thing you must look after, and that is that the encouragement may not be so great as to lead the roots through the hole at the bottom of the pot and into the bed; and then, if the roots have travelled far, the plants will receive a check when you move them. To prevent this, after ten days or so you should lift the plants up, and do so frequently to prevent them rooting beyond the pot. In fact, when they begin to do so, you could remove the pots where they had no hotbed beneath them. Then to the question, "if seeds and cuttings should have air and light, or either, or neither," we must just say that seeds need no light until the seedlings appear, and they will most likely get air if the seeds were not buried, and in that case there would be no seedlings. After the seedlings come they must have air and light too, or they would undergo the fate of our countrymen in the blackhole of Calcutta; but, as they are tender, the air must be given judiciously, as you would give it to a young infant, and the light must be proportioned to their breathing power, as a powerful midday sun might shrivel them up, especially when under glass, and therefore a little shade would be useful in the brightest part of the day. Then, again, if you take off a cutting with leaves, the more air and light the cutting will stand the more robust it will be and the sooner it will strike; but if air and light are given in such quantities as to make the leaves flag and wither, you will either delay the rooting of the cutting or kill it altogether. Unless we could write a Number to suit your case, we must refer you as above for details, and, perhaps, more especially to the little book, which you can receive from this office by post for ten penny stamps.

MELONS SCORCHED (A Constant Reader).—If the roots are burned much you will do more good with young plants. If only a little, water well after you have put fresh soil on the surface. We have not much faith in the plants doing well if much injured. Remove the soil from the surface of the Fern plant as deep as you can well do. Better repot in fresh at once. If you do not like that place some lime on the surface, but remove before you water much.

DESIRABLE KNOWLEDGE (D. B., a Young Gardener).—Your letter is very creditable, and we will think it over. It is honourable to wish to know what most deserves study. In the meantime we would say in all kindliness, do not plume yourself on your Latin, or any other extra knowledge, but get thoroughly indoctrinated into the minutiae of gardening, and read the article by Mr. Fish bearing on the subject some time ago.

KALMIA NOT FLOWERING (A Subscriber).—If the Kalmia is kept moist enough in summer, and has plenty of light, there is almost certainty that it will form flower-buds.

HOYA CULTURE (Idem).—The Hoyas require a very open compost, and plenty of light. We suspect the buds of Paxtoni fall off from too much moisture, or deficiency of drainage. Peat, a little loam, and broken bricks and lime rubbish grow them well. Hoya imperialis requires much the same treatment, and plenty of light, and an average temperature of from 65° to 75°. *Rhododendron javanicum* will do very well in a cool greenhouse or cold pit. Such things as a shoot dying will take place, and the best doctors will do nothing but talk as to the reasons. Ainery will be too hot and shaded.

BOUGAINVILLEA SPECIOSA (A Subscriber since 1856).—We can only inform you that this most beautiful creeping plant is a native of Brazil, and appears to have been first portrayed under that name by Schnitzlein, in his work entitled "Icones Familiarum Naturalium." The first record of its flowering in this country is that it did so in 1853, at Alton Towers, under the care of Mr. Whitaker, then head gardener there. It has since been bloomed elsewhere, and the requisites seem dryness and high temperature to the roots, and training it close to the glass also in a hot, dry atmosphere.

PAXTON HOTHOUSES—SIRKIM RHODODENDRONS (An Irish Subscriber).—We believe those who have tried such houses for common purposes have found the ventilation sufficient, when air was given early. We think that for some things the air would hardly be enough, unless the doors or the triangular space above them were also opened; but it is easy to obtain any amount of air by setting the sashes farther apart. We think the chief recommendation of the plan is the ease with which the whole can be put up and taken down and sent from Land's End to John o' Groats. We are glad the Rhododendrons do so well with you in the north-west of Ireland; they seem quite at home in Ireland. The best time to graft them is just before the shoot-season begins to move. The keeping rather close afterwards will soon cause the union to be effected.

ERROR.—In my article of May 5th, page 326, you print, "Simply because, if carried to any distance, the pressure on the bottom of the boiler and flow-pipe is so great, &c." This should be "return-pipe."—J. E. L., JUN.

NAMES OF PLANTS (F. C.).—*Asphodelus luteus*; *Spiraea laevigata*. (Northumbrian)—*Oncidium pulvinatum*. (M. D.).—1, *Cheiranthus ochroleucus*; 2, *Saxifraga hirta*. (J. F.).—1, *Nothochlœna chrysophylla*; 2, *Erica pubescens*; 3, *Fleurandra* (apparently) *ericaefolia*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

BATH AND WEST OF ENGLAND POULTRY SHOW.

I AM much pleased with your excellent remarks in last week's JOURNAL OF HORTICULTURE, respecting the contemplated arrangements for the Bath and West of England Poultry Show. I quite concur with the statement as to the high popularity it has for many years enjoyed in the poultry world, and very deeply regret that the rules which have hitherto guided this Society should be so changed, or at least so complicated, as to place a real stumblingblock in the way of its future well-doing. That all specimens of poultry and pigeons committed to the care of the managers in years past have received the greatest care and attention I feel certain no one will deny; but the complaint has always been raised of the needlessly protracted time the birds are confined prior to the adjudications. True it is that the rules, when first issued, fixed Friday June the 5th as the latest period of receiving poultry, and to meet the above general objection, an extension of time to the evening of the day following is consequently allowed: yet this by no means meets the requirements of those exhibitors who, possessing the best of specimens, feel a natural reluctance to hazard the possibility of a delay during their transit that might either place them beyond acceptance in the showyard at all, or cause them, if returned, to remain neglected at some roadside station, and compel them to be forwarded to their respective owners without any refreshment whatever, solely on account of the next day being the Sabbath.

This feature will compel many other breeders as well as myself from feeling as strong an inclination to support the Bath and West of England Society as we have previously done, although the prize list is remarkably liberal. It is in contradistinction to your remarks in last week's paper, officially stated, the fowls will not be judged until Monday morning, and that then "open judging" in the actual presence of all parties, whether interested or otherwise, will be practised. On the worse than impolicy of "open judging" I will not add one word to your observations; but I earnestly protest against the probable difficulty of poultry being so miscarried as to be forced to remain without any care or attention, if by any neglect of the railway the fowls do not arrive at Exeter at the appointed time, and that for a period so long as to inevitably insure them permanent injury. If they were judged on the Saturday all this might be obviated.—COCHIN.

CROOK'S PATENT PHEASANT FEEDING-TROUGH.

THERE is no doubt that this is a very ingenious contrivance, if pheasants will resort to it—they open it by merely perching on a handle, which they would be tempted to do by seeing the food through a small glazed aperture in the lid. We feared that the noise attendant upon the lid opening, and the lid touching the bird's breast in opening would drive the birds away, and

we wrote to Messrs. Crook expressing our fear. Their reply, from which the following is extracted, is satisfactory:—

"We are exceedingly obliged by your communication, and beg to state that a feeding-box of a similar construction has been in use some years, the cover opened in front like ours. We fix glass on the cover that birds may see the food, which we think useful in teaching young birds to find their food. The main objection to the old make was that in consequence of the action passing inside the food-chamber it became clogged, would not work, and remained open, and other animals devoured the contents. Some gentlemen from the north came last week to inspect them, one of them left an order for twelve; another one sent an order this morning for twelve, and says he will send a lot of old ones to alter like ours."

CAUTION TO ADVERTISERS.

PERMIT me to caution the advertisers in the Journal against supplying goods of any description to applicants from Manchester, without the cash or a respectable London reference.

The Long firm has just favoured me with a good order, to be left at the London Road Station till called for. In this instance, however, the swindlers have only lost their time and postage stamps.

Nothing comes amiss to these scoundrels. No sooner does a new advertisement appear than an order is given, which in too many instances is successful in obtaining goods, the promised post-office order being never remitted.

Application to the police is in vain, as the matter is merely one of debt; and legal proceedings are equally useless, as the fellows shift from one hiding-place to another with the greatest rapidity.—AN ADVERTISER.

CLIMBING BIRDS.

THE tree-climbing or creeping birds are of various species, as the Creeper, the Nuthatch, the Wryneck, and the Woodpeckers.

THE CREEPER or Tree-crawler, is a small dark brown bird that visits this country only in summer. The bill is long and slightly curved; the claws sharp and well adapted for clinging to the trunks of trees, which they do in search of insects, of which their food consists. They form their nest usually in a hollow or hole in a tree.

THE NUTHATCH remains with us through the winter, hunger making him bolder, when he is more frequently seen, and may be occasionally caught and tamed. The male is a rather handsome bird, with his bluish cloak and orange vest, a blue mark on the forehead, and a black streak from the beak across the eye. The female is not so brightly coloured. They build in holes in trees and feed on insects, which they collect by climbing the stems and branches of trees, and in this they are very expert, surpassing Blondin or Olmar in their gymnastics.

THE WRYNECK, Snake Bird, or Cuckoo's Mate, is a delicate summer visitant, arriving in England about the same time that the Cuckoo does. They build in hollows or holes in trees, and have a peculiar manner of writhing or twisting the head and neck. The bill is straight, rather long, and the tongue is very long, by which they are enabled to catch the insects on which they feed. The feet are formed like a parrot's—two toes in front and two behind, so that they can climb easily. The colour is greyish, streaked and barred with darker shades.

OF WOODPECKERS we have three or four kinds natives of England. They are known in different districts by various names, as Woodwale, Yaffler, Gally Bird, &c.

The Great Spotted, the Striated or Lesser Spotted Woodpecker, and the Green are those generally found in this country. They have strong beaks, with which they rap the limbs of the trees to frighten the insects; they thus cause a jarring or vibration, which makes the insects run out and expose themselves, so that they can feed on them. Their tongues are peculiar in form and they can dart them out to some distance, and thus secure their prey. Their feet are formed with two toes turned back and two in front. The tail is short and furnished with stiff points to the feathers, which assist the bird in climbing. They are all very useful birds, destroying and keeping in check those insects that work beneath the bark of trees and thus injure much valuable timber. In forming a hole for their nest they only bore into a decayed part, not into sound wood as some suppose, which would be far too hard for their tools. As they do no injury of

any sort, but are very useful in preserving timber trees from the undue attacks of insects, they, as well as the other tree-climbing birds, should be protected by all growers of wood or trees; and it is hardly to be doubted that those trees, of which we so frequently hear complaints of their dying from insects burrowing beneath the bark, would have been saved if the Woodpeckers and other tree-climbing birds had had access to them.

I have now concluded my articles on small British birds, and it only remains for me to offer a few remarks on the larger birds as Doves, Game, Waders, and water birds in my next.

It may be thought that I have omitted the hard-billed or seed-birds—such as the Grosbeaks, Finches, and Buntings; but I have so recently described them in my series on "The Canary and British Finches" lately published in this Journal, that it is unnecessary to recapitulate; and I have nothing to retract and very little to add, except to thank "ORNITHOLOGIST" for his fact in support of my assertion that more fruit is set on those trees and bushes which are disbudded by the Bullfinches. I only regret that he did not append his real name to his communication, as a *nom de plume* rarely carries so much weight in authenticating a fact as the signing of a correct name.—B. P. BRENT.

BEEES TRANSFERRING THEIR ALLEGIANCE.

A CIRCUMSTANCE took place in my apiary a few weeks ago which I deem worth relating, as illustrating Mr. Lowe's remarks in page 61 on the partial deserting of hives.

On the 2nd of last month I placed in my garden a strong hive of common bees which had come from a distance, and the bees had therefore passed some days in confinement. They rushed out as soon as liberated, standing in a crowd round the entrance, and with vibrating wings, sang loud peans in triumph over their recovered liberty. Numbers took wing, and each as it returned added its quota to the universal jubilation. Having occasion to examine the next stock (a pure Ligurian one), I thoughtlessly and unfortunately opened its hive whilst the excitement was at its height, and the consequence was, that nearly every worker deserted it and joined the noisy ones, leaving the poor queen almost "alone in her glory." Here was a dilemma! and what was now to be done? Ligurian colonies are by no means to be trifled with, and this one having a young, remarkably handsome, and pure queen, was destined for the apiary of "A RENFREWSHIRE BEE-KEEPER." Whilst I deliberated in perplexity, the poor queen, evidently disgusted at the turn affairs had taken, presented herself at the entrance, rubbed her eyes in astonishment, and attempting flight fell at once to the ground. This brought matters to a climax, and as soon as I had secured her (which was not immediately, for she fell amongst some grass, and I had to hunt for her), I popped her into a queen-cage with two or three of her remaining subjects, and put her into her hive. So far so good; but what was to be the next move? To tell the truth matters looked rather unpromising. I thought at first some of the truants might return, or that at any rate those that had gone honey-gathering would come back to their old home and comfort their sovereign in her distress. Not a bit of it. Louder and yet louder pealed the song of triumph next door, swelled now by the recreant voices of the traitor Ligurians; and if by chance a stray pollen-laden bee looked into its old habitation, it was only to depart immediately, evidently impressed with the conviction that it did not lodge there, and that it was bound at once to accept the hospitable invitation which resounded unceasingly from the portals of the adjoining mansion. Once more I looked into the deserted hive, and took stock of its contents. Food there was in abundance, and good brood-combs; but for inhabitants, only the forlorn queen and her three attendants traversing unceasingly their narrow prison.

Desperate diseases require desperate remedies; and although I knew the danger of introducing strange bees under such circumstances, I had no other course to adopt. Brushing off the noisy cluster that had occasioned so much mischief, and disturbing the hive as much as possible till I was surrounded by a cloud of combatants that speedily exchanged their notes of joy for a cry of vengeance, I bore the offending colony to the other side of the garden, and substituted for it the abandoned hive. It was amusing to observe the instantaneous change that took place. All appeared unwilling to enter the deserted mansion; but roamed disconsolate outside, ever and anon taking wing and returning once

again after circling round and round in the air in the vain attempt to discover their lost treasures. Ultimately they entered the hive and clustered over the brood-combs; but still the doorway presented a scene of confusion, whilst within a dense knot of would-be regicides clung to the queen-cage with bull-dog-like tenacity, striving by every means in their power to wreak fell vengeance on its unoffending tenant. During two days did this regicidal mania rage with unabated virulence; but on the third day it had so much subsided that I ventured on the release of the royal prisoner. Even then it was too soon, for though well received at first she was soon afterwards imprisoned by the hostile bees. Having effected her release, I was compelled once more to ensconce her in the queen-cage, whence twenty-four hours afterwards (four days from the commencement of her incarceration) I had the pleasure of liberating her and finding her well received by her heretofore-rebellious subjects.

The immediate effect of the mischance which I have above related, was to convert a pure Ligurian into apparently a perfectly black colony, since the Italians almost without exception stuck to their new colours; but I think the hive rather gained in population than otherwise. Before dispatching it to Renfrewshire, the Ligurian element had again asserted itself, whilst the queen laying eggs in abundance gave promise of that prosperity which I trust may await the hive in its new locality. —A DEVONSHIRE BEE-KEEPER.

THE BEST ASPECT FOR BEES.

In reply to Mr. Fox on the aspect for bees, I beg to state that from my experience in different places in the west of Scotland, I have always found hives facing from south-east to due north the best. At this moment I have hives standing in all directions, and those facing the north are a long way ahead of those facing the south, although the former were weak in autumn compared to the latter, and lighter in weight. They were later in commencing work in spring; but they are now sure to be the first at work and last to stop: hence their progress. As for the quarter that most rain comes I do not mind that. Wind is a greater enemy to them than rain, so that I always try to avoid the high winds. From south-west to north-west are the points that the higher winds come from in this quarter. Of course, I speak as if they stood in an open plain, and refer only to where I have had experience, and it teaches me to avoid the tempting rays of the sun in spring, and its burning heat in summer. As a proof, in 1861 and 1862, hives facing the north were the only ones that swarmed with me. —A LANARKSHIRE BEE-KEEPER.

QUEENS DESTROYED BY THEIR OWN WORKERS.

I OBTAINED a strong hive of bees in the autumn of 1861. In May, 1862, it threw off a strong swarm. Both stocks destroyed their drones in the first week of July. In February of this year both hives seemed in good condition, and on fine warm days were busy in collecting pollen from crocuses and the shrubby veronicas. One day I found a queen stupefied on the ground beneath the parent hive. On warming it in my hand it partly revived, and entered into the hive, but was expelled again and soon died. The bees, however, continued to work and carry in pollen, but after two or three weeks no increase in their numbers took place. About the end of March I observed a young queen come out and fly away. She returned in about ten minutes. On another fine day I observed this take place twice, the working bees taking no notice of her. The first week in April I found her one morning dead before the hive. The bees were not working, but running in and out in confusion even till late in the evening. This was continued the next day, and two or three hundred were scattered about dead. Since then the bees are quiet, decrease in numbers, and only work for a short time in the middle of the day, seldom before twelve o'clock, or after three. There is no confusion, they only appear lazy, and have no young ones. They carry in a little pollen. The other hive is doing well, as drones appeared on the first of May, and it is very strong. I presume I shall lose the hive, but shall be glad of an explanation, and whether anything could have been done. They did not want food. —J. R.

[The first queen which you discovered on the ground in a stupefied state, had, doubtless, been stung by her own workers.]

The second was a young one which they reared to supply her place, but as she could not become fertilised at that early season owing to the absence of drones she ultimately met the same fate as her mother. We have ourselves lost several valuable stocks this spring from the same cause, but we are utterly unable to assign a reason or prescribe a remedy for this suicidal conduct on the part of the bees. Although we have never seen it noticed in any English work on the subject, this phenomenon has not escaped the keen eyes of German observers. Dzierzon says that when a queen is found outside the "brood nest," she is always in danger of her life from the stings of the workers, and he accounts for these frequent regicides during an unfavourable spring on this hypothesis. We cannot say that we deem his theory in this respect altogether satisfactory; but we know of no better. The fact is, it is a recently-observed, mysterious, and very unsatisfactory chapter in the natural history of the honey bee, which it may be long ere we are able fully to unravel.]

LIGURIAN BEES DO SUCK THE RED CLOVER.

WITH regard to the query propounded in your columns as to whether the Ligurian bees suck the common red clover, on observation it will be found that this may be answered in the affirmative, at least in so far as my observations have gone. During last summer there were two fields adjoining my apiary: one of pasture containing a little white clover, and another of hay, containing white clover, red clover, and Alsike clover (*Trifolium hybridum*). This variety, which has been largely sown in Berwickshire of late years, has a close resemblance to red clover both in stalks and flowers, the petals, however, being all tipped with white, and probably not quite so deep as those of the red, but much longer than in the white clover.

During the wet ungenial weather which we had last summer, I noticed that whenever the bees could get abroad they invariably took to the hay field; and wishing to solve the question as to which of the three varieties they gave the preference to, on observation I perceived, contrary to my preconceived opinion, that they were working most anxiously on the Alsike and red clovers, leaving the white clover almost untouched.

However, it must not be inferred from this that the preference would be given to either red or Alsike in ordinary circumstances, as it is a well-known fact that in most seasons they decidedly prefer to luxuriate in the pasture fields of white clover when within reach in preference to the others; and we can account for their somewhat anomalous proceedings on the supposition of the white clover being opener and shorter in the flower-petals than the other varieties, consequently the nectarous juices were the more readily washed-out by the daily drenching rains which we had during the last summer, whilst the others retained part of theirs, and the Ligurians found it possible to extract these juices when favoured with a few hours of sunshine. —J. S.

DRONE-BREEDING QUEENS.

SUBSEQUENT to the date of my last communication on the "Mortality of Hives," wherein I expressed my belief in the practical worthlessness of drone-breeding queens, I find from a report of a meeting of German bee-keepers held at Potsdam, as inserted by Mr. Woodbury at page 270, that one of the subjects discussed at that meeting was this very question "Of what practical value is a drone-breeding queen in the spring?" and that an almost unanimous decision was apparently come to in the negative—namely that such a queen has for the "rational bee-keeper no value whatever." Now though this verdict of the German bee-keepers practically coincides with my own views on the subject, yet considering that these same apiarists are not always infallible in their opinions more than myself, I am much pleased to find that Mr. Woodbury is himself endeavouring to work out a solution of the problem by instituting, in the novel form he indicates in No. 109, a fresh inquiry into the subject. If he should be successful in establishing the affirmative of this proposition, "Are drone-breeding queens of any use to the apiarian in spring or not?" then he will at all events have the honour of upsetting the general belief among bee-keepers on the subject; and as the point is an interesting one, it is to be hoped that he will not fail to report the results of his present experiments.

Assuming the doctrine of parthenogenesis to be true, and viewing the subject in that light, there can of course be no

possible ground for doubting that males produced by drone-breeding queens in proper cells will be as physically perfect as those produced by normally conditioned queens in the ordinary way. Certainly it is not for me to express a doubt as to naturally reared and fully developed drones, by whatsoever queen produced, being physically perfect creatures and capable for all the uses which nature has designed them for. No: I have no such doubts; but it must be remembered that according to the strange theory of Dzierzon, in reference to which I made the comments on the subject, all drones, even the most perfect are "altogether imperfect creatures, for the production of which so many forces and conditions are not necessary, even on the part of nature as for the production of the queen, and, what is the same thing, for the workers."

Independently of the fact, however, to which I before adverted—that when drone-breeding queens are left to themselves, the males produced by them are generally reared in small cells, and that consequently we must consider such males as physically imperfect upon the same principle that we consider female bees imperfect because reared in small cells. Independently of this fact I am inclined to believe that there are other elements of an adverse nature which will unfavourably operate against Mr. Woodbury's experiment, notwithstanding all the helps and appliances which he has put into requisition in order that fully developed drones may be secured. Some necessary attending circumstances may be wanting—some essential conditions absent in all this artificial process which will militate against success, and prove the result not so satisfactory as anticipated. I doubt, therefore, if Mr. Woodbury will be repaid for the trouble he is put to, and the injuries caused to his other hives by the abstraction of brood-comb from them for the purpose of keeping up the daily diminishing population of his degenerate colonies; and that even should occasional experiments in that way be crowned with success, it would turn out that in practice failure would be more the rule than the exception.

As an experiment, however, of rather a novel character, I shall be delighted to hear of results which it is to be hoped Mr. Woodbury will not fail to make known in due course.—J. LOWE.

BEE-HOUSES.

WILL "A. K. H., *Westhorpe*," be kind enough to explain how he manages to exclude the wind and rain from his hives in his open bee-protector, while it allows the current of air to pass freely through? I have no doubt but his method is good; but judging from its appearance on the diagram at page 179, it appears to be a high, open, unsightly edifice in an apiary. But as he has not given a scale of the size one cannot say much about its merits or demerits.

Will he also explain how he manages to hasten the progress of the bees in spring by the heat of the sun? how he manages to keep the temperature the same at night in the hives by a few hours' sunshine through the day? From the experience I have had, the best heat I can get is to put my hives by in autumn well peopled, and from 35 lbs. to 50 lbs. gross weight, allowing 10 lbs. for hive and board, and well sheltered from sun and rain in the bee-houses, the construction of one of which I will try to explain.

It is a square-framed house 6 feet 6 inches long, by 3 feet 3 inches wide, and 5 feet 6 inches high over all, covered with five-eighth lining. Roof projecting and well ventilated, 1 foot 6 inches to the floor, where the hives stand—a height which I think is quite enough. The hives are all on one level, which is much better than having one hive above another—a practice which should be avoided, for the bees of the higher story frequently fall down and enter the lower hives, where they are killed. I place two hives on each side and one at each end. A door is cut out at each hive 2 feet by 1 foot 6 inches, and it shuts close to the front of the hives, preventing the bees lying out between the house and hive. I may state that the house is boarded to the ground to prevent the wind drifting the bees if they happen to fall when coming close to the hive, as there are more bees lost in spring close to their hives than at a greater distance, for the cold benumbs them at once. To prevent this, I take care to have all round the hives well strewn with dry ashes, &c.—A LANARKSHIRE BEE-KEEPER.

Café au Lait.—The French are justly celebrated for this breakfast coffee, which may be made as follows:—Use an infusion,

of double the usual strength, and when clear, pour it into the breakfast-cups, which have been previously half or three parts filled with boiling milk, sweetened with loaf sugar.—(*Prairie Farmer*.)

OUR LETTER BOX.

BATH AND WEST OF ENGLAND POULTRY SHOW.—Mr. Pitman says, "Our entries close next Saturday, the 16th. Specimens will be received up to a late hour on Saturday, the 6th of June, and judging commences (open, under certain restrictions necessary for the comfort and independence of those important officers) on Monday, the 8th of June."

COCHIN-CHINA HEN WITH DISEASED LIVER (*An Amateur*).—The lumps in and upon the liver were ulcers, and when a bird becomes so organically diseased we know of no treatment likely to restore it to health. In the case of a very valuable bird being so affected it might be worth while to try what a daily dose of calomel would effect.

HENS FOR EARLY SITTING (*J. W.*).—It is not the property of any particular breed to sit early. It is the result of calculation, and may be arrived at with almost the same certainty as an ordinary addition. It is the question, that immediately follows the frequent query as to the breed that will lay best in the winter. That which lays best in the winter will sit earliest in the spring. They follow as naturally as manhood and childhood. As soon as a hen has laid her number of eggs, the course of nature makes her anxious to sit. Those, then, who wish to have January chickens will be careful to keep early pullets of the previous year, which will begin laying in October. They will want to sit in December. This can be done only with pullets. Their first laying is a question of age, after that they are creatures of routine and season. Your feeding is bad. Rice is the worst food there is. Indian corn and meal may do for a change, and may be given beneficially once or twice per week, but not oftener. No fire or artificial heat is necessary for healthy fowls. Dorkings are excellent sitters. Most fowls sit well, but all are not good mothers.

EGGS MOST-FLAVOURED (*T. J. H.*).—When an egg is first laid the shell is soft, and capable of transmitting a taste or odour from without to its contents. Its flavour is also affected by any particular food, as garlic, onion, malt. It seems to have a peculiar aptitude for acquiring the taste and smell of hay, moss, sawdust, and the like. The best bottom for a nest is a sod of grass. Shavings are likely to communicate a flavour. It may be that the taste of which you complain arises from some food they find in the wood, possibly grubs or insects harboured by the moss at the roots of the trees. If it be so, it will be only temporary. Let your hens have sods of grass at the bottom of their nests, and we do not think you will have any lasting complaint against their eggs.

COCHIN-CHINAS' FEET TURNED INWARDS (*Clarence*).—It is difficult to assign a cause for the turning-in of the toes of Cochins. Part of it is natural. They have short toes, and the middle ones of both feet turn inwards. In some cases they are almost web-footed. A very hard and impenetrable flooring to the house may have its influence, inasmuch as the nails that would enter into the loose earth or gravel, and which turn downwards, are compelled to turn sideways. Stones, bricks, or boards will cause this. The gravelled run may not be altogether guiltless if it is hard-surfaced like a garden path. We advise you to put up perches within 18 inches of the ground. We have no doubt that will partly cure the evil. It would not affect the laying unless it interfered with the health of the birds.

BANTAM LAYING SOFT EGGS (*Hibernicus*).—The soft eggs and the feathers shed from the neck, we consider evidence that the hen's food is too stimulating. We should give her a dessert-spoonful of castor-oil, feed her for a time on mashed potatoes mixed with a little barleymeal, let her have plenty of lettuce leaves, and take care that she has free access to plenty of limy rubbish.

DISEASED PIGEON (*A New Subscriber*).—Your Pigeon is "going light," to use the fanciers' phrase. This depends on some internal organic cause and is rarely recovered from. Fantails are especially liable to the inconvenience alluded to. You are right as to the cause.

CANARY CEASING FROM SINGING (*Old Deer*).—The only causes we are aware of which would account for a bird not singing are either being too fat, having moulted the second time through cold, being too old, or having been used too often for breeding. The first-mentioned is most probably the case with your bird.

AUSTRALIAN PARROQUET (*E. M.*).—We find that No. 50 is out of print. Apologising for the trouble given, we reprint from that Number the information you ask. "The Australian Grass Parroquet breeds freely in confinement in this country. The cage should be square, of a middling size—2 feet 6 inches by 2 feet by 15 inches, with wire front only. Place at one end a rough box about 18 inches high and 7 inches square, covered with dry moss to represent an old stump, and having a hole large enough to allow the birds to have easy access. Place a tray or half a cocoa-nut shell inside, containing the nest already shaped, composed of dry moss, grass, and wool, similar to what Canaries build with, with some loose in the cage. Place the cage in a retired situation. Feed the old birds on canary seed; when they have young add boiled egg, millet, and mawseed, and when long grass is in seed let them have a bunch of it hung up. The price is about 25s. per pair. I do not know of any instance of Love Birds breeding in confinement."

—W. G.
LIGURIAN BIRDS (*J. R., Penzance*).—Write to T. Woodbury, Esq., Mount Radford, Exeter.

LONDON MARKETS.—MAY 11.

POULTRY.

We have a good supply of poultry for the time of year, but not more than an average. Trade is, however, so bad that it is sold with difficulty at a slight reduction.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 66.8° and 44.2° respectively. The greatest heat, 89°, occurred on the 22nd, in 1847; and the lowest cold, 30°, on the 19th, in 1854 and 1856; 20th, in 1853 and 1856; and 24th, in 1854. During the period 154 days were fine, and on 98 rains fell.

ORCHARD-HOUSE MANAGEMENT, AND CAUSES OF FAILURE.

MOST lovers of horticulture seem to be drawing their attention to the culture of fruit trees in pots under glass, or, as some people call it, the "Rivers system of growing fruit." That such a "system" is interesting, no one will deny; but few people seem able to make it profitable. I will, therefore, endeavour to

show some of the causes of failures, and to point out to amateurs several little rocks on which so many have been wrecked.

As glass is very cheap, a rough but convenient orchard-house can be put up for a small sum. This, I believe, has induced many people (a good part of them clergymen) to purchase Mr. Rivers' book. In that book they find pictures of the author's pet plants beautifully laden with fruit. This tempts them to get an orchard-house; they decide on having one. Well, the house is built, the trees are bought, and now comes the work of potting. And how is this important operation performed? Very often in such a manner as described by "F. Chitty."

That operation being completed, the trees are, most likely, arranged in their respective places, and the owner views them with a degree of pride. Perhaps they are good-sized trees, and have blossom-buds. These as the season advances will be expanding. Then comes the setting of the fruit—a result almost certain, providing the trees have abundance of air, and the roots are kept tolerably moist.

Perhaps the fruit set very thick, and, if they be Peaches, Nectarines, or Apricots, will require thinning. But the amateur does this very sparingly, leaving after the final thinning perhaps three dozen fruit on a tree not capable of bringing half that number to perfection. The result is a large crop of small ill-flavoured fruit.

Thinning of the young shoots of Peaches and Nectarines is to the beginner a rather difficult operation, though Mr. Rivers would have it appear a very easy matter. Most people thin them too sparingly, leaving a mass of young wood, which, unless the weather be very favourable, cannot be properly ripened. Some, however, thin too severely, thereby robbing the fruit of its nourishment, and destroying the fruiting-wood for the following season.

I know some gentlemen who do all their orchard-house work themselves, and I know others who leave their

trees entirely to the tender mercies of their "groom and gardener," who, as one of your correspondents remarks, "knows very little of either business," and to whom the trees are a "great nuisance," as they give him extra work. In such cases the poor trees are likely to suffer for want of water. Perhaps the man is ordered to give them liquid manure, and he does it with a vengeance, bringing it thick and strong from the cow or pig yard unstrained, and unmixed with anything. The effect of this is not long in making its appearance. I once saw some very fine Peach trees which had lost nearly all their leaves long before the fruit began to ripen. On looking at the soil, I saw they had been watered with strong liquid manure. This was, undoubtedly, the cause of the leaves falling so early.

Growing too many sorts of fruit in one house is a very bad practice, and is often the cause of much dissatisfaction. Peaches and Nectarines will be found to do best by themselves. Apples, Pears, and Plums may go together. Apricots and Cherries do well together; and for all these fruits (except Peaches and Nectarines), tiffany-houses will be found most suitable.

A gentleman once asked me to look at his orchard-house trees, which he said were in a very unhealthy state, the cause of which he could not discover. I found the trees as he described them: they were very free from insects, and the surface soil seemed nice and moist. I tapped the pots, and the sound produced told the cause of sickness—the trees were dry at the roots. They had been potted too loosely, the body of the pots containing only a few crumbs of dry soil. The watering seemed to have been performed on the "little-and-often" system, just to keep the surface moist. And what is the result of all this mismanagement? A complete failure. Those visions of fine ripe fruit have never been realised, and the orchard-house is condemned.

Some, however, are more fortunate. I, for one, have been pretty successful; but success cannot be attained without exertion, for every one who has had the management of orchard-houses will admit that the inmates require great attention compared with the same kinds of trees on the open wall. But the labour is not thrown away, for the reward will be in proportion to the attention bestowed.

To those who are about to build an orchard-house I would say, Have a lean-to, and, if convenient, against a brick wall. With regard to the shape of trees, close pyramids are by far the best. When the trees are received from the nursery their roots should be examined, and if found at all naked should be cut back pretty close. Some compost should then be ready, consisting of two parts the top spit of an old pasture, one part road scrapings, and one part decayed cowdung. This will be suitable for most fruit trees.

The compost being ready, some pots should be selected. The relative proportions of these and the trees should be considered; and if they are of the ordinary kind, the apertures in the bottoms must be enlarged, leaving only just a bearing for the crocks. These should be long and

narrow, and placed so as to leave room for the emission of the roots of the tree. Some rough stuff, such as pieces of decayed turf, may then be placed on the corks, and then some compost, and made pretty firm; and over that the tree should be placed, just in the centre, care being taken to keep the surface roots about 2 inches below the top of the pot. The compost should then be put in a little at a time, ramming it firmly with a stick as the work proceeds, finally filling up to within an inch of the top of the pot. The whole should then receive a good watering, and the stems (but not the bearing-wood) be washed with a composition formed of one pound of soft soap, two ounces of tobacco, and a little flowers of sulphur, to which must be added as much boiling water as will form the whole of the consistence of paint.

Supposing the above to be done about the middle of February—which is the best time for potting—the trees may be placed in their summer quarters, and the young shoots cut back according to the desired shape of the tree and the strength of the shoots. After that they will require very little attention till the blossom-buds begin to expand. Watering must then be gradually increased, and abundance of air given; in fact, when the trees are in bloom, the shutters need not be closed, except in case of frost or fog.

When the fruit is set, the trees should be syringed with soft water about 4 P.M., of every warm sunny day, at the same time closing up the front shutters of the houses, but leaving an opening at the top of each end. As the weather becomes warmer the houses must be left open longer, and after the 1st of June they may be left open altogether.

The Peaches, Nectarines, and Apricots will most likely require thinning, and supposing the trees old, eighteen fruit may be left on each, these after the lapse of twenty days to be reduced to nine on each. The following season double that number may be allowed. The other hardy fruits seldom require thinning.

When the young shoots of the Peaches and Nectarines have made four leaves, every third shoot should be removed, and after another fortnight every fourth shoot should be taken off with a sharp knife, and the tips of the remaining ones pinched off, as also the tips of Apricots and Plums.

It is, however, quite impossible to give directions for thinning the shoots in all cases, as sometimes the trees make very little wood, and then allowance must be made. One important point is, to get the fruit near to the leaves.

The Peaches and Nectarines will soon be making fresh shoots, and these must be pinched back to the sixth leaf, and so on with the next. I have found three stoppings quite sufficient for the whole season, as incessant pinching causes the tree to produce a superfluity of blossom-buds, causing a scarcity of leaf-buds.

One stopping of the shoots will generally be found sufficient for Apples, Pears, Plums, and Apricots, except in very strong-growing trees. I consider that cleanliness, plenty of air, light, and moisture, are the chief points to be remembered, for the absence of either of these will cause a failure.

When the fruit is ripe and gathered, every attention must be paid to the ripening of the young wood, by keeping the house dry and warm and gradually withholding water from the roots. When the wood is ripened the trees may be put close together in a corner of the house, and the borders cleaned to receive Chrysanthemums, Lettuce, Endive, Parsley, and many other things that require a slight protection from the frost.

In the latter part of February the trees may be arranged for the summer, and the stems be washed as before directed. The surface soil should then be removed, and the space filled up with a dressing of decayed dung. I do so three times during the growing season.

I have not seen any "miniature fruit trees," such as Mr. Rivers describes, but I intend to get some. In Japan the "art of dwarfing trees" is one of the chief points in ornamental gardening. When Lord Elgin was in that country, a box was offered to him, in which were flourishing a Fir tree, a Bamboo, and a Plum tree in full blossom. The size of the box was 4 inches long, 1½ wide, and 6 high. The price asked was about £100.—G. G., Wells.

VIOLETS.

THE provincial gardener residing at a considerable distance from the great metropolis, and who visits it but seldom, cannot fail being struck by the endless quantity of good articles in the gardening way which he will see around him in all directions,

even in midwinter, or in the spring after an unusually severe winter, when the outcry far and wide is that everything in the Broccoli and Cabbage line has been destroyed. He will see cart-loads of these vegetables wending their way into the centre of the great city, while vendors of such things scattered all over the town present the same in more or less profusion; the price rather than the seeming scarcity is the only thing that betokens a limited supply. Other things as well as vegetables find their way into town, and certainly not the least attractive of the varied articles which form a considerable item in the trading transactions of street vendors is the flower which forms the subject of my present notes, and one which is carried through as extensive a period as any flower we are acquainted with.

"Violets, sweet Violets!" is an agreeable cry, the more so as being heard when the weather and other surroundings are anything but pleasing. Violets have attractions which even in a dull cheerless November day remind one that other senses as well as the one which appreciates the beautiful may be brought into operation. However fastidious the individual may be about smells, and the writer of this is one of that class, Violets are of the class of plants which every one admires, and a nice little knot of Violets is acceptable alike in a lady's boudoir and on the mantelpiece of the humblest cottager: it is, therefore, needless to make any apology for jotting down a few remarks on its cultivation.

Too often some out-of-the-way corner is the one assigned to this plant. Presenting little that is gay at a time when the parterre is a blaze of beauty, its merits seem forgotten at the time it most deserves attention, so that when the season for flowering arrives the result is not always satisfactory; for though the plant is very hardy, and will accommodate itself to most situations, there are some more favourable than others, and it is to these that we ought more particularly to direct our attention, and in a few words detail the practice most likely to produce a good result. At the same time it must be observed that some situations present natural advantages which it would be difficult to imitate, yet much can be done, and the plant, as stated above, is very accommodating. Nevertheless, it is not everywhere that it succeeds satisfactorily, and a glance at those where it does prosper may teach us how to manage it so as to procure a similar result; and, perhaps, the best way to consider the subject is to trace the plant to its wild state—the original British one inhabiting dry banks by the side of lanes and woods, where it blooms profusely in early spring.

The best situation both for the Neapolitan and double and single Russian Violets are those rather stiff soils overlying chalk, and where the plant has an opportunity of enjoying the free air, and not overshadowed by trees, especially evergreens. I am not sure but a slight shading with deciduous trees is beneficial rather than otherwise, as the plant is so liable to red spider in hot summers; and a partial shading from the hot midday sun induces the dew to remain longer on the foliage, and, consequently, renders the plants less injured by this pest. A soil too rich is more likely to produce leaves than flowers, so that manuring too freely is not advisable.

When a new plantation is wanted, it is best to make one as soon as ever the plants are rooted sufficiently to be taken off. The plant generally produces abundance of runners after it has done flowering; and to induce them to root freely, and quickly become plants, it is very good practice to sift some leafy mould or fine soil amongst the shoots, and, if the weather is dry, to water once or twice. Generally it is the end of May ere the young plants are sufficiently rooted to be taken off with advantage, when, the ground being previously well dug and prepared, they may be planted in rows about 18 inches apart, and allowing about a foot from plant to plant in the row. This planting ought to be done in damp weather if possible; and the little after-attention required during the summer is simply to remove any runners or suckers that show themselves. It is better to allow them to grow a little, and then cut them off, so as to encourage the main plant to form a head or crown well set with flowering-buds for the ensuing season. It is attention to this that makes a plant tidy-looking, and retains it in a condition fit to remove with a ball if wanted in autumn. Observe that a too frequent stopping all laterals or runners is not such good practice as letting them grow some length and then cutting them all back; for the pruning of the Violet is something like that of the espalier Apple or Pear tree—to cut off every shoot as it is found is more hurtful to the tree than allowing them to arrive at nearly their growth, and then removing them to enable all the

energies of the tree to go to the formation of flower-buds (in embryo) for the ensuing season. The Violet, though an herbaceous plant, may be treated exactly the same way, and with a like happy result.

Now, the above treatment, simple as it is, is not the only attention required during summer. The plant being very liable to red spider, means must be taken to counteract it if possible. For that purpose a mixture of sulphur and soot is about the best thing that we have tried, and when any of the leaves turn yellow it is often a sure sign that this pest is at work. A good watering when the atmosphere is moist will do some good, and when the plants are dry dust them well with the mixture mentioned above. The admixture of soot will render the colour more like that of a healthy plant, and the formation of flower-buds will go on more prosperously in proportion as the plant is healthy: by which is meant, that it is supposed to be maturing its tissue in proper time and not prolonging the season's growth, or becoming what may be called gross and leafy. We need hardly add that occasionally moving the ground between the rows is useful also during the early summer season, afterwards we expect the plant will occupy it all.

The forcing of the Violet is far from being at all times a successful operation. The plant is impatient of forcing as generally performed. It may, however, be forwarded considerably by gentle means, not the least being the well and early preparation of the plants the preceding summer, so as to enable the plant to have a period of rest ere it be excited again into growth; for if forced too early, leaves only will be the result. The best way is to prepare some plants as directed above, and in October take them up with a ball and plant them in an old Melon-bed that has a little bottom heat (but very little), remaining. The plants may be placed tolerably close, and with sufficient soil to enable the roots to have plenty to live upon while the plant is in the frame. We need hardly add that they must be near the glass; and if the position of the frame be one that it is advisable to keep orderly, the interstices between the plants may be paved with pebbles not larger than an egg. This will keep the flowers from being dirtied in the soil. A little watering at the time will be necessary, but will hardly be wanted afterwards. Violets may also be taken up and forced in pots, and they do pretty well that way.

Unlike many of the kinds of plants cultivated for appearance or use, this one has derived but little accession in the way of new varieties for many years. True, now and then an improved tree Violet is offered to the world, but it very often settles itself down to be the old sort in a better state of cultivation. Improvements on the single or Russian Violet are also announced occasionally; but they too often degenerate into the original. Therefore, without noticing the names of the great raisers of such things, a slight allusion to the kinds in most general use will be sufficient for this article.

First in point of importance is the old dark blue Violet, from whence one more than usually woody or leggy has been transformed into the tree Violet. This is, perhaps, the prettiest of all the Violets, and it has the advantage of presenting us with a few flowers almost during all the summer. It does not flower, however, so well in the winter; but when well grown and the plants well and early ripened, it often flowers in March when sheltered rather than forced. I believe there are improved varieties of it said to be larger; but they do not differ in any material point from the original.

Next to this variety is the Neapolitan Violet, a pale blue variety, more free of growth and better adapted for forcing. The habit of the plant is more spreading and requires more pruning to keep it in order. It is, however, less susceptible to red spider perhaps; but is, nevertheless, not more hardy than the others. It is, perhaps, better adapted to a light soil, and some insist that it is sweeter than the dark one; but this is doubtful. The stalks of the flower are, however, longer and bunch better, and contrasting with the others it is better to have both.

There are double white ones of both the above varieties; but the whites are not so generally admired, and the white Neapolitan is a poor one.

Next, therefore, in importance to the two named, and, perhaps, equal if not superior in point of utility to them, is the single Russian, which flowers in the autumn in the open ground, and through the winter if the weather be mild. This is, perhaps, the most popular of all the Violets; but, unfortunately, it is seldom so well cared for as the double ones, although from the fact of its supplying us with little bunches of Violets at a season

when they are not to be had elsewhere, it deserves more attention than it often receives. Some improved varieties of this have from time to time appeared, an extensive grower in the west of England having issued some new varieties of it. It is very accommodating, and is too often ill-treated in respect to the situation it is planted in. Its flower-stems are, however, short, as might be expected from its flowering in midwinter. Nevertheless, with this drawback it is exceedingly useful. I am not aware of a white variety of this kind, but it is not unlikely that there may be one, as there is a white amongst the wild ones which this much resembles.

Besides these there is an old pink variety, double and pretty but it lacks in a measure that agreeable smell which gives the Violet pre-eminence of everything—the Rose only excepted. There are some other subordinate varieties, but the above sufficient to give the amateur an idea of what they are, and also to enable him to cultivate them successfully.—J. R.

THE ROYAL BOTANIC SOCIETY'S SHOW.

MAY 13.

AFTER a long course of dry weather both farmers and gardeners were anxiously looking for rain, and they had their wishes gratified on the day preceding the Show, when rain fell in considerable quantity. The advent of rain, however, was not hailed by all with feelings of unmixed delight—plants had to be packed on the evening previous to the Show, and tarpaulin coverings for vans, and mackintoshes and umbrellas for man, were in great requisition, whilst dire was the consternation of many of the intending lady visitors at the prospect of a dripping wet day that would mar all pleasure, as well as sundry new silks with fine French names, as to the meaning of which we are in a state of misty uncertainty. But the fates were not adverse, for, with the exception of one or two heavy showers, there was nothing to detract from the enjoyment of one of the finest exhibitions which have been seen at the Regent's Park. The mass of colour which lay before the eye on entering the large canvas-covered space where the exhibitions are held was imposing; the green turf gave relief, whilst one was always discovering fresh beauties in nooks and recesses that had escaped the first glance. The Azaleas were superb, the stove and greenhouse plants splendid examples of skilful cultivation, and the more modest-looking Heaths generally well grown, as well as very attractive.

Of stove and greenhouse plants several excellent collections were brought forward for competition in the different classes. In that for sixteen Mr. Peed, gardener to Mrs. Tredwell, Norwood, had a fine evenly-grown *Tetratheca ericæfolia*, *Leptodactylon californicum*, *Leschenaultia biloba grandiflora*, *Aphelaxis sesamoides rosea* and *macrantha purpurea*, *Pimelæa spectabilis* and *decussata*, *Chorozema Lawrenciana*, *Franciscea confertifolia*, *Erica depressa*, two Azaleas, and some other plants, all of which were well grown. This collection was considered the best in the Amateurs' Class. Mr. Baxendine, gardener to W. Smallpiece, Esq., Guildford, came next; and among his plants were *Chorozema Henchmanni* covered with bloom, *Stephanotis floribunda*, *Rhyncospermum jasminoides*, *Hovea Celsi*, *Aphelaxis*, &c.

Other collections less numerous came from Messrs. J. & J. Fraser, of Lea Bridge; Jackson & Son, of Kingston; J. & C. Lee, of Hammersmith; and A. Henderson & Co.; and among amateurs from Mr. Green, gardener to Sir E. Antrobus, Bart.; Mr. Ingram, of Reading; Mr. Page, and Mr. Wheeler. Among these there were excellent specimens of *Leschenaultia intermedia* and *biloba major*, *Acrophyllym venosum*, *Boronia serrulata*, *Eriostemons*, *Polygala Dalmaisiana*, several Azaleas, the beautiful *Clerodendron Thomsonæ*, *Chorozemas*, *Erica Cavendishii* several *Aphelaxes*, *Rhyncospermum jasminoides*, *Hedera*, *Medinella magnifica*, *Labichea heterophylla*, *Allamanda grandiflora*, *Franciscea*, and some other plants which it would be tedious to particularise.

Azaleas, as already remarked, were superb, those of Messrs. Veitch and Mr. Green being particularly fine. Among the varieties exhibited by Messrs. Veitch were *Iveryana*, *Feltoni*, *Magnificent*, *Exquisita*, *Juliana*, and *Barclayana*; whilst Mr. Green had *Alba magna*, *Chelsoni*, *Glory of Sunninghill*, *Triumphans*, *Broughtoni*, *Juliana*, and *Magnificent*. *Arborea purpurea*, from Mr. Turner, was a mass of bloom; *Admiration Optima*, *Magnifica*, *Broughtoni*, and *sinensis* from the same

exhibitor were also very striking. Excellent collections also came from Messrs. Fraser and Lane & Sons.

In Cape Heaths, of which there were several fine collections, Messrs. Jackson had the best in the Nurserymen's Class. The kinds consisted of *Bergiana*, *depressa*, *fastigiata lutescens*, *ventricosa tumida* and *magnifica*, *fastigiata lutescens*, *florida intermedia*, and *tricolor dumosa*, all of which were handsome specimens. Mr. Rhodes, of Sydenham Park, was likewise a successful exhibitor with a fine *Erica Cavendishii*, *ventricosa coccinea minor*, *Victoria Regina*, and nice plants of several other kinds. Mr. Peed contributed large plants of *Cavendishii* and *florida*, together with *coccinea minor* and *depressa*, both of which were in beautiful condition. Mr. Page and Mr. Baxendine also came forward with well-grown plants, and were both successful in gaining prizes.

Roses in pots constituted a brilliant feature in the display, and as examples what can be done by pot-culture were everything that could be desired, the plants being of great size, healthy, and covered with bloom. Messrs. Lane and W. Paul in particular distinguished themselves, the former with Charles Lawson, Comtesse Mole, Baronne Prevost, Léon des Combats, Chénédolé, Souvenir d'un Ami (a remarkably fine plant), Paul Perras, Jules Margottin, Gloire de Dijon, and Coupe d'Hébé; and the latter with Sénateur Vaisse, Paul Ricaut, Lord Raglan, Madame de St. Joseph, and several of those already mentioned. Mr. Francis, of Hertford and Mr. Terry, gardener to C. W. Giles Puller, Esq., M.P., Youngsbury, likewise exhibited well-grown plants.

In *Pelargoniums* Mr. Turner, of Slough, took the lead with twelve large and handsomely-grown plants in eight-inch pots, and which were a mass of bloom. Fairest of the Fair in particular was lovely, and scarcely less so was Sunset. The other varieties were Ariel, Picnic, Virginie (Miellez), a glowing scarlet; *Desdemona*, *Empress Eugénie*, *Rose Celestial*, *Beadsman*, *Sir Colin Campbell*, *Candidate*, and *Lilacina*. Messrs. Fraser, coming in second, had in addition to several of those already named Mr. Marnock, Governor General, *Leviathan*, and *Osiris*; and in the Amateurs' Class Mr. Bailey, gardener to T. T. Drake, Esq., *Shardeloes*, and Mr. Weir, of Hampstead, showed nice collections.

Fancy varieties came from Mr. Turner, Messrs. Fraser, Mr. Bailey, and Mr. Weir; and many of the plants were of great diameter and literally covered with bloom. The principal varieties were *Arabella Goddard*, *Delicatum*, *Roi des Fantaisies*, *Acme*, *Queen of the Valley*, *Clemantine*, *Clara Novello*, *Modestum* (a charming variety), *Carminatum*, *Cloth of Silver*, *Negro*, and *Lady Craven*.

Cinerarias were not remarkable; indeed, several of the plants, as far as cultivation was concerned, were unworthy of exhibition. The best came from Mr. Lamb, of Southall, and Mr. Pointon, gardener to C. Perry, Esq., *Castle Bromwich*.

Orchids were shown in abundance, and among them were several fine examples of *Cattleya Mossiae*, *Lycaste Skinneri*, *Phalænopsis amabilis* and *grandiflora*; *Saccolabium guttatum*, *refusum*, and *præmorsum*; *Cypripedium barbatum*, and other species; *Vanda tricolor* and *suavis*; numerous *Ærides*, *Dendrobiums*, and *Oncidiums*; *Lælia purpurata* and *Bryasiana*. A fine pan of *Orchis foliosa* from Mr. Bullen was, however, one of the most remarkable. The principal exhibitors of this class of plants were Mr. Baker, gardener to A. Basset, Esq., Stamford Hill, who took the highest position for a collection of twenty species; Mr. Bullen, whose plants were also fine, but in ugly, open-sided tubs; and Messrs. Page, Wooley, Peed, Smith, of Syon, and Wiggins, of Isleworth.

Collections of mixed flowering and fine-foliaged plants came from Messrs. A. Henderson & Co., and Lee, and exotic and British Ferns from Mr. Lavey; Miss Clarkson likewise bringing forward a good collection of the latter.

Of cut flowers there was a plentiful display, especially Roses, of which beautiful masses were contributed by Messrs. Lane, Paul & Son, and W. Paul; the last showing among others, Lord Macaulay and Lord Herbert, two new varieties of great merit.

Stands of Pansies came from Messrs. Downie, Laird & Laing, Turner, Dean of Bradford, Shenton, August, and James; of Verbenas, from Mr. Treen, of Rugby, and Mr. Turner, who had also Tulips, and several pots of President Strawberry.

Of miscellaneous objects, decidedly the most interesting was *Napoleona imperialis*, a flowering branch of which was sent from Syon. Mr. Bull brought a large collection of new and rare plants, including the extremely curious *Pogonia discolor*, *Areca*

dealbata, and others which will be noticed in another column. Mr. Standish had two beautiful Clematises, one of them having double white flowers of very large size; has been provisionally named *C. Fortunei*; the other, which is single and of fine violet hue, has been named *Clematis florida Standishii*. Both of these are decided acquisitions. Mr. Turner had Louise Von Baden, a beautiful white Azalea; Mr. Holland, a very superior white and magenta *Petunia*, called *Royalty*. Messrs. Veitch had *Ourisia coccinea*, the crimson flowers of which were very effective; *Rhododendrons* Mrs. Buller and Princess Alice, the lilac *Stenogastera multiflora*; *Browallia Jamesoni multiflora*, from Ecuador, with numerous orange-yellow flowers; and a *Melastomad* called *Melastoma (?) argyoneura*, with very ornamental rugose olive green leaves, which promises to be a great acquisition. Besides the above there were several seedling *Pelargoniums* shown by Mr. Turner, and Mr. Hoyle, of Reading.

AN ORCHARD-HOUSE IN THE HIGHLANDS.

THE following note from a gentleman who, in conjunction with, doubtless, a clever gardener, manages his orchard-house well, will, I trust, prove interesting to your numerous readers.—T. R.

"Dear Sir,—

"Perthshire, May 1, 1863.

"I observe a great discussion going on in THE JOURNAL OF HORTICULTURE as to the merits of orchard-houses. I have never wished to draw myself into the contest, and have, therefore, kept clear of it; but I think it is in justice to yourself to say that from seeing your houses at Sawbridgeworth and their success there, that I was induced about six or seven years ago to put one up, and I may safely say I have never regretted having done so. I have always had first-rate crops, and that without any fire heat and in a cold climate. Last year, notwithstanding the inclemency of the season, I had a most splendid crop of Peaches, Nectarines, Figs, Grapes (Black Hamburgs), Tomatoes, and Capsicums, to say nothing of the most beautiful Strawberries of the highest flavour, and finer than any we can grow out of doors. The earliest ripen about the 15th to 20th of May, and with successions of later kinds last till the out-of-door crop comes on about the end of June or beginning of July. A gentleman who is a judge of fruit tasted some of my orchard-house Peaches, and pronounced them superior to any he had ever tasted off a wall. Many of them measured over 9 inches in circumference. This year my trees in pots are again loaded with fruit, and are perfect pictures of health and beauty. The average crop I allow is two dozen each tree.

"To show the great advantage of glass without fire heat in a northern climate, my Vines this season were as far forward on the 15th of April as I observed them in the vineyards in the Island of Fano, near Corfu, on the same date of which I have a note.

"I may state that my orchard-house is 50 feet by 15, a lean-to, with brick wall at back and terraces; the Figs and Vines being on the upper terrace and next the wall.—PERTHSHIRE."

FLUES VERSUS HOT-WATER PIPES.

In your Number for the 5th, at page 326, "J. E. L., Jun.," and Mr. Thomson at page 330, call in question the correctness of my statement in page 211 on the above subject. I might have been more explicit, but fearing to take up too much of your valuable space I was as brief as possible. The length of my flue is 15 yards; the cost per yard, 3s. 0 $\frac{1}{2}$ d., as follows:—750 building-bricks and mortar, and labour, 26s.; fire-brick covers, 20s. My flue required no foundation, it being built on the solid; and although I stated my flue was 12 inches deep, yet near the furnace it is only 9 inches, allowing a rise at the further end of 6 inches, or 15 inches deep. Taking the middle depth 12 inches, only allowing a depth of flue 9 inches, filling up the space with rubbish; the heating surface of my flue is as much as can be, being both sides and top. Any circulation of air underneath the flue, as "J. E. L." recommends, would be injurious rather than useful, as the soot and dust settling in the bottom prevent any heat getting through the tile, and would be very much more likely to leak at the joints through settling or other causes, and would not be at all firm, and be also costly and useless. My article at page 211 was written to show the difference of cost of the two plans: consequently, I only gave the cost of flue. The furnace, the bars, and door would be about the same as required.

for boiler, less of either. My chimnies are built in the back wall of the house. I think "J. E. L." would have some difficulty in keeping up a proper heat in a house 40 feet by 15, with only a flow and return pipe of three-inch water-piping. Neither does he state cost of stays for his piping, which are always costly. In further reply to Mr. Thomson, page 330, the above will answer his question of furnace-bars, &c. Dampers are great evils in greenhouses or vineries, causing leakages in flues, &c. From the annexed drawing he will see arches are unnecessary,

A Flue.
B Border for Vines inside house.
C Border outside the house.

D Three-inch space between flue and border to keep Vine roots from the hot flue.

as the Vines when they have filled the space inside the house may find nourishment outside. If I were building a house 110 feet long, I would build furnace, flue, chimney, and all at £10 less cost than Mr. Thomson estimates.—E., *Burton-on-Trent*.

A GOOD BOILER.

IN replying to Mr. Robson's question for particulars of a good boiler, I imagined that I had given sufficient details to enable him to judge of the capabilities of my Truss boiler; and I am sorry that I did not give a more explicit detail, which I should have done had I properly contemplated the probability of appearing in print.

I cannot possibly estimate the cost exactly, as the summer work was almost entirely performed by the refuse and cinders from the house. For winter work, as a greater heat and quicker circulation were required, I have been obliged to use coke, and from October the 23rd to the end of April I have consumed eight chaldrons, and the cost has been for twenty-seven weeks about 4s. 4d.

The cubical contents of the different structures are about 5600 feet, and it has heated a small stove, greenhouse, conservative-house, and an open-air tank, and with heat to spare. My boiler has to work under many disadvantages, as the main flow and return between the boiler and into the upper house, including the perpendicular rise of about 12 feet, are only two-inch pipes, and there are so many turns and returns necessitated by my various contrivances that I have no hesitation in saying that three times the amount of work could be done in a range of houses on level ground, and for an amateur no boiler can be more satisfactory. I have often lighted the fire myself—in fact, I think that I can do it even better than my man, and in less than an hour the return-pipe to the boiler shows a rapid circulation.

I observe that the printer made a slight error in calling one of the divisions of the upper house a "coach-house," which will appear curious to some of your readers. It should have been "Cactus-house."—C. M. MAJOR, *Cromwell House, Croydon*.

PROFUSION OF STRAWBERRY BLOOMS.—My gardener told me a few days ago, that he had mentioned to some friends that he thought some of my Strawberry plants last year had as many as three hundred fruit-blossoms on each plant, and that his friends had laughed at the assertion. I at once took my gardener to the Strawberry-bed (composed of several kinds), selected a moderately fair-looking plant in full bloom, and on

counting the blossoms found that there were four hundred and twenty-eight! I have no doubt that I have plants with five hundred blossoms. I merely mention the above in case you should think it worthy of notice.—J. H., *Binstead, Isle of Wight*.

HEATING GREENHOUSES.

THERE is not the least doubt but the hot-water system is the best when there is much glass to be heated; but for an amateur who has a greenhouse, say 14 feet by 10 or 20 by 12, I certainly think that nothing can be better than the ordinary flue or pipes. I have a house (a lean-to), it is 14 by 9, 10 feet high at back, and 5 feet in front. It is heated by means of a furnace which is entirely inside (the door of the furnace of course being outside), so that every bit of heat is in the house. There are 2 feet of brickwork from the furnace, and into the end of this brickwork the first stone glazed pipe is placed; then follow the other pipes, which run along the back and out into a chimney at the other side of the house. The joints of the pipes are mortared. On the top of the brickwork I place a wooden tray 2 feet square, 3 inches deep, filled with coal ashes, on which I forward different things for spring cuttings and also seeds. *Calceolaria* cuttings will strike very fast in December and January—much better, in fact, than in July or August.

When the fire is lighted, I always find the pipes are warm in about five minutes, and in half an hour the house is quite comfortable. It burns but little fuel—even in the most severe winter a half-cartload of breeze will be quite sufficient, and it will keep in from ten at night till seven in the morning. Cost of bricks and mortar, 2s.; furnace ironwork, 5s.; seven glazed six-inch pipes, 4s.; total, 11s.

The pipes if cleaned well out in September, will go till September again without requiring a second cleaning.

If you think this heating account worth noticing in your Journal, no doubt some of our amateur friends may be induced to try my plan, which will no doubt answer their purposes quite as well as it answers mine.—J. B.

[Perhaps your estimate is fully low enough; but you just confirm Mr. Robson, and Mr. Fish in "Doings of the Week," that small solitary houses are cheapest heated by flues. Of course, they too will be expensive if built on raised arches and all the rest of it, with huge tiles for bottoms. For a little greenhouse we should do as you have done; or, if bricks all round, we would have a good concrete bottom on a hard earth bottom, two bricks on edge, and a nine-inch tile on the top. We thus heated a small house by running a small flue 6 inches wide below a floor, the tiles covering forming part of the floor; and it cost little more in shillings than a gentleman offered to do it for by hot water in pounds. In speaking of the cost of hot water, and also of flues, everything should be stated. For instance: if we go to one of our advertising emporiums, select a boiler, suitable pipes, &c., and put it up with our own men, the expense must be and ought to be different from bringing men from a distance to do the work.]

THE USES OF AN ORCHARD-HOUSE.

IT may be interesting to some of your readers to know the routine of culture that has been observed in a house erected by me here some twenty years ago, and which may be said to be the prototype of Sir Joseph Paxton's recently patented "Hot-houses for the Million." My house is 50 feet long, 14 broad, 7 high, and is span-roofed, facing east and west, the ends of course north and south, and it is properly heated with hot-water pipes.

The house is planted with Vines and Peaches planted inside close to the wall-plate a foot only from the ground. These are trained in the ordinary way on trellising of wire. But besides these I grow various other descriptions of garden produce. I first plant dwarf Peas, sow Lettuce, Radishes, and Onions; plant Asparagus, Sea-kale, and Rhubarb, and introduce Strawberries on shelves, the sorts I grow being Keens' Seedling and British Queen. As all these things grow they begin to occupy a large amount of space; but as some require to be consumed, and the Strawberries when set require greater heat, and as the foliage of Vines and Peaches becomes too full for the latter, I take out all my Strawberries, regard being had to their being well set, into the vinery, where they swell and ripen well. As soon as my green Peas are nearly or quite over, my Kidney Beans, first brought forward in

60-sized pots, are planted-out in the usual way where the Peas have performed their office, and by this means I have a much earlier crop than I should have done out of doors. The Beans will not be too much shaded, but bear well. Having disposed of them, my next proceeding is to introduce Melons in the common soil of the house, and as long as the sun shines with sufficient force I gather sweet Melons. I have seen them in the fields in Italy, and conceived that with the atmospheric heat of our vineries the soil would be equally warm; and I have succeeded without any other stimulus. Cucumbers grow too fast. I have introduced Mushroom spawn, but obtained few, and I may say I have failed there, and I do not know how it was. I will add, I have succeeded with Figs and Oranges in pots, as they both love a little shade.—JOHN STOVELD, *Stedham Hall, near Midhurst.*

WHAT FLOWERS THINK OF IT.

A DIALOGUE BETWEEN MR. HOLLYHOCK AND MISS ROSE.

HOLLYHOCK.—Well, Rose, do tell me what is going on over there. Since Mr. Cuttings banished me from the border I can see and hear nothing. Summer's coming, though, and then you know eight feet o'ertops the fence by two—unless, oh! horror of horrors! that man decapitates me for exhibition!

ROSE.—Well, stately old friend, I wonder not at your annoyance, once the glory of the flower garden, and now in durance vile beneath this gawky fence; but we all have our troubles. There was a time in which I was held in higher repute before these bold spindle-shanked hybrids were all the rage, sticking their gaudy tops above the heads of the dear children. Well, there's a grand display on the parterre, as they call it, a geometrical digging (copied from the panels of the hall-door, so a bird told me), filled with—what do you think?

HOLLYHOCK.—Perhaps Roses, and Hydrangeas, and Lilies, Agapanthus, Carnations, Pinks, Dianthus, Primroses, Wall-flowers, and Pansies.

ROSE.—Oh, no! you speak of times gone by, when the borders were always new, from Christmas Rose to Chrysanthemums—right out of Winter's snow to Autumn's golden leaf—"a thing of beauty and a joy for ever."

HOLLYHOCK.—Well, what? Do tell me, Rose.

ROSE.—Prepare yourself for the worst, my dear old friend. Each bed is filled with the same sort of flower, all huddled so thick together that not a bit of the rich black mould can be seen, and the plants so crowd each other that all form and contour are lost.

HOLLYHOCK.—But what, friend Rose, do they plant in this way? Only mean things whose foliage in colour and form is a disgrace to them.

ROSE.—Well, no. Scarlet Geraniums for one thing—great blazing patches of blood-red, whose fiery hues lend a double fervency to the dog days, and then ere the second frost are a black putrid mass.

HOLLYHOCK.—Why, what does the squire think?

ROSE.—Oh! I think he's sickening of the new-fangled notions. The houses crammed full of "bedding stuff," as they call it, half the year; and the trouble and fuss of coddling the precious cuttings from September to May.

HOLLYHOCK.—Well, I thought that was the squire's opinion. Last summer he came this way frequently, and he did me the honour once to say that I am "a grand old flower still." Of course, I made him my stateliest bow. But what of the lady? Does she take as much delight in it?

ROSE.—Oh, no, who'd go walking among a lot of nursery-beds, between long rows of Tom Thumbs, and weedy Verbenas, and Calceolarias? Why, it would be thought madness. The parterre is not meant for close inspection, 'tis to be seen only from particular points—the drawing-room windows or the corner of the terraces, for instance. No, they don't go nearer or the design is lost! It's a great showy advertisement, a sham, a monstrous violation of common sense, and as such must be in direct opposition to good taste. Who cares to linger and stoop over great patches of scarlet, and yellow, and blue—scarlet, yellow, and blue *ad nauseam*?

HOLLYHOCK.—Hurrah! but this is not only pandering to the rage for display, this sensation gardening, but it is bringing disgrace and ruin upon the gentle craft. Gardeners may talk of skill in arranging colours, and be mysterious about harmonies and management of bedding stuff, or twaddle about edgings,

and ribbons, and pincushions, and "beds to match;" but the public are getting tired of the thing, and will come back ere long, I think, to ask our help. What think you, Rose?

ROSE.—Well, friend, you're warm somewhat. The flowers I see are brilliant in colour and some of elegant form, 'tis true, though tender things, and not well fitted for our climate; but 'tis the planting that's mainly wrong—this system of massing, as they call it.

HOLLYHOCK.—Yes, yes; but they're mean dwarf things generally, and cannot stand our climate. Why, the beds are bare above six months in the year!

ROSE.—Yes; but you forget the brilliant idea of clinkers and broken glass, and many-coloured stones!

HOLLYHOCK.—At which our squire is gravelled.

ROSE.—And evergreens. But who cares for the parterre? Why, all our squire's family rush along this way. How eagerly they run to Will Haylock's cottage garden, and beg a bunch of Wallflowers, Cloves, and Honeysuckles, and now and then a sprig of his crimson China.

HOLLYHOCK.—Which Mr. Cuttings pooh-poohs, no doubt. Well, well, this is but the opposite extreme. I once had the honour of being staged at Sydenham, and was heartily ashamed of myself, leaning for support like a drunken soldier. The idea of a Hollyhock's head stuck in a potful of sand to be gazed at and admired was only on a par with the barbarous custom of clipping and shaving trees. But what was still worse, a pettifogging fellow came with small bone tweezers, and pulled out a leaf here and there, and exchanged another until you would scarcely have known me. Florists, you know, have laid down rules for our growth, and have actually drawn figures of what we ought to be! Hush! here are the squire and all the family this way again; how soon they tire of their parterre! Mr. Cuttings has it all to himself.

ROSE.—Yes, old friend, they'll soon replace us, if I mistake not. Hush! let's hear what they say.—T. W., *Harrow.*

LARGE CAMELLIAS AND ORANGE TREES.

It may interest some of your readers to know that the finest collection of Orange trees, and of large Camellias in Europe, is to be sold this week, and so large is it, that the sale will probably continue until Saturday. They are the property of M. Henri Courtois, who is giving up his business, in the Rue de la Muette, near Père-la-Chaise. The Camellias are some of them sixty years old, and are mostly planted out in a large greenhouse, and look in vigorous health. The sorts, of course, are old. The Orange trees are some of them very fine, and are all in tubs. Their selling price now varying from 200*l.* (£8) a-piece down to 30*l.*, and although the dust of Paris has not improved them, yet they are in fine health, and I have no doubt with more care would soon make noble trees. The constant increase of Paris, and the demolitions consequent upon it, are by degrees driving the nurserymen away. We believe one—the main reason—for the collection being parted with, is the injury that is done to plants by the rapidly increasing buildings round them.—D., *Deal.*

GRAFTING THE WILD OLIVE ON THE OLIVE.

REFERRING to Romans xi. 17, the wild Olive tree being grafted in and partaking of "the root and fatness of the Olive tree," or parent stock, I have heard it stated that in this respect the Olive differs from plants we usually graft; but cannot find any allusion to the alleged peculiarity. Can you give any information on the subject?—S. D. GOFF, *Horetown House.*

[The words of St. Paul as rendered in our translation are, "Some of the branches be broken off, and thou, being a wild Olive tree, wert grafted in among them, and with them partakest of the root and fatness of the Olive tree." This is explained two ways, either of which seems satisfactory. Schleusner, quoting from older writers, renders *agratelaios*, the Greek original, "unfruitful Olive tree," instead of "wild Olive tree," and then it is like many other unproductive fruit trees which are brought into bearing by grafting scions from them on other stocks.

The other explanation is that *agratelaios* is the Oleaster or *Elaeagnus*; and Schulz, in "Paulus's Collection of Travels," states that branches of it are grafted into Olive trees that are barren though cultivated, in order that fruitfulness may be pro-

cured. Theophrastus, Pliny, Columella, and Palladius all mention this fact, but it will be sufficient to quote the two last-named. Columella says—"It often happens although the trees are vigorous that they produce no fruit. Let these be bored with a Gallio augre, and a green graft, or slip, of a wild Olive tree be put into the hole; thus the tree becomes more fertile."—(De Re Rustica, l. 5, c. ix.). Palladius, in his poem on "Grafting," l. 53-4, says, "The wild Olive renders fruitful the barren Olive, and teaches that to bear which knew not how."

But our translation, taken literally, has no obscurity; for it only alludes to the fact that the Gentiles were now admitted to all the privileges previously confined to the Jews, just as the scion of a wild Olive would partake of the sap (fatness) supplied by the root of the cultivated Olive if grafted upon it.]

THE BIRMINGHAM ROSE SHOW FOR 1863.

We last week drew attention to the fact that the prize list for the next Show is now ready, and may be had on application to the Secretary. We have since carefully examined the prize list, and have much pleasure in submitting to our readers a summary of its contents.

As was the case last year, there are three classes. Class A is for Nurserymen. Nos. 1, 2, and 3 (for 96 varieties, singles; 48 varieties and 24 varieties, trebles, respectively), are open to the United Kingdom. No. 4 (24 varieties, singles), is open to nurserymen resident in the counties of Warwick, Worcester, or Stafford only.

Class B is for Amateurs. Nos. 5, 6, 7, and 8 (48, 24, 18, and 12 varieties, singles, respectively), are open to the United Kingdom. Nos. 9 and 10 (12 and 6 varieties, singles), are open only to amateurs resident within fifteen miles of Stephenson Place, Birmingham; and No. 11 (6 varieties, single), is open only to amateurs resident within three miles of Stephenson Place, Birmingham.

Class C is entirely open. It consists of five divisions. No. 12 is for a collection of not exceeding 24 new Roses of 1860-61-62, single trusses; No. 13 for the best new Rose, 1860-61-62, six trusses; No. 14, best six varieties, Roses, single trusses, with stem and foliage as cut from the tree; each truss to be shown singly in a vase to be supplied by the exhibitor. No. 15 is for the best design, basket or vase, of Roses and Rose foliage; and No. 16 for the best bouquet for the hand, entirely of Roses and Rose foliage. It is added as a note to No. 16, that it is essential for the bouquets sent to be suitable for the hand—a much-needed regulation, for usually the bouquets sent are large enough to make half a dozen hand-bouquets of the proper size.

It will be seen that some considerable changes have been made in the prize list as compared with the one issued for the Exhibition held last year; and we are inclined to think that the changes will be also found improvements. The Committee were evidently guided by principle in framing their bill of fare for the year, and we are of opinion that experience will prove that they have been guided by correct principle. While making the prize list in its main features thoroughly unrestricted, so as to induce exhibitors from all parts of the kingdom to join in the competition, some very sensible reservations have been made. These are to encourage local exhibitors to do their best, not but that as far as we can judge, all circumstances considered, the midland counties succeeded in maintaining a very honourable position, even when in hand-to-hand fight with such successful veterans as Turner, Paul & Son, Cant, Francis, and Keynes, who were all prizetakers at last year's Show. We find there were at that Show exhibitors from thirteen counties—viz., Berks, Bucks, Essex, Gloucester, Hereford, Hertford, Leicester, Monmouth, Nottingham, Oxford, Somerset, Warwick, and Wilts. Including extras thirty-three prizes were awarded, and they went in the following proportions to the various counties named below:—Berks, 1 prize; Bucks, 5; Essex, 3; Hereford, 1; Hertford, 5; Leicester, 1; Monmouth, 2; Nottingham, 3; and Warwick, 9. At the same time the limitations of Nos. 4, 9, 10, and 11, will bring out many small growers; and the proper cultivation of Roses in suburban gardens—one of the objects which induced the establishment of the Show—will receive a desirable amount of stimulation.

The endeavour to get exhibitions of Roses grown within three miles of the centre of Birmingham will, we hope, prove very successful. That there are many residents in the immediate suburbs of that and other large towns who are true

subjects of the queen of flowers is undoubted; but that there are at present many successful growers of Roses within three miles of the centre of any town so large and smoky as Birmingham, is, we fear, not very probable; but if the competition in this division should be limited it will not long continue so. The Committee of the Rose Show having offered prizes for a small number of varieties grown within a short radius of the central railway station will naturally increase the number of growers, and the names of the varieties shown in the winning-stands will be read with interest by all small cultivators residing near large towns, as the names of those kinds which they may successfully grow in such unfavourable localities. We would draw particular attention to division No. 14 in the Open Class, as one which we hope to see well filled: it is for the best six varieties of Roses, single trusses, with stem and foliage as cut from the tree, each truss to be shown singly in a vase. Last year the six trusses were shown together as a bouquet; but the plan for the present year will, we think, be found a great improvement on that, besides adding several features of interest to the Exhibition. The regulations seem to be much the same as last year, only such slight alterations having been made as the experience gained by the first Show has suggested. The amount of prizes offered is £106 5s., an increase of more than £20 on the amount paid last year; and in all cases there are to be first, second, and third prizes—liberality which we hope will meet with a hearty response from all the leading cultivators.

CHINESE FRUIT-GARDENING.

MR. FORTUNE, in his pleasant book "Yedo and Peking," mentions, page 321, the Chinese method of cultivating fruit trees in pots which he observed in the nurseries near Tien-tsin:—

"Pears are perhaps the most abundant amongst all the autumnal fruits in Peking. They are exposed for sale in every direction—in shops, in stalls, on the pavement as well as in the basket of the hawker. They were of two or three kinds, and one of them was high-flavoured and melting. This is the first instance of a Pear of this kind having been found in China, and it is a most welcome addition to the tables of the foreign residents in Peking. Curiously enough this fruit, excellent though it is, is as yet unknown at Tien-tsin, a place only about seventy miles distant."

"Apples, Pears, and Siberian crabs are cultivated in pots in these gardens, and apparently with great success, for the little trees were all loaded with fruit. The Chinese have, probably, been doing this for ages past, just as they have been growing Roses in pots, dwarf and covered with bloom, while we have only found out very recently that such things could be done."

It is really true that we have only recently "found out" that such things can be done, and it is not to be wondered at that English gardeners, like English agriculturists when threshing machines were first introduced, should feel that "such things" are innovations, and to be opposed accordingly. Mr. Fortune also describes standard Chrysanthemums grafted on a species of *Artemisia*. Unfortunately, he has omitted to give the species, or to say if he has introduced it. We have, as far as my knowledge goes, no hardy shrubby *Artemisia* fit for a standard stock for Chrysanthemums.—YEDO.

THE TOAD.

YOUR correspondent, Mr. W. Earley, asks, "Does the toad habitually consume worms?" I have two toads, one in each of my Cucumber-frames, which I placed there for the purpose of destroying woodlice, &c.; and now that the woodlice are reduced to "few and far between," I, as a rule, feed the toads four or five times a-week with live worms. I merely place the worms on the ground before them, when, as soon as the worms move, the toads quickly devour them, but never till they move; nor do they touch any kind of food till it moves.—THOS. AUSTEN, *Askford*.

NATURAL HISTORY.

A BALDCOOT was seen with eight young ones on the 23rd April.

WILD Pheasants were seen with young ones on the 5th of May.

CALCEOLARIA TETRAGONA.

POSSESSING considerable beauty in itself, this shrubby species of Slipperwort may effect that improvement in the worn-out garden Calceolarias which the Cape species of Pelargonium brought about in the case of the enfeebled florists' breed of this latter popular flower. If its properties can at all be brought to bear upon the domesticated Slipperwort, we may yet hope to see

some of their acquired beauty of flower united with a vigorous constitution and good habit of growth. *Fig. 1.*

The species was introduced from Peru by Messrs. Veitch, of Exeter. It forms a true shrub with a compact and dwarf branching habit of growth, and bears oblong-ovate blunt entire leaves. The flowers, which form loose corymbs at the ends of the stems,

are large, with a pale-green calyx, and the lower lip of the corolla forms a broad squarish pouch of a pale yellow colour.

The habit of this Slipperwort being all that can be desired in an ornamental plant, and being accompanied by clean-looking, ample, shining foliage, and numerous showy flowers, the form of which, though not exactly agreeing with the artificial "cherry-bob" standard, is not at all inelegant, it is to be hoped that

some persevering hybridisers will by its aid, revivify the Calceolaria as a garden flower.

Like the other shrubby species of Slipperwort, the present may be increased readily by means of cuttings of the young shoots; and the plants will grow freely in a mixture of equal parts of turfy loam, peat, and leaf mould. It, of course, requires greenhouse protection.—M.—(*Garden Companion*.)

DEATH OF MR VEITCH, OF EXETER.

It is our mournful duty to record the death of Mr. James Veitch, of Exeter, which took place on the forenoon of Thursday last, the 14th inst.

Only a week previously Mr. Veitch sustained the loss of his wife, who was buried on Thursday last; and it was on the day of her funeral that Mr. Veitch, overwhelmed with grief for one

he loved so much, was seized with spasms of the heart, and after two hours' suffering, expired in the arms of his eldest son, Mr. James Veitch, of Chelsea.

The father of Mr. Veitch was a native of Jedburgh, in Scotland. At the end of the last century he came to Devonshire, where he ultimately established a nursery at Killerton, near

Exeter, and there the subject of this notice was born on the 25th of January, 1792. So great was the success that attended the formation of this nursery that, in course of time, Mr. James Veitch, finding the distance too great from Exeter, and desiring to be nearer that city, purchased a large extent of ground on the Topsham Road, known as Mount Radford, and there were formed those beautiful nurseries which are now so closely identified with the botany and horticulture of the nineteenth century.

It is almost unnecessary for us to enter into any particulars about this and the kindred establishment at Chelsea, which is presided over by his eldest son, Mr. James Veitch. Our readers and the public are too well aware of the extent and importance of both to require any special notice on this occasion. Suffice it to say that Mr. Veitch has left behind him a name which will rank high in the annals of horticulture.

GEOMETRICAL FLOWER GARDEN.

THE situation of the design is on a small grass plot at the back of my house, two-thirds surrounded by a low rockery, the remainder by a belt of Rhododendrons and Azaleas, and the dining-room window looks down upon it. Ornamental Minton tiles are used as an edging for the beds; and the walks, 18 inches in width, are covered with fine white spar. On making the

design, I had originally intended to use coloured gravels instead of beds; but I changed my mind, and it has been filled with spring-flowering bulbs, and the effect has been generally admired.

Which of the following plans of planting do you prefer?—AN INQUIRER.

PLAN No. 1.

- 1 and 13. Snowflake Verbena.
- 2 and 12. Purple King Verbena.
- 5 and 9. Defiance Verbena. [nium.
- 3. Scarlet Horseshoe Gera-
- 11. Tom Thumb Geranium.
- 10. Calceolaria Aurea flori-
- bunda.

- 4. Ditto Prince of Orange.
- 6. Bijou Geranium.
- 8. Golden Chain or Cloth of
- Gold Geranium.
- 7. Prince Albert Petunia,
- with white Petunia in
- centre.

PLAN No 2.

- 1 and 13. Same as last.
- 2 and 12. Ditto ditto.
- 5 and 9. Ditto ditto.
- 3. Ditto ditto.
- 11. Ditto ditto.
- 10. Ditto ditto.
- 4. Ditto ditto.

- 6. (Christine) pink Gera-
- nium.
- 8. Prince Albert Petunia.
- 7. Centre with plants of Cine-
- raria maritima, points
- with Crystal Palace
- dwarf crimson Nastur-
- tium.

[If you adopt either of your modes of planting, we do not think anybody would find fault with you; but we suppose you will not owe us any thanks if we do not propose an amendment. Well, then, considering that your walks are a white spar, we think there is rather too much white in the beds, and it will be mostly in a line from the house, as 13, 7, 1. Now, we like your idea of 7 shutting out the white by pink from the walk, but we do not think that Petunias will suit you with their rambling propensities in such a garden. Our first suggestion then is, that the centre of 7 should be white Verbena, and the corners of the star of such a puce or purple, as Charwoodi and Christine Verbenas, &c. Then we would centre 1 and 13 with Cloth of

Gold and Golden Chain Geranium respectively, with a band of Lobelia speciosa—that is to say, if we did not make the whole beds of Lobelia. Then 8 and 6 we would fill with Bijou, with a border of Christine, and the rest as stated, or 8 and 6 might be Christine, with border of Elegans Crystal Palace Nasturtium. We would prefer the first, as the fine green leaf of Christine will come in well with the spar, and the centre of the beds being white, green, and scarlet, will light up that part well. We do not say that our plan is better than your own, but we think it would be an improvement; and however planted we should like much to see it, as if the beds are well managed the picture will be a pleasing one.—R. F.]

THE BEST BOILER FOR HEATING HORTICULTURAL STRUCTURES.

FOR several years past I have had the care and management of sundry kinds of boilers, and I have no hesitation in saying that the upright tubular boilers are the most powerful and effective. It is a well-known fact that hot water will flow much faster in a vertical tube than in one laid horizontally; and although this is the case, most of the upright tubular boilers have horizontal firebars, and only one communication between them and the boiler. I think this plan defective. I think there ought to be as many communications as possible, and this should be direct; for I am quite certain there is in a red hot furnace a most intense heat upon the tubes over the fire, and the faster the water can circulate out of them the better.

Twelve months ago last March my employer had the vineries and conservatory refitted with new boiler and piping. All the Vines were taken out of one house and replanted. Mr. T. C. Clarke supplied the heating apparatus and piping. It was suggested to have a £20 saddle boiler, but as Mr. Clarke stated that his No. 1 boiler would be sufficient, the cost of which would only be ten guineas, I thought we could not do better than have it; but certainly, when I saw it being put in, I feared it would be scarcely large enough to heat one house instead of four. We have three vineries about 65 feet long by 16 wide, and seven rows of pipes in each house; then we have a conservatory to which the mains from the boiler are connected, about 30 feet from the vineries, which is about 55 feet long. I suppose altogether there will be from 600 to 700 feet of piping, and I feel certain, if it was required, in the course of an hour I could get the water to nearly a boiling heat throughout all the pipes.

I have now had this boiler at work better than twelve months, and I have no hesitation in saying that it is the easiest boiler to manage I ever had to do with. The two great improvements effected in the construction of this boiler are the water-jacket furnace, which is of great strength, and a simple ingenious invention, placed over the top of the boiler to keep in the heat. This is effected by means of two slides fitted on each side of the plate, called the deflecting flue-plate, which can be opened or shut at pleasure. When closed the heat is kept in close contact with the boiler. In most of the other constructions I have had to do with the damper has been placed some distance from the boiler; consequently, much of the heat passes into the flue, whereas, if it were cut off close to the boiler, it would be kept at the boiler.

I also consider this boiler the most economical one I ever had. A gentleman stated the other day, who has one the same size as mine, that he had a range of houses, about 70 feet in length by 15 wide, consisting of a stove, one vinery, and two greenhouses, that two tons of common gas coke had lasted him since Christmas. This at 6s. 8d. per ton would only be 13s. 4d. for the whole winter. Common gas coke suits these boilers best; but they will almost burn anything.

There is another excellence in these boilers—they never get choked up with soot. There are two small soot-doors in front for cleaning the flues out occasionally; but they do not require it more than once in two or three months. I should recommend No. 2 boiler for this reason—it holds more fuel than No. 1. It has been lately fixed up in this neighbourhood, and is heating 1200 feet. Mr. Perring, the head gardener, states that it does its work very satisfactorily; and I believe he is a good judge. He is one of the oldest members in the Horticultural Society, and one of the growers of the finest Grapes in the country.—*R. CARMYLE, Gardener to J. Robinson, Esq., Toxteth Park, Liverpool.*

THE DISEASES OF THE LARCH.

PRIZE ESSAY, BY JOHN MORRISON, CONEY PARK NURSERY, STIRLING, IN THE "TRANSACTIONS OF THE HIGHLAND AND AGRICULTURAL SOCIETY OF SCOTLAND."

THE failure of the Larch in this country cannot but be viewed as a serious matter, and deserves the attention of all who are in any way interested in growing the tree or using the timber. Larch has become almost indispensable for certain purposes, and we have no proper substitute for it. Its rapidity of growth, and the durability of its timber, gave it considerable commercial importance, and any curtailment of the necessary supply would not only be generally felt to be a great inconvenience, but, in a

money point of view, a heavy loss. It was supposed by some that the Deodar (*Cedrus deodara*), would in a few years become the rival of the Larch, the Deodar being also of quick growth, and its wood of excellent quality; but the effects of 1860-1 winter's severe frost upon this plant will be an obstacle to its introduction into the market for many years to come. In these circumstances, I consider it to be the duty of every person having a practical knowledge of the habits of the Larch, or who has watched the progress of the disease from its first appearance in the young plants, to state his views for the information of those men immediately concerned in the cultivation of the tree. And I beg respectfully to submit the following statement as the result of actual experience and observation, not being aware that any one has taken the same view of the case while treating of this subject.

In reference to the soil most suitable for the growth of the Larch, there is considerable difference of opinion. Although a good medium loam with a dry bottom is that best fitted to bring the timber to perfection, yet for the first twenty or thirty years the trees appear to thrive equally well on strong loam or poor gravelly land. After attaining that age, the result appears to tell more in favour of the loam; and I believe the finest specimens of the Larch in the north of Scotland are to be found growing on the edge of a moss or bog. Nevertheless, in almost every variety of soil we hear of the disease lurking.

If we examine the effect of situation in connection with soil, although it is found that in some localities a southern or western exposure is most agreeable, in other places the trees do well in an eastern or northern situation; so that there seems good reason for believing that soil and situation have comparatively little, if indeed anything, to do with the prevalent failure of the Larch.

To what, then, is the disease attributable? In tracing the history of the Larch from its introduction into this country in the beginning of last century, we may safely conclude that as much care and attention would be bestowed on its cultivation as is now given to that of our more recent and expensive introductions of the Conifers, and under such management no symptoms of decay appear to have manifested themselves; but when the quality of the timber became known and appreciated, immediately greater breadths of land were planted, and in very many cases, I am afraid, without suitable preparation or care, either as regards proper selection of seed, draining, or thinning; and to this heedless system of cultivation there can be no doubt the commencement of the disease belongs.

The Larch thrives on the mountains of the Tyrol, &c., at an elevation of from 3000 to 6000 feet above the level of the sea, and, therefore, it may well be considered sufficiently hardy and suitable for our climate. Although growing in such a high region, the trees mature their seeds much better than in this country; and admitting that all seeds from the Continent are not got from such elevations, yet throughout they have a warmer and longer summer, while the variable character of our summer and autumn weather does not permit their perfect development. Imported seed is more firm and plump, and generally grows two to one as compared with home-saved. We cannot expect a strong healthy plant from a half-filled half-ripened seed. Although such may germinate, it can only produce a sickly tree, and this in turn brings forth its kind. We know well that a Larch in an unhealthy state produces double the quantity of cones that a vigorous tree does, and therefore it becomes a most important question, Do the seed-collectors reject this unsound seed, or do they gather indiscriminately? Being in conversation a short time ago with a well-known Scotch Fir and Larch seed-collector in the north of Scotland, I inquired whether it was the general practice for dealers to gather seed from trees which were evidently in an unhealthy condition. He stated that such might be the case on the part of some seed-collectors, but his own invariable rule was to take seed only from mature and vigorous plantations; and he had no doubt whatever that what was gathered from weakly trees produced none but feeble and diseased plants. This statement confirms my own previous conviction, and coming from a gentleman of extensive experience, shows that the disease is largely propagated by inferior seed; and until a system of selection obtains, and collectors superintend personally the gathering of their seed, in place of buying the cones at so much per bushel or peck, we can never hope to eradicate the evil and regenerate the stock.

I have no hesitation in saying that but for a few of our nurserymen, who have been in the habit of importing a quantity of foreign seed annually, and by such means infusing, as it were,

fresh blood into the source of supply, this troublesome disease might have been much more general and serious than it is. We frequently hear of some plantations growing strong and vigorously, while others, in precisely the same circumstances, prove complete failures. The cause is to be found in the seed being good in the one case and bad in the other. I have always found that where the genuine Tyrolean seed, or that from high localities, is grown, the plants surpass in healthiness and rapidity of growth those raised from home-saved seed; and while it has been objected that such plants are less hardy than those raised from our own seed, I can state that, for a long time past, I have carefully watched the progress of both, side by side, from the one-year seedling to the two-year transplanted, and after the first year could never perceive any difference between them. In some seasons I found the one-year foreign seedling prolonged its growth in autumn, and was apt to be caught by early frost; but, after being transplanted, I have never observed any dissimilarity in regard to early or late growth.

In addition to what I have thus indicated for the prevention of the disease and the improvement of the stock, I would further suggest that a somewhat different management is requisite on the part of nurserymen. In place of having beds $3\frac{1}{2}$ feet broad, and from 20 to 25 yards long, producing 40,000 to 50,000 one and two years seedlings, were the same space of ground to contain about half the above quantity, it would conduce greatly to the healthiness of the trees. The best soil is productive only to a certain extent, and beyond that limit nature will not by any means be forced. No tree is more sensitive of confined space and impatient of want of air than the Larch; and while in some cases a short-sighted and mistaken policy may still compel adherence to the present practice of crowding, I am thoroughly convinced that true economy consists in growing the plants much thinner than has been generally done. Even with an additional cost of about a third more per 1000, superior plants would ultimately be found much cheaper than those now to be obtained in the market, and there can be no doubt they would come to be preferred.

A thorough system of draining for forest-planting is also needful, for the Larch does not thrive in wet, sour land. Every piece of ground allotted for this purpose should be carefully examined, in order to ascertain what extent of draining may be really required; and although the roots of trees seldom go far into the subsoil, it is generally advisable to drain to that depth; and after the drains are made, should the land be very wet, it would be much better to wait for a season until it drips sufficiently. Experience has proved that, without attention to draining, any previous care bestowed in the selection of proper seed, or in the preparation of the land, is utterly lost; and proprietors would consult their own interest by cordially seconding the exertions of their foresters in this important matter.

Besides the suitable preparation of the soil, there is yet a most essential part of forest-culture to be attended to—viz., the early and careful thinning of the young plantations. Whether it be the case that the blistering which frequently manifests itself on naked and drawn trees in plantations is the result of raising from thickly-sown seed, I am not prepared confidently to assert; but it is possible that such may be the fact, and that the germ of the disease may remain latent in the plants till they arrive at a certain age. The existence or development of this excrecence greatly depends on the future circumstances of the young trees; and nothing encourages this unhealthy token so much as having them growing close together. In such a condition, having no room to expand, they become lank and bare, and on being thinned are all the more liable to be caught by the spring or autumn frosts at the ascending and descending of the sap. Suffered to grow deprived of the needful circulation of the air, they acquire a sickly habit, and when suddenly exposed, the change is too much for them; they are, as it were, frost-bitten, and the blistering is the manifestation of the evil. But careful and timely attention to the requirements of the young trees would prevent this. Were a sufficient space for their healthy development always maintained, and the clearing-away of all superabundant growths attended to, it would allow the plantations to get a fair start; and I have no doubt the young trees would soon acquire a vigour such as would enable them to overcome any tendency to blistering which they might otherwise exhibit. We seldom see a Larch covered with branches to the ground presenting a blistered appearance; and were the treatment here suggested generally followed out, there would be comparatively few cases of failure heard of.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE Broccoli season being now nearly over, the stumps should be all cleared away, and the ground dug; or, if intended for Celery-trenches, these may be prepared without digging the whole of the ground. *Beans (Broad)*, as soon as the pods begin to form at the lower part of the stem, top the plants, which will greatly forward the cropping of them. Earth-up the successional crops after a shower of rain. *Brussels Sprouts*, prick-out the early sowing to strengthen them previous to finally planting them out. *Carrots*, sow Early Horn to draw young during the summer. *Celery*, prepare trenches by throwing out the soil from 1 foot to 18 inches deep; and for the early crop, which is seldom allowed to stand till it attains full size, $2\frac{1}{2}$ feet between the trenches will be sufficient. Dig into the trenches 6 inches of old hotbed dung, which for Celery is preferable to that which is rank and new, and as soon as the plants are ready plant them carefully, choosing a dull day for the operation, make a hole for the ball with a garden trowel, and finish with a good watering, and where practicable shade for a time in bright weather until they get established. *Dwarf Kidney Beans*, sow for succession, and transplant those which have been forwarded if not already done. *Parsley*, thin out the plants of the early sowing to 6 inches apart. More seed may now be sown. *Peas*, continue to earth-up and stick the successional crops. Sow, also, in smaller quantities for succession. The north sides of sloping banks are well adapted for these sowings, being cooler and more retentive of moisture. *Radishes*, sow the Long Scarlet, and generally Turnip sorts. *Scotch Kale*, sow; as also the old English Colewort. Both are very useful for planting after Potatoes. *Sea-kale*, remove the pots and also the covering as soon as done with, and afterwards dig between the plants. *Spinach*, thin the early crops, and sow again for succession. Prick-out all sorts of advancing seedlings that they may be stocky, and gain strength before their final planting. Stir the surface of the soil wherever the late rains have hardened it. Above all things catch the slugs, which are very numerous this season. Sprinkle crops they are fond of attacking with soot and lime mixed, and lay traps for these—such as cabbage leaves, slates, pieces of board, &c., and turn these over daily, when numbers will be found on the side that has been next to the ground and can be destroyed.

FLOWER GARDEN.

As the shrubbery will soon present a gay appearance, activity and attention must be the order of the day in this quarter, that the deciduous and evergreen flowering-shrubs may appear to the best advantage. Nettles, Thistles, and Brambles should never be permitted to make their appearance here. There are plenty of these to be seen in every hedgerow. The *Paeonies*, *Philoxes*, *Delphiniums*, *Lysimachias*, and other tall herbaceous plants to be properly staked. Roll, mow, and clip the edgings of grass lawns once every ten days, and use the daisy-rake at intervals. Thin out annuals, stake plants in the border as they grow, remove all decayed leaves and flower-stems, and everything disagreeable to the eye. What delightful weather we have had during the past week! It has been all that could be desired for present operations. *Verbenas* and *Petunias* should now be turned out into their summer quarters. Peg down all the shoots when the planting of the border is finished, and before another bed is commenced. Plant out Dahlias that have been grown in pots into the flower-borders, fill up the holes with some good compost and finish with staking each plant and mulching the ground. The early-flowering bulbs—as *Tulips*, *Hyacinths*, *Turban Ranunculuses*, &c., should not be left in the ground after the decay of the foliage, as if wet weather occur they will be making fresh roots, which weaken them for next season. Roses will require frequent examination. Remove unnecessary shoots at once. Plant out in rich soil a good supply of *Stocks* and *Asters* for the autumn, and sow a succession of annuals for making up any vacancies that may occur; and likewise make another sowing of *Mignonette* in pots, for the rooms or for filling window-boxes.

FRUIT GARDEN.

Peach and Nectarine trees infested with green fly or curled or blistered leaves to be well syringed with strong lime water in a clear state from a syringe or garden engine. Continue to nail young shoots of all kinds of fruit trees as they become sufficiently advanced. Give the Strawberry-beds a final stirring, and have some available material at hand for laying about them to

prevent the fruit from getting dirty. Straight wheat straw is often used in preference to clean short grass.

GREENHOUSE AND CONSERVATORY.

One great object in plant-houses at present is the preservation of the blossom from the burning effect of the sun. Abundance of air and moisture, proportioned to the demands of the plants, with shade, must be provided. Camellias, during the formation of young wood when they should be kept damp and warm, are too often packed together out of the way; at no time do they require more room and attention. The Chinese Azaleas which have been some time growing should be kept in heat until they have set their buds, when they may be removed to the open air; as may the Oranges and Camellias when the shoots get firm; exposure afterwards, if protected from heavy rains, will assist them to ripen their wood. Examine Heaths frequently for mildew, and apply sulphur the moment it is perceived, some of the soft-leaved varieties being very liable to be attacked by that pest at this season.

STOVE.

As regards stove plants and Orchids, thorough cleanliness, free ventilation, plenty of atmospheric moisture, and occasionally a slight shading in very bright sunshine are at present the chief requisites. No means should be neglected to encourage a free growth at this period in Orchids, in order to have their pseudobulbs firm and well ripened betimes.

PITS AND FRAMES.

Young stock in these structures will now be making rapid growth, and must be carefully attended to as to watering, stopping, training, &c. Expose Zinnias and other tender annuals entirely night and day by removing the lights and covers. Plants that are being kept to succeed Tulips, Ranunculuses, &c., next month to have plenty of room given to them; the lately-struck plants require attention, they will come in very useful by-and-by to fill-up vacancies in beds, &c.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

FINE gentle rains have come at last, enough to make the hard clods crumble nicely, but not enough yet to do much more than damp the parched surface. Sowed Peas, Beans, Kidney Beans, and Runners, damping the drills well after sowing before covering up. Gave Cabbage and Cauliflower that we wished to cut early, good soakings of manure water. Watered Turnips, and transplanted a few, though the garden sorts do not answer so well as the Swedes. With the latter there is no difficulty, and were we farming we would always have a nice little bed in the garden for filling any vacancies in the field. In fact, could we make sure of dripping weather, it would be the cheapest of all plans with Swedes, as we could keep them in a bed easily cared for, and protected from fly, and plant after all danger was over. The only secret is firm but shallow planting, just as in the case of Onion-planting. The great point with the latter is just to fix the roots, and not bury the necks, for if you do you will have thick necks and poor bulbs: hence, as a general rule, autumn-sown Onions make the best bulbs, when carefully transplanted. We have effected the same object by moving the earth from the necks of those left standing before they began to swell much—say in March. Carrots and Parsnips may also be transplanted in an emergency, but they do not in general do so well as when left where sown. Beet, on the other hand, transplants well, especially when young.

Pricked out Cauliflowers and Lettuces from seed-bed, and sowed more, also the general stock of Coleworts, and a few more of Broccoliis, though thinking we had pretty well enough for our wants. Threw a little lime and ashes among the seed-beds, to keep slugs off, and make them more stubby, and less inclined to get leggy and foxy. Run the Dutch hoe through Onions, Carrots, Parsnips, &c., and sowed succession of Carrots, the main crop of Beet, Salsafy, and Scorzonera, and also the last of our Sea-kale and Asparagus seed, having failed to find a piece of ground for it before, and the first sown six weeks ago, owing to the dry weather, is not yet up, though all safe and swelling in the ground. It is a good plan to sow *Asparagus* in the autumn as soon as the seed is gathered. Cut off the strong seed-stems of Sea-kale, and thinned redundant shoots. If these are planted with a bit of the old stem in dripping weather, they will make good plants before the autumn. A little salt, just enough to whiten the ground slightly, two or

three times in summer, will do them much good (and the same may be said of *Asparagus*), and manure water, too, at that time, though we have little faith in either salt or manure water being applied when the plants are at rest in winter. The salt, also, helps to keep down weeds. Attended to *Cucumbers* bearing just too freely; thinned out fruit, and stopped and regulated, as, if bearing too much in April and May, the plants are sure to be prematurely exhausted. Potted off those for ridge, Gherkins, and Vegetable Marrow, as the place is rather cold for these things to do much good when sown in the open air. In fact, we find that they are all the better of a little bottom heat to start them in. About Sandy and Biggleswade they have no more trouble with *Cucumbers* for the autumn supply than other folk have with Peas, except the thinning of the plants, the seeds of which are sown in rows some 5 feet apart. In common circumstances, however, north of London, the plants will do better with a little hot litter and short grass placed beneath the soil, and it matters little how it is done—whether placed in a trench, or in a hole with the soil above; or a ridge should be made on purpose, with earth thrown over it. Large Gourds are also helped by this process, though they will often attain 100 lbs. weight if planted in rich soil, and well supplied with manure water.

After having tried Custard and other Marrows, we have fallen back on the old Vegetable Marrow, just because good judges say that after all it is the most desirable for cooking purposes. We cannot say much on the subject, as such a dish once a-year is as much as we have ever ventured upon. As our Mushroom-bed in the shed was just perceptibly warm, added 1½ inch of droppings, beat firm, and earthed over with about 2 inches of soil, the lower part fresh lumpy turf, and the upper fine riddled loam beaten firm, watered and beaten again, so as to make it about 1½ inch thick. We expect this bed will bear soon, and we must put up a bit more without delay. The Covent Garden people know the luxury of a thick, moist Mushroom in June, July, and August. A cool cellar in these months might be better than our thatched shed, though the latter answers remarkably well. Pricked out Celery, and defended from the sun, and watered freely the first plants, which will soon be turned out.

FRUIT GARDEN.

Disbudded, hunted for insects, thinned Grapes, watered Vines, watered Figs, thinned Peaches, tied shoots as we could get at them, and kept earliest pit of Vines drier, as the Sweetwaters are changing fast. Regulated *Melons*; set these in flower, leaving air on night and day, though the air should be only a quarter of an inch, by means of a peg at top and bottom of the sash in cold nights. The draught of air is of great assistance in insuring an abundant setting, and a little air at all times at the top is a great preservative against canker, damping-off, bad setting, and blotched and scorched leaves. Our earliest this season will be in common frames, and the heat beneath them is formed chiefly by mowings of the lawn, leaves, and a little dung; the layer of old leaves being at the top. When well mixed such a combination will maintain heat long, and may be used safely; but if the precautions insisted on often are not attended to, failure from steam and noxious vapours will be the result. Many use such materials as "W. M." proposed doing at page 351, and ruin is the consequence. We were lately told of some fine new *Geraniums* that it was advisable to hurry on that were thus ruined in a night. We have known scores of instances in which *Melons* and *Cucumbers* in frames were injured and ruined by allowing the steam from a fresh lining to get inside of the frame, and no method will insure this more effectually than sliding a sash down over a fresh-made lining in front. So much easier is it to slide a sash down than to tilt it up at the back, that eight out of ten men will slide the sash instead of elevating it. Not only is there this additional danger in such circumstances from steams and vapours at an early season, but the cold air strikes the plant at the back before it is so much warmed as it would be when, by elevating the sash, the cold air is mollified by passing through the heated air as it rushes out. It is a good plan to have ventilating-boards for this purpose tied by a string to the back of the frame, either cut in a triangular form, or, what is better, with notches cut into them, so as to hold more securely; for if not tied they will always be to seek when wanted. We dwell on these little matters the more, because want of attention to them is often fatal to the plants and the crops. In every case of new lining, the inside of the frame should be examined, and the ground made firm all round the box, so that steams shall not enter. If the bed is made 2 feet larger than the frame every

way linings will be little needed, and the manure may be banked up against the frame, and thus throw in atmospheric heat, which will permit of more air being given, and secure the roots more from excessive heat than when all the extra heat of the confined atmosphere has to rise through the soil in which the plants grow. See mode of making such beds page 349. We must find a place for potting young Vines as soon as possible.

Several friends on whose opinion we place great value, have expressed their conviction that early Grapes from Vines in pots, though looking as well, are not so rich in flavour, and are more watery than those planted out. We think we have sometimes noticed the same thing, and we throw it out for consideration, as the place that grows Vines in pots would often grow them quite as well planted out, and at a great diminution of labour. One friend attributes the want of consistency and firmness to the delugings of water the plants must receive if kept entirely to the pots.

ORNAMENTAL DEPARTMENT.

Potted Ferns, Achimenes, and a few Gesnera zebrinas, and others, Cannas, Marantas, &c., and placed the fine-leaved Begonias, Gesneras, &c., under Vines, where they will receive the necessary shade; the Cannas, in cool house, to harden them for out-of-door work. Removed Primroses and part of the Cinerarias from conservatory. Set the former in front of orchard-house to ripen a little seed, and the latter out of doors preparatory to planting them out. After June we always think that unless in a cool shaded house, Cinerarias are more trouble than they are worth, as when not kept cool and airy they are apt to be covered with insects. Sowed seeds of Cineraria, will plant good kinds out for suckers. Pricked off *Primula sinensis* from the first sowing. Potted young plants of Pelargoniums and Geraniums, and took those in bloom to the conservatory. Potted Fuchsias, Lantanas, &c., for summer and autumn flowering, and potted and boxed all the Dahlias, and placed them where they would root quickly preparatory to hardening them off. Potted Chrysanthemums, at least a portion of them, which ought to have been done before, if massive plants were desirable. Pricked off lots of annuals of a half-hardy character for the flower garden, as Asters, Marigolds, Stocks, &c., that they might plant better by-and-by. Sowed lots of Mignonette and hardy annuals in the way described the other week. Gave full exposure to those coming up, that had been sown in a bed under a piece of calico, so that they might be moved in patches, as described at pages 321 and 322. Potted-off in small pots lots of Petunias of favourite kinds, as they stood so thick in the cutting-pots, and gave them a little hitch under glass in a mild hotbed. Pricked-off more Lobelias in case they should be wanted, and, as we find our Perillas are rather late and we like to turn out good plants that will look after themselves, have potted and pricked-out a good many hundreds in a mild hotbed; and we must wait eight days or a fortnight before we can plant them out.

This is a step that does not suit my good assistants from the neighbourhood. If there is one thing more than another they dislike when planting, it is the leaving a part of a bed or a border unfinished as they go. Another proceeding which goes against the grain, is the planting a front row higher than a back row. Now, as it so happens that we want a lot of Perillas in rows between the grandiflora double Feverfew, and yellow Calceolarias, and both of these are from 8 to 12 inches in height, we must have the Perilla somewhat passable before placing it between them—say nice plants some 6 to 12 inches in height, and they will be getting to that in a fortnight under good treatment under glass. It is true, we might plant them smaller, but then would not my boys turn up their noses at them, and as much as hint that surely I did not mean it?

In all combinations of colours and arrangements of groups of flowers, the question of heights is of as much importance as that of colours. This may not seem to be the case in some large establishments, where the labour power is so liberally supplied, that a plant naturally 30 inches in height may be pegged and dressed to be only 6 inches high; but these matters are of moment, when pretty well as good a show is expected, and a vast deal more besides, at an outlay little beyond what in the large establishment would be spent in fuel alone.

The refreshing showers having put some water in our tanks, we began to feel more independent. Earth-pits of bedding plants that were covered and protected not so much from cold, as from sun, have been uncovered since then night and day, and have got beautifully watered for planting, and hardened-off at the same time. Some of our Calceolarias have now grown rather

large, but they lift with good balls. If we had potted them, independently of the labour of watering, we could not have given them the water to keep them healthy. The rain also cracking the clods of the hard-baked ground, enabled us to break them with the back of the spade, and turn down the wet surface, and turn up that which was dry, and thus the surface will be warmed and moistened at the same time.

This favourable change has set us planting sooner than we otherwise would have done, and most likely thousands of plants will be in the ground before this is ennobled in printer's ink. We have, however, begun with the hardest first, as Calceolarias, which wanted moving, Scarlet Geraniums, &c. We notice the requirements of a correspondent as to the arranging of colours, the distance of plant from plant in planting, &c. For the arranging of colours there are no such instructions to be gained elsewhere as are to be found in the plans of flower gardens in these pages, the mode of planting, and the good-natured criticism on the systems adopted. A correspondent told us the other day, that in a few Numbers he gained more explicit information on these subjects than he could obtain at the expense of many pounds, from consulting the high-priest professionals of taste.

Could we use the liberty and audacity of our good friend Punch we might hint about the game, and the wine, and the salmon, and even the beef, that are no bad things for the labourer that is worthy of hire. In the meantime we would merely state as to distance in planting that that must depend greatly on the size of the plants and the time the best effect is wanted. For instance: If the beds are wanted to be full soon we must plant thickly, even if we have to thin afterwards, to keep up succession of bloom. If the display is not wanted until August, after the close of the London season, then for free-blooming the planting should be rather thin. As an instance, we have just finished a border 5 feet wide and some 600 feet long that has been panelled, ground coloured, and dotted, and in ever so many modes. It will be seen from both sides. This season there is an edging of Cerastium on each side, a centre line of yellow Calceolarias, and a line on each side of purple-brown Calceolarias between the yellow and the Cerastium. There will be higher plants some 4 feet in height in the row of the yellow Calceolaria at 7 feet apart, and these raised specimens will be purple, crimson, blue, scarlet, &c. The yellow Calceolarias, strong plants, stand 1 foot apart in the row, and the purples, not so strong-growing, are some 8 inches from each other in the row. Of course, while the colours will be somewhat distinct, it is intended that the whole ground shall be covered, and the one row touch the other. We could hardly make the general planting interesting without some rough plans. This season, for various reasons, we will take the simplest modes of planting—that is, what will require least time in planting, and least labour in attending to afterwards; so that we hardly think that minute details would be interesting, especially to those to whom intricacy and augmented care and labour are pleasing considerations.—R. F.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

ROYAL HORTICULTURAL SOCIETY'S FLORAL COMMITTEE.—We are informed by Mr. W. Earley, gardener to Felix Pryor, Esq., Digswell, that he exhibited on the 5th inst. the Tea-scented Rose *Devoniensis*, which we attributed to Mr. Trean.

BOOK ON GREENHOUSE AND HOTHOUSE MANAGEMENT (*H. T.*).—There is no better directory than "IN-DOOR GARDENING," by Keane, which you can have free by post from our office for twenty postage stamps.

VINES WITH WARTED LEAVES (*F. A. Mansfield*).—There is no disease affecting the Vine leaf that we notice, except some excrescences, the result of too much moisture at the roots and a too close moist atmosphere inside. Extra drainage if needed, and especially a drier and more airy atmosphere, are the remedies.

GARDEN ENGINE (*M. W. H.*).—The maker named is Mr. G. Heaven, Hight Street, Birmingham.

FLOWER-GARDEN PLAN (E. W.).—We like your first proposal for a centre best—*Cineraria maritima*, Tom Thum's, and Flower of the Day. 2, 8, will be beautiful, and so will 5, 11. You have partly crossed the other colours, such as 4 and 10 Deference Verbena; and we would carry the principle out with 6, 12, white Verbena; 7, 13, purple Verbena; and 3, 9, might also be a purple or puce, as Christine or Wonderful, or such dark things as Stella Germanum or even two beds of Heliotrope. The two side wings will also do very well; but we would have preferred edging all the beds there or edging none. We think also the plan would be improved by doing away with fig. 18, and bringing 15 more into the centre. We also think that there would be too much of the same colours in 20, 18, and 15. We would prefer 18 to be Frogmore Scarlet edged with Cerastium, which would break the line of orange in 20, 18, and 15. We will have your centre engraved, and then return the drawing.

OLD VINES FAILING (M. B.).—Under the circumstances of building a new viney, and the old vines having failed for three years, we would prefer new vines in a fresh border. Old vines often do remarkably well when carefully lifted. If very old there would be some trouble with them.

ENOTHERAS ACAULIS AND NANA AS BEDDERS (S. M. S.).—*Enothera acaulis* is sometimes good, but in our opinion not much to be depended on for regular flowering. *Enothera Drummondii* nana is a strong-growing trailing plant, with large, fine, yellow flowers, best treated as a half-hardy annual—that is, sown in a little heat and then transplanted, and thus treated it will bloom until frost comes. The flowers are as large as half-crowns. Treated in the same way as a low plant, with bright orange flowers about the size of a large sixpence, and the plant about 9 inches in height, few annuals are more beautiful than *Enothera bistorta* Veitchiana. See article on "Annuals" recently contributed by Mr. Fish.

HEATHS AFTER FLOWERING (Country Curate).—You might have left the plant of *Erica hyemalis* a fortnight in the propagating-house after potting, and you had better place the plant now in a frame or pit, where you can keep it closer—that is, with less air than in a greenhouse, until the shoots are growing freely, when more air can be given by degrees to ripen the young shoots in the autumn. *Hyemalis* stands cutting back more than most heaths; and we see nothing wrong in your treatment if you are all right as to soil, which you call poor, but when in a young state such plants must be chiefly grown in sandy heath soil. As they get well established such kinds may have a little fibry loam. If you have put your plant in loam the sooner you change the soil the better.

GOOSEBERRY SAW-FLY (J. M., Boston Spa).—The insect enclosed is a small bee, and has nothing to do with the Gooseberry caterpillar, which is the larva of a Saw-fly.—J. O. W.

VARIOUS (A Young Gardener).—The *Panercium speciosum* will do best in a mild stove when making its growth, and in a warm greenhouse when in bloom, and when at rest. Give the *Cyanophyllum* a little loam with the peat, allow the heat to fall to 65° or 70° at night, and shade from bright sunshine. The *Dicksonias* and *Alsophias* would most likely be the better, if underpotted, of a larger pot and fresh fibry loam and peat, getting rid of a good portion of the old soil. Keep them a little warmer for a month afterwards, and shaded. They will be the better of weak clear cool manure water such as that from old cowdung.

VINES FOR AN ORCHARD-HOUSE (A Three-years Subscriber).—Two Black Hamburgs, Chasselas Musqué, Early Saumur Frontignan, and two Royal Muscadines.

BEDDING-OUT (H. L.).—We think that in "Doings of the Week," to which you refer, you will find much of the information you require. In a late article on annuals, you would also find something suitable on sowing. As a general rule, with the exception of *Calceolarias*, it is well to strike the most of bedding plants early in autumn. The distance of planting in beds and ribbons has, perhaps, not been sufficiently alluded to, and this matter "R. F." will bear in mind. Meanwhile it may be stated, that blue *LOBELIAS* should not be more than 6 inches apart; *Calceolaria Aerea* floribunda 10 to 12 inches; Tom Thumb *Geranium* 12 inches; *Alma*, *Bijon*, 10 to 12 inches; larger kinds more apart. It is better to thin when too thick, than to have patchy beds.

DISEASED GRAPES (Maria).—Not at all owing to mildew. It is called by gardeners "the spot," and is caused by the roots being not sufficiently active to supply the demands for the upper growth. Removing the soil from above the roots, replacing it by some richer compost, and covering the surface at night and during heavy rain with mulch, and uncovering during sunshine usually removes the malady. If the roots have descended into wet or ungenial subsoil, they must be brought to the surface next autumn.

GREENHOUSE FERNS (Tyro).—Shifting these and *Lycopodiums* into larger pots now will not retard their growth, if care be taken not to disturb their roots. A mixture of cocoa-nut fibre dust, loam, and silver sand in equal proportions will suit them all. By the beginning of June we shall publish a highly illustrated work upon the culture of exotic Ferns, hardy, greenhouse, and stove.

BOOKS (Oatlands).—Our new Manual "Manures for the Many," is in the press. You cannot have a more suitable book than Sanders on "The Vine," which is published at our office, price 5s. You can have it free by post if you send two additional postage stamps.

NAMES OF PLANTS (N. K.).—1, *Veronica gentianoides*; 2, *Corydalis lutea*; 3, *Asphodelus luteus*. (J. D.).—1, *Doronicum pardalianches*; 2, a *Symphitum*; 3, a *Carex*; 4, a *Luzula*: all unfit for examination. (C. C.).—The only one we recognise is *Euphorbia amygdaloides variegata*. The rest are too immature and insufficient. (E. F.).—*Erica carnea*. (*Ameius*).—1, *Hyacinthus non-scriptus*; 2, *Valeriana dioica*; 3, *Galium cruciatum*; 4, *Achillea millefolium*. (H. G.).—Very crushed, seems to be *Begonia Ingrami*. (*A Subscriber, Kilrush*).—1, *Caltha palustris* fl. pl.; 2, *Mathiola tristis*; 3, *Leucocjum aestivum*; 4, *Funkia albo-marginata*. (*A Subscriber, Exeter*).—The variegated *Hydrangea* is a greenhouse plant. Your other plant is apparently *Heterocentrum mexicanum*, and requires stove treatment. (H. N. E.).—Your plant is *Euryops punctatus*, of De Candolle ("Erodromus," vol. vi., p. 445). It is a Cape plant, and its hardness therefore doubtful. You describe it as "a hardy evergreen shrub with very pretty foliage, which makes it useful for winter nosegays." Do you mean that it is really hardy, or merely that it has withstood the late mild winter? If you find it permanently hardy, whereabouts is your residence? We ask these questions because it will be generally interesting to know that this plant is able to endure our climate. (M. J., Adamstown).—It is the American Cowslip, *Dodecatheon Meadia*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY SHOWS.

MAY 25th, 26th, 27th, and 28th. NORTH LONDON (Agricultural Hall, Islington). Sec., Mr. J. Sillitoe, Agricultural Hall. Entries close May 15th.

MAY 28th. NORTH HANTS. Sec., Mr. Henry Downs, Basingstoke. Entries close April 23rd.

SEPTEMBER 2nd. COTTINGHAM. Sec., Mr. J. Brittain.

CHICKENS OUT OF DOORS.

THE advent of refreshing showers will bring gladness into many a poultry-yard. The hard, parched, and cracked earth that starved all animal life on its surface, and imprisoned all that was beneath it—that prevented the chickens from scratching, and that yielded no more food than a deal board—has imbibed the grateful moisture, and given liberty to the thousands of animalcules that dwell upon and within her. Good times for the chickens; natural food and natural medicine. Now they will grow. And our good, intelligent, but somewhat grumbling man, what will he say? For some time drought has been the cause of everything that went wrong; he has lost his stock in trade, but after another showery week he will shake his head, talk despondently about wet, and wonder when we shall have any sun. In our leisure we have kept a record of our poultry curiosities, and we find, in answer to the question why there were so few eggs, the following replies within a week:—"Too wet," "Too dry," "Scorching sun," "No sun at all," "No faith in pullets," "Hens too old."

We will assume that all hens and chickens are out of doors to enjoy the advantage of a grass run, and the varied natural food to be found there; but it will now be necessary to shift the position of the rips a little, as there is a probability of broken weather. While there was no rain the little hollows and the bottoms of banks were advantageous situations, but they should now be avoided. Little knolls and banksides will be better, as they will not hold rain. A dabbled roosting-place is bad for chickens. Where grass is short and fed-off, of course a rip may be put anywhere, the only precaution necessary is to turn the back to the wind every night; but where grass is long, and growing as it will now, comparatively bare and thoroughly dry spots must be chosen. Chickens of six or seven weeks old soon perish in long grass if they are overtaken by a heavy shower. The neglect of these simple precautions once cost us in a four-acre field, thirty-seven out of fifty forward Spanish chickens.

PROLIFIC EAST-INDIAN DUCKS.

I HAVE a pen of East-Indian Ducks hatched last year. After laying about twenty eggs they commenced sitting. One of them hatched nine young ones on Friday, May 1st, recommenced laying on the Tuesday morning following, and has laid every day since. I am told that this is not usual; and if it is as unusual as I suppose it to be, my brother poultry-fanciers may feel an interest in knowing it.—JOHN DUTTON, *Bunbury, Tarporey*.

[It strikes us this is a very unusual occurrence. It is one we have never met with in our experience. The earliest case we know of was one in which a hen took to laying when the chickens she had hatched were only a fortnight old. In that case she immediately became a bitter tyrant to her family, and we were obliged to take them from her; as when the hen is occupied with laying the foundation of a new family, the noses of the previous one are generally broken. We shall be glad to hear how this *rara avis* conducts herself towards hers; also, whether she lays in a nest, or drops her eggs about. An account should be kept of the number.]

DRONE-BREEDING QUEENS.

I BEG entirely to disclaim any idea of attempting, as Mr. Lowe expresses it, to upset the general belief of bee-keepers as to the worthlessness of drone-breeding queens. It is only under very exceptional circumstances indeed that one of these is tolerated either by "B. & W." or myself. In a general way a great multitude of drones is a great evil, and under ordinary circumstances

I fully indorse the conclusion arrived at by the German bee-keepers at Potsdam.

Whilst admitting that fully-developed drones are physically perfect by whatsoever queen they may be produced, Mr. Lowe, nevertheless, considers that small drones bred in worker-cells must be imperfect, because female bees become so when bred in a similar manner. In this opinion he is, however, completely mistaken, since I have proved by anatomical investigation that the male offspring of a virgin queen bred under these disadvantages are yet perfectly capable of fulfilling the part allotted to them.

I think it will be conceded by all who have done me the honour to peruse my articles, that I confine my attention principally to facts, and meddle very little with theories. I follow neither Dzierzon nor any other man one step farther than my own experience shows him to be correct. Having thoroughly investigated the subject of parthenogenesis in the honey bee I have proved it, and, therefore, have no hesitation in proclaiming it to be an established fact; beyond this I do not go, and have nothing whatever to do with any theory which may have been propounded as tending to elucidate what is undoubtedly one of the greatest of Nature's marvels.—A DEVONSHIRE BEE-KEEPER.

STEWARTON OCTAGON HIVES WOODBURYISED.

It is now some years since, like your Oxfordshire correspondent "UPWARDS AND ONWARDS," I was much struck at the grand display of octagon supers in a Glasgow window: and stepping into the shop for a more minute inspection, I found the counter and shelves laden with like trophies of apian skill. Selecting a box, the straightness, dazzling purity, and rich massiveness of the combs were quite tempting to behold. I inquired its cost, and was rather taken aback by the seller, after a glance at the weight and a little mental calculation, informing me it was "exactly three guineas." Contrasting in my mind's eye such results, my little glass supers (Payne's new shape) seemed small indeed. Failing to elicit any information further than that the entire stock was drawn from Ayrshire, where alone the hives were made and the system of management fully known, I resolved to make a tour of discovery through the neighbouring county. This resolve I shortly afterwards carried out, bearing introductions to a few of the merchants' principal furnishers, and returned with a supply of hives and an addition to my store of apian knowledge in many important particulars at which the best works I had read on the subject failed even to hint. I also received a deep impression not easily effaced of the thoroughly practical acquaintance, gained by long experience, of the great majority of Ayrshire bee-keepers on all points of management, their enthusiasm, and the fine fraternal spirit of all, from the humble cottager up to his stylish neighbours.

The Stewarton-hives came up fully to what I had anticipated during the comparatively capital seasons with which we were then favoured.

There was one part of these hives I thought open to objection—seven bars $1\frac{1}{2}$ inch broad in the breeding-boxes. This breadth, although most suitable for supers, was indefensible in the others on any other plea than that in these no guide-comb was used, the inmates being allowed full liberty to twist about their combs according to their fancy. Still I found that the broad bars lessened the communications between the several boxes composing the set; and at my suggestion the number was increased to nine $1\frac{1}{2}$ broad, and in some eight, the six central being $1\frac{1}{2}$, and the two end ones $1\frac{1}{4}$. Latterly, as a still further improvement, I suggested omitting bars altogether in the second breeding-box, thereby throwing open to the peregrinations of the queen uninterrupted access to a much larger area of comb, as has been already explained in the adapter plan in No. 5, New Series. In the hives sent out for the present season I find yet a further change, which has prompted these remarks—viz., the number of bars increased to ten of the narrow Woodbury pattern, and duly ribbed, kept in their place with small brass screws, and consequently all moveable. On making inquiry I found that this improvement, like the preceding ones, had only been adopted after various tests, which terminated with the best results; and I have, therefore, much pleasure in congratulating your excellent correspondent "A DEVONSHIRE BEE-KEEPER" on such a satisfactory proof of the value of his invention, emanating as it does from so thoroughly practical and trustworthy a source.

When on this subject I may mention, that a still longer comparative trial of octagon and square hives side by side, confirms the opinions I formerly expressed as to the superiority of the first-named. At the present moment I have a very striking proof in my own apiary, consisting of six stocks, two in octagon, and four in square hives. Three of the latter were strong colonies that did not swarm last season, while the octagons in one case did, but the bees were beaten out of their own hive at the end of the season into an empty one to give place, with the view of saving a good queen and a small train of followers; and yet these two hives, started under such disadvantageous circumstances, (the combs of the one being fabricated almost solely from sugar), now outnumber in population any two of their square competitors, having in addition their combs much better kept; both advantages to be accounted for by the better concentration of heat in the octagon form, and all the more observable after the very unusually cold bleak April we have just passed through. During summer heat the shape of a hive is of much less consequence.

To such of your readers as formerly doubted the accuracy of the above hypothesis, or any curious to peruse the arguments at length in favour of the octagon form, I would refer to page 141 of "Thorley on Bees," published 1765; and, should they wish to go further back, to the 80th page of that quaint old book published by Moses Busden, the apothecary, in 1687.

This last-described improvement overcomes almost entirely the only valid objection brought against these hives for the experimental purposes of the day—viz., the unequal length of bar, as the six central bars are now all of one length and moveable, and, of course, contain the great bulk of the brood, the outer ones being almost exclusively used for storing honey. I shall now be able to work together with much greater facility my octagon and square hives, which have all along been a principal inducement to keep the latter $1\frac{1}{4}$ inches square.

I have only to add, what I have more than once stated, that in my opinion Stewarton octagon hives are the cheapest and best wooden hives procurable for practical bee-keeping, particularly to such as are located in a fair honey district.—A RENEW-SHIRE BEE-KEEPER.

MEETING OF GERMAN BEE-KEEPERS AT POTSDAM.

(Concluded from page 286.)

V. *Why have bee-hives recently been often changed from the ständer to the lager form?**

Herr Kritschke, who propounded this question, asked Pastor Dzierzon to state the reason which had induced him to change from the ständer to the lager form, and to construct the twin-stock.

Pfarrer Dzierzon said—Although I did not moot the question, I soon found on perusing it that my twinstock had been taken into consideration, and that it might really be put as follows:—"Why is the twinstock to be preferred to other hives?" Convenience in placing it is what especially induced me to construct this hive in the form of a lagerstock. It does not require an especial stand or bee-house, which frequently costs more than the stocks are worth which are placed in it. Also, twinstocks can be placed in any favourable situation without preparation, which is very convenient for transport. Then the lagerstock has always been considered richer in honey; nor does the honey require refining, since brood, especially drone-brood, is restricted, because as is known, drone-cells are generally found in the lengthening of the combs downwards, which the shallow lagerstock does not admit of. Even worker-brood in the lagerstock cannot be unduly extended at the expense of the honey stores, because the queen when egg-laying does not readily remove to side-combs which are free from brood, whilst on the same comb in which she has commenced laying she immediately deposits an egg in every cell which the bees make downwards.

Other speakers advocated the same opinions.

VI. *Is there any paint which will keep straw hives absolutely waterproof?*

Herr Gruwe recommended a composition formed of five parts wax, one part Venetian turpentine, and one part sulphur laid on warm.

Herr Gutknecht.—One part loam, two parts cowdung, one part wood ashes well kneaded together and plastered over the hives immediately. Afterwards they may be varnished.

* The "ständerstock" is a tall, upright edifice, whilst the "lagerstock" is of a longitudinal form with the entrance at one end.

Lieut.-Col. von Wedell.—Take coarse blotting-paper, make it into a pulp with hot water, and mix it well with clay.

Herr Schindler.—One part of curd mixed with one part buttermilk, then one part English cement, and two parts sifted sand are added. This is thinned with buttermilk or water so that it just admits of being worked, and must be continually stirred whilst being laid on. At the expiration of half-an-hour another coat should be given, which forms a waterproof covering of a grey stone-like appearance, and which becomes as hard as stone when painted over with linseed oil, with which any other colour may be mixed. Wood ought not to be planed, and for roofs red lead may be substituted for sand.

The President asked gentlemen to try these various compositions and report the result.

VII. *What are the advantages and disadvantages of allowing bees to build combs at their own will?*

The discussion on this subject was confined to debating the propriety or otherwise of allowing bees to build combs according to their own fancy in the "honey-room" (which answers to our supers), and presented little to interest or instruct English apirians.*

This closed the first day's proceedings. At three o'clock two hundred bee-keepers dined together at six tables under trees in the open air, and the rest of the day was spent in viewing the sights of Potsdam, which were thrown open to inspection.

SECOND DAY.

VIII. *Of what importance is pollen in the preparation of food, and in nourishing the three different kinds of individuals in the bee-hive?*

This query was introduced by Baron von Berlepsch, who propounded the novel theory that honey contained nitrogen in addition to carbon, hydrogen, and oxygen; or if not, then the modern doctrine of physiology that nitrogen is necessary to the formation of animal bodies is untrue in respect to bees, since he found they could pass the winter in health, and rear brood during that time on honey only. This doctrine was, however, controverted by Pastor Dzierzon, Count Stosch, and others, who upheld the correctness of the analyses which excluded nitrogen from the constituents of honey, and contended that bees must have access to pollen in order to maintain them in health, and to enable them to bring their young to perfection.

IX. *Can the diligence of bees be increased? and, if so, by what means?*

Count Stosch said the bee is always as diligent as she can be, but not always as she could be if circumstances permitted. By removing hindrances her industry is increased. The diligence of bees in its nature of an impulse to work cannot be enhanced; the effect of that impulse may be increased, but not the impulse itself. After referring to the loss of a queen decreasing their activity, and describing the mode of remedying this evil, the speaker said he considered the insertion of empty combs to be one means of increasing the industry of bees. He also recommended the artificial division of overstrong stocks. Natural swarming, he pointed out, diminishes their activity in a threefold manner—1st, Bees work but little whilst preparing for swarming; 2nd, In the act itself, which is sometimes frequently repeated, much valuable time is lost; 3rd, The queen must limit oviposition in order to be able to fly. Large honey-stores may diminish the activity of bees in the same manner as excess of population and great heat. In these cases some honey or brood-combs should be removed. Lastly, the most natural, the easiest, the most indisputable, and the most effective means of increasing the diligence of bees is to improve their pasturage. The speaker briefly mentioned three modes of procuring a harvest for bees when nature does not offer any, and by means of which bees have the opportunity of working when otherwise they must be idle. These means are—Giving water in winter and early spring, feeding with flour, and speculative feeding with honey.

X. *May worker and drone eggs recently laid in the combs be safely sent away, and for how long a time?*

Herr von Wedell related an instance in which worker eggs in the comb had been safely sent to a distance, and afterwards hatched, every egg being covered with a small portion of honey.

Pfarrer Dzierzon doubted the fact, considering that the presence of honey in the same cells would cause the bees to destroy the eggs when presented to them; but stated that eggs would remain uninjured for a period of from eight to fourteen days.

* Herr Schulze advised compelling bees to make thick combs which are unfit for breeding, and recommended side communications.

His experiments proved—1st, That eggs may be transported by land-carriage without becoming detached from the bottom of the cells; 2nd, That the vital principle remains latent in the worker egg during a longer time when out of the hive than it would do if left in it; 3rd, That worker eggs are hatched earlier in a high temperature than in a low one.

XI. *How can bad honey be purified?*

Herr Blume said good honey can be easily purified by clarifying it with albumen and straining through a fine wire sieve or a coarse cloth; bad honey can only be purified by means of tannic acid or carageen moss, which is done in the following manner:—To 15 lbs. of honey are added 30 grains of tannin dissolved in water. The whole is thinned by the addition of one-third to one-half part of water, and boiled. After this it is slowly poured through a vessel with a perforated bottom covered with bone charcoal and washed quartz, care being taken that it does not run down the sides. When filtered in this manner the honey is fit for making mead or wine. Bad honey may, however, be entirely restored in the following manner:—To 20 lbs. of inferior honey (heath honey for example) add a drachm of carageen moss; when this is stirred until thoroughly mixed it must be boiled in a water bath, and all impurities will rise to the surface. The pure honey underneath is then carefully drawn off through a tap inserted near the bottom of the vessel, and will be found perfectly clear and bright.

XII. *How can a stock be compelled to swarm early?*

For this purpose keeping strong stocks and feeding was recommended; but with regard to the size of hives a difference of opinion prevailed.

Baron von Berlepsch said, I have never found—1st, That bees with a queen of the current year made many drone-combs; 2nd, That a queen of the current year laid many drone eggs; or 3rd, That a queen of the current year has led off a swarm.

The thirteenth question, "What important discoveries have been made in bee-keeping during the past year?" was not debated for want of time.—A DEVONSHIRE BEE-KEEPER.

OUR LETTER BOX.

COCHIN-CHINA COCKS PARALYSED (*M. A. C.*).—The usual cause of these birds losing the use of their legs, is the rupture of a small blood-vessel on the brain. This, generally, is occasioned by the birds being too fat. A table-spoonful of castor oil, and a diet of soft food, chiefly boiled potatoes, abundance of lettuce leaves, and freedom from excitement, whether from fright or other cause, is the best treatment, but it requires perseverance, and there is no certainty of success.

HEN EGG-BOUND (*A. N.*).—Your Golden-spangled Hamburg hen is probably over-fat. Give her a dessert-spoonful of castor oil; feed her on boiled potatoes and a little barley-mead mixed with them, and let her have plenty of lettuce leaves. Continue this until she lays regularly, and then be careful not to give her food that is too fattening.

ILLNESS OF COCHIN COCK (*Inquirer*).—There is something that offends in the inside of the Cochin cock, and he will not be better till it is removed. This can only be done through purging. You must at once give a table-spoonful of castor oil. Being as weak as you say, it is more than likely he will require to be kept up a little. You must give him bread steeped in strong ale, and you may give him the yolk of an egg now and then. It should be given raw, and be poured down his throat. When his excrement is firm and figured—dark brown tipped with white—he will be well. The purging must be continued till no more green slime comes away.

DUCKLINGS DYING (*Outlands*).—As they seem to die without a cause, and you do not state a single symptom, how is it possible for us to divine the source of death? Forty-five out of fifty-five dying thus unaccountably, suggests that something is eaten by them that is poisonous. They are not difficult to rear. When first hatched curd is the best food for them; and when three or four weeks old ground oats mixed in water with a little fine gravel in it, and whole oats occasionally for a change. If the ducklings are in a confined space they should have sods of growing grass in their water.

INCUBATOR.—We hear from a correspondent, that an incubator is to be sold on very reasonable terms, and that full particulars may be had from "Mrs. Beatty, Heathfield, Wexford, Ireland."

BOOK ON BEES (*E. R. S.*).—In a few days we shall publish a new edition of "Bee-keeping," very fully illustrated. Payne's hives are the cheapest and simplest. They can be had of Messrs. Neighbour. Your other questions we will find room for next week.

LONDON MARKETS.—MAY 18.

POULTRY.

There is still a good supply of poultry, especially of small chickens, consequent on the mild winter we have had. Trade is dull, and the demand very small for the season of the year.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 67.6° and 44.6° respectively. The greatest heat, 91°, occurred on the 28th, in 1847; and the lowest cold, 32°, on the 31st, in 1857. During the period 148 days were fine, and on 104 rain fell.

THE AMARYLLIS AND ITS VARIETIES.

IPPEASTERS are now generally to be found amongst collections of plants, and are increasing in public estimation every year. Those species which have been sent home from the West India Islands have reproduced seedlings infinitely superior in substance, more brilliant in colour, and of finer formation in both sepals and petals; which must be set down to the credit of in-and-in breeding and careful selection of parentage. Nor must

we forget the powerful influence exercised by the pen of Mr. Beaton, from the very time THE COTTAGE GARDENER was in its infancy, in stimulating a zest towards their more extended cultivation. His various papers, although I am only speaking from recollection, have a very distinct impression upon my mind, exhibiting as they do a perfect acquaintance with the whole genus, and conveying valuable practical hints on their cultivation. No one, not even excepting Dean Herbert himself, knew the varieties by headmark even to their minutest parentage better than he; and, as Mr. Fish has well expressed in one of his communications, his dissertations on the genus and its subdivisions constitute of itself enough to perpetuate a name.

There is first and foremost *formosissima*, a most beautiful velvety crimson sort with its peculiar contraction of the lower sepals which, by the way, has hitherto defied, so far as I know, all attempts at hybridisation. I have tried it in various ways with first-rate pollen, and *vice versa*, but to no purpose. This sort is invaluable for spring decoration, flowering generally during April in a cool house. It is an old-established favourite grown in many places where no other variety is to be found. With all the first-rate novelties there is none possessing much better substance; and therefore it has a decided claim upon our sympathies—besides it is a great favourite with the ladies.

Then there is *vittata*, another comparatively hardy sort, which has been the parent of a great many good seedlings, of which we believe *Johnsoni* is one of the oldest. The latter variety has reproduced numerous forms almost an exact counterpart of itself, the best of all the strains we have ever seen of it being *Johnsoni précieuse*. This variety excels the parent in quality and substance of bloom, and is likely to make an excellent sort to breed from. We have pods of it now by the pollen of *marginata conspicua*, which will in all likelihood have some progeny fair to look upon.

Then there is *solandraeflora*, a long-tubed sort, very interesting and beautiful, which now also has a good many representatives, of which *Graveana*, *Crocea grandiflora*, and *Delicata* may be said to be the best and most pro-

No. 113.—VOL. IV., NEW SERIES.

minent. *Marginata grandiflora* also partakes of this same type, and all are exceedingly large as individual flowers and free growers.

There is *aulica*, an evergreen, requiring exactly the same treatment as *Vallota purpurea*, but rather more tender, and would suffer in a temperature which *Vallota* would tide over with impunity. If there is any use in recording a protest against the nomenclature, not universal nor general, but special as in this instance, why is this brilliant orange-scarlet *Vallota* called *purpurea*? There is nothing about it, so far as I can see, to justify the name; and the sooner it is changed the less queries will be suggested about it. Occasionally people who have no pretension to the knowledge of plants have been surprised why it should have been christened with a meaningless cognomen.

It is strange that this *Vallota* will not intercross with any of the *Amaryllises*. I have dozens of times tried it upon the stigma of free-setting sorts, such as *Ackermanni pulcherrima*, *Marginata conspicua*, *Johnsoni*, and others, with no good results. I was the less surprised at no effects on such sorts as *organensis*, *Ackermanni*, and *grandiflora*, because the scape of any of them never produces more than two flowers; but on such sorts as those above mentioned, which often produce four flowers, there was more room for comment.

One variety which found its way into our collection by a fortuitous occurrence, and which turns out to be something very distinct and fine, throwing up, as it has done this season, two flower-scapes, each producing eight flowers, seemed to be a sort that would suit *Vallota*; but after two or three careful pollen-applications both ways, there is nothing signified but barren results. I have, therefore, come to the conclusion that *formosissima* and this *Vallota* will not hybridise; and I should like very much to know if any of the readers of the *Journal* have ever tried and been successful with either or both of these. I know Mr. Beaton declared long since that neither he nor anybody else could hybridise *formosissima*.

All the other sorts, with one or two unimportant exceptions, seed freely by intercrossing, and thousands of seedlings can be raised at will.

The following are the sorts that have been proved and found to be the very best out of a numerous collection.

Ackermanni pulcherrima.—A very intense crimson of extra fine substance, producing four flowers from the scape. Form very good. This sort is easily known from having a round flattish bulb, something like the form of the Danvers Onion.

Ackermanni.—This is a bi-flowered sort, possessing a vigorous habit, and producing flowers often measuring 7 inches across. The form of this is not of the first style of excellence, but it is altogether a good ornamental sort of rich substance.

Bierii.—This is one of the finest-formed of the whole race of them, but a little deficient in substance. Colour white and pink, beautifully suffused; something in the way of *marginata conspicua*, but paler. It is a very free bloomer, producing from four to six flowers in the scape.

No. 765.—VOL. XXIX., OLD SERIES.

Its foliage is very handsome, being of an olive-brown hue with faint purple veining, and it is distinguishable at first sight, although not in bloom.

Crocea grandiflora.—A fine orange-scarlet of good substance, with a dash of white at the base of the sepals and petals. Very showy.

Delicata.—Scarlet and white, with fine ornamental foliage, being banded with a broad undefined stripe of white down the centre of each leaf. Much the best of this colour. It is, however, rather a shy breeder, and is somewhat refractory, if I may so use the expression, in its reproductive tendencies.

Gigantea.—A very distinct sort of good form, the nearest approach to a scarlet self of any kind known to me. It grows freely with liberal treatment, but is about the easiest to kill of any in cultivation.

Graveana.—An immense-growing sort, generally producing four flowers of great size and good substance. It is the best fellow for Ackermanni in point of vigour of growth and size of bloom of any in our collection. It is an improvement upon *Crocea grandiflora*, and I reckon it much the best form and substance of the *Solandraeflora* section.

Holfordi.—Scarlet and white well "washed" together, producing an agreeable whole. Substance very good, and form also. This is a tolerably free grower to be so much in-and-in bred, and may be safely added to any collection.

Intermixta latipetala.—This is a very good crimson-scarlet self of the four-flowered section, rather shy in habit, and possesses no great tendency to multiply itself by offshoots.

Johnsoni précieuse, a fine, broad-petalled and sepalled variety of Johnsoni, of rich substance, with a band of white, much more clearly defined than in the old variety, running down the centre of each petal to the extremity. This and another one named *vera*, are much the best of the Johnsoni strain.

Marginata conspicua.—This is an exceedingly free-growing and prolific-flowering sort of the most handsome appearance, which everybody who grows bulbs should have. It is a white ground colour feathered with rose and crimson stripes, of excellent substance and good form. It seldom produces from the scape more than four flowers; but it blooms freely over the season.

Marginata grandiflora.—This is a long-tubed, very pale variety, rather more delicate than the other marginata, but is well deserving of a place. Ground colour white, with faint rose stripes over all the surface.

Marginata venusta.—It is not easy to distinguish this from *conspicua*, but it is the more rare, and, upon the whole, the better formed of the two. Some attribute their difference to a slight perfume in favour of the one in question, but my olfactory nerves were never sensible to any such sensation.

Monsieur Van den Hecke.—A large bi-flowered sort of the grandiflora order. Its form is good, but it is deficient in substance.

Psittacina Johnsoni.—A large, free-flowering sort, crimson and white finely blended, of good substance, and excellent form. This variety is probably the most prolific in flowering of the whole race, throwing up as many as three stems from one bulb, generally producing four flowers on each.

Psittacina vittata.—This is a lighter variety, partaking of the same character as the above, but more allied to the true vittata than the preceding one. Both, however, are excellent sorts, of fine form.

Venosa grandiflora is a very handsome-growing species, producing numerous offshoots. Flowers finely veined with crimson; large and fine.

Wheeleri.—This is a very wide-spreading sort, of very rich crimson colour and good substance. It is straggling in petal and sepal, but measures somewhere about 7 inches across, and is, therefore, well adapted for decorative purposes, although its merits will not pass muster before the Floral Committee.

We have recently added *Eclipse*, *Hawkensiana*, and *Unique*, which have passed muster as acquisitions in their way.

Upon the whole, the field is promising, for judging from the acquisitions that have been made when their cultivation was only limited to a few enthusiasts, we may anticipate great things now that ladies and gentlemen see their decorative value, and the ease with which they can be cultivated.—JAS. ANDERSON, *Meadow Bank, Uddingstone*.

two years, and wishes for instructions how to treat it. To this we may say, that if the climate and situation be a moist one it will not flower so freely as when these conditions are reversed. If the plant appears too rampant, cutting-in the roots may do some good, and thoroughly draining any superfluous water away, at the same time supplying the plant with a drier and poorer soil. Generally speaking the Banksian Rose, both white and yellow, does best against a south wall, but we have it against pillars also, but it does not flower so freely. In pruning it is best to cut away all the gross long shoots, and shorten-in the mere spur-looking ones which produce the flower. We usually prune ours twice, once about the middle of June, and again about the end of August, or when the growth of the season is finished or nearly so. Observe, it is the short-jointed, wiry-looking little shoots that produce the flowers, not the long ten or twelve-foot rods which we have often had, and which are useless excepting to increase the size of the tree when wanted. We do not expect any treatment whatever will have so good an effect in producing flowers as a fine, hot, dry autumn, but helps like the above will conduce to that; and, if not successful, we fear the evil lies in something beyond the reach of cultivation or artificial treatment.—J. R.

FOLIAGE VERSUS FLOWERS.

"WHAT new thing is coming out this year?" is a question that one flower-gardener puts to another, after the usual greeting and comments on the season and its peculiarities.

Every year certainly either establishes the reputation of something fresh, or, it may be, revives the character of something that had been lost sight of; and what is 1863 going to do for us? The advertising columns of gardening periodicals will, no doubt, offer many attractions in the way of new or improved varieties of plants already in cultivation, and possibly some new species as well as something startling may be put forth. The public are, however, somewhat wary of anything having a too-high-sounding character. Progress now-a-days is often obliged to be content with slow and gentle advances.

A really new species of plant may be a great acquisition, but an improvement in a Scarlet or variegated Geranium can hardly be expected to be many degrees in advance of kinds that we already possess. Still, as we are perfectly aware, perfection has not yet been arrived at. Then, what new acquisition is 1863 to present us with?

Last year I gave a favourable opinion of Mr. Veitch's *Amaranthus melancholicus ruber*, and the way in which the plant turned out at the end of the season confirmed all that I said in its favour. The new *Cerastium* that was introduced last year was variously received; but I cannot say I am sufficiently acquainted with it to give an opinion of it. At best it does not seem to differ so much from the former one as to be worthy the distinction of a separate specific name.

Last year, like most others, was favourable to a certain class of plants more so than to the others, and amongst those that did well here were yellow *Calceolarias* and *Lobelia speciosa*. The former were especially very rich, and the latter scarcely less so, both being decidedly better than I ever remember them to have been before—that is, they bloomed profusely, and continued for a much longer period than usual. I cannot say the same of Scarlet and other flowering Geraniums. They grew well enough, and at one time were very gay; but it was late in the season, and the bloom did not last long. Variegated Geraniums did better, I might say particularly well; but *Verbenas* fell so far short of their former reputation, that I expect both they and *Petunias* have lost caste considerably. *Gazanias* did pretty well, but most of the *Tropæolums* ran too much to leaf—the early part of the season was too moist for their flowering. The reports of other persons may, perhaps, be different from the above, certain localities being favourable to the well-being of certain plants, to which another place is not; but the general features of a season tell everywhere. 1860 was wet and unfavourable in all places, while the preceding two seasons were the reverse, and we were induced to try many tropical plants out of doors that had never been thought of before. Fields of Chinese Sugar Cane waved in the breeze, and plants flowered and ripened fruit outside that rarely did so before; and flower-gardeners in their anxiety to introduce novelties into their beds tried many stove plants previously regarded as almost too tender to stand in the greenhouse in summer. Some limit will, however, always restrict this. Delicate plants like *Begonias*, *Torenia asiatica*, *Pentas*

YELLOW BANKSIAN ROSE NOT FLOWERING.

A LADY writing from Bandon, Ireland, complains of a fine plant covering a wall 18 feet high not flowering during the last

carnea, and *Coleus Verschaffelti*, may succeed tolerably well in hot summers, but they cannot be expected to do so in an average one, and still less so in a wet cold season. The last-named plant was strongly urged as one suited to the flower garden, and certainly its appearance in-doors, and the facility by which it may be increased, lead one to form great expectations of it; but in the places where it was tried out of doors last year that came under my notice, it merely existed; that it thrive and looked well was more than could be said of it when I saw it. But it is quite possible if we have a hot summer again, that both it and many other things may do well. This, however, is not enough to establish the utility of such plants for all seasons; but as every year adds to our list of such novelties, it is likely we may have all the hues of this *Coleus* transferred to some other plant possessing the good qualities of the *Perilla*. While on this subject, I may say that the old Prince's Feather and Love-lies-bleeding are far from despicable members of the floral world, no annual that I am acquainted with continuing a longer time in an ornamental condition, and both deserve more attention than they often receive.

As regards the question of what will prove to be the great attraction of the present year, I will also venture to give a sort of qualified answer, and say that I believe the greatest addition to most gardens around London will be the more extensive cultivation of *Centaurea candidissima*. Its appearance in the few places where I have seen it was such as to commend it to every one having a flower-bed. That something more decidedly new may be forthcoming I have no doubt; but whether anything more really useful than this, has yet to be determined. I hope nurserymen and others who propagate for the million will let us have it at a reasonable rate. Hitherto, kept as it often has been as a potted plant, its increase has been slow. Now, as it is wanted more extensively, its propagation must be accordingly.

I am induced to offer the above rough outlines of last year's features, as exemplified in the products of the flower garden, and also with a view to call attention to the claim of the last-named plant, which hitherto has not been so generally recognised as I expect it will be hereafter. At the present time, judging from what I have seen, I have no hesitation in putting it at the head of all our white-leaved plants, including, of course, the variegated ones. The shape of the leaf, though not better than that of *Cineraria maritima*, is, nevertheless, good, as is likewise the habit of the plant, and I shall be much disappointed if it do not become one of the most fashionable plants of the day. It would, nevertheless, be advisable not to rest satisfied with this plant alone; improvement even on it may be possible, and something still more white may be forthcoming in time.

Other colours in foliage ought also not to be lost sight of, and some tints not hitherto thought of, may, perhaps, be brought out, so as to render the uncertainty there is in adverse seasons of obtaining bloom a matter of much less importance than now; and though the many beautifully graduated tints of the *Verbena* from white up to the darkest maroon may seem impossible to be represented in foliage, it is only necessary to say, that both extremes named are duly and truly imitated in colours of foliage, and time may possibly supply the remainder.

To those who doubt the possibility of foliage attaining pre-eminence over flowers, which the above remarks may imply as being not unlikely, I would just ask our readers to look round them, and see the proportion which foliage bore to flowers in 1862 compared with what it did ten years before that time.

Variegated *Geraniums* have been multiplied exceedingly since then, and various other variegated or white-leaved plants introduced, or their cultivation extended; while *Purple Orach*, *Perilla nankinensis*, and the new *Amaranthus* from Japan, have given new features altogether. That these plants are only the precursors of others giving other colours, I have not the least doubt. Whether it would be advisable to hastily abandon flowering plants is another question. Most likely people would not do so; but where early and long-continued appearances are concerned, in adverse seasons and ungenial situations the encouragement given to foliage cannot but be recommendable. Certainly the preference should never be on the side of foliage when flowers offer equal advantages. But as the planting-public are supposed to be the best judges, it is needless saying more than that I believe the introduction of plants with remarkable foliage either in colour or appearance will be most sought for after the present season, improvements on existing varieties of flowering plants receiving less attention.

Anything really good, whether it be new or a resuscitated

old plant, will always receive a due share of attention; and if I ventured to encourage the more general adoption of a plant likely to do good service I would say, By all means plant the one above alluded to—*Centaurea candidissima*—more extensively. If the ardent hybridiser wants a plant in which to work a revolution let him try *Lobelia speciosa* or its kindred species, and see if he cannot turn out as good a scarlet as he has a blue, leaving the habit and other features of the plant the same. Few plants were more generally admired in the past season as well as in the previous one than *Lobelia speciosa*, and I think that if its flowers could be dyed a bright scarlet it would drive the *Verbena* from the field.

That it is possible for this to be accomplished I have no doubt. Slowly and by degrees most of the popular varieties of fruits and vegetables, as well as flowering plants, were perfected, and cannot the same be done with *Lobelia*? Previous to the last two or three years the *Lobelia* only occupied the position of a second-rate bedding plant; last year it was unquestionably in the front rank, and that further honours are in store for it I have no doubt. Its compact habit, adaptability to most soils and situations, and the facility with which it may be propagated, all combine to render it acceptable. Without detracting from the merits of other plants, *Lobelias* have certainly been in the ascendant; and being capable of further improvement are likely to rise. The season of 1863 will, no doubt, present other novelties; and all that are good will be acceptable, and have full justice done to them.

J. ROBSON.

JOTTINGS FROM PARIS, 1863.

NO. 1.—L'EXPOSITION DE LA SOCIÉTÉ IMPÉRIALE ET CENTRALE D'HORTICULTURE.

"NOTWITHSTANDING that the Exhibition is open for so short a time, we hope that the large number of visitors may repay the Society for their skill and enterprise." In some such terms did *La France* speak of the Exhibition of the above Society, at which I had the honour of assisting, as our French friends term it, on the 9th of the present month of May. And what is the *short* time, do our exhibiting friends imagine, for which this said Exhibition was open—"from 2 to 6 P.M.?" Not at all: it was only open for seven days, from May 9th to the 16th inclusive; and more than this, the Judges had had the 8th all to themselves, for they were not called upon, as those on our side of the water, to get through their work in a few hours; but a whole day was given to their arduous labours. Now, this is taking matters very much as the French seem to take business in general, in a very free and easy sort of a way; but this "week" is an improvement on what it used to be. The Exhibition was held last year in the Palais d'Industrie, or, as it is now more generally called, the Palais des Champs Elysées, during the time that the exhibition of the works of living artists was being held; but as the Minister of Public Instruction insisted on its being kept up as long as that Exhibition—about two months, the exhibitors at last rebelled; and rather than lose their plants, determined to hold it elsewhere, and entirely on their own responsibility. In this they experienced some difficulty. The Champs Elysées was forbidden ground, as no more space was to be occupied there than at present, and it was necessary to obtain a spot in some central position. After considerable difficulty, a vacant space in the Rue Chaussée d'Antin, off the Boulevards, and, in fact, a portion of the ground which is to be hereafter appropriated to the Grand Opera House, which is now being built, and which will be the finest in the world, was selected; and on this the ingenuity and taste of the commission was exercised to make it fall in with the notions of the Parisians as to what a horticultural show should be. It will be at once seen that the fact of having a show open for a week, would in itself make a very material difference between ours and theirs. But there are other reasons which tend to this, a main one being the want of that extensive love of flowers which prevails in England; not but that the French love flowers, but they love them for bouquets, for house decoration, and for effect—they do not love them so as to give themselves trouble in their cultivation. There are very few amateurs in France such as we have in England, and many who go under that name are really persons who, although not growers for sale, grow some favourite flowers for those who are. We are accustomed to see in our own shows the nursery element largely manifested, but the amateurs run them very close, and are numerous; but at the French Exhibition they were almost entirely absent, and whether in fruit, flowers, or vegetables, the

productions came from those who are commercially engaged in the pursuit. There is one other reason which I think also adds to this difference, indeed it grows out of the last—viz., that as a rule the French nurserymen do not keep specimen plants, they cannot afford to do so; and hence the plants they send are diminutive indeed compared with those which come to our great exhibitions.

But to return to the Exhibition. The space enclosed by the tent was, I should suppose, about as large as that occupied by the one under which the Royal Botanic Society is held every year, the ground, however, being level instead of undulating. On entering the tent there was spread out before you a pretty grass garden, filling the centre of the parallelogram which the tent comprised, and the grass having beds arranged in it, in which the plants were plunged in pots: consequently, although occupying a tolerably good space, the plants in flower formed but a small portion of it; Yuccas, Norfolk Island Pines, Eucalyptus, and collections of Conifers being planted in the grass. A broad walk ran all round this grass garden, while a narrow stage of about 4 feet ran round the entire length of the tent. On this were arranged the vegetables, fruits, and some of the flowers, cut and in pots. On either side of the door as you entered there was a collection of Roses, contributed by Fontaine et Rénavol, of Versailles. These were standards, half-standards, and dwarfs planted out, and well arranged for effect; but the individual flowers were poor, and nothing of novelty beyond Madame Boutin and Vicomte Vigier, both of which seemed good flowers. There were two beds of Fancy Pansies, which had a pretty effect and suggested the desirability of their use for early spring gardens. The flowers themselves were not better, if so good as those by Mr. Dean and Messrs. Downie & Co. in our own country. Then there was another bed containing a collection of Pelargoniums, Verbenas, Cinerarias, and Fuchsias, amongst which the most noticeable was a collection of the new Italian Verbenas, from which I hope we shall obtain quite a new start, as they are striped, spotted, and mottled in the most curious manner. Not far from this was a charming little bed of one of the best bedding Verbenas I ever saw. It was raised by one of the numerous small growers around Paris, and is called Mademoiselle Lefebvre, a fine rosy crimson, very short-jointed, and one mass of bloom. It was, of course, in pots; but I shall be very much mistaken if it be not one of the best for the purpose that we have. Then there was a bed containing three varieties of Zonale Pelargoniums raised by M. Jactot, head gardener at the Château de Bagatelle, at Neuilly—Prince Imperial, which was let out this spring by Rougière-Chauvière; Fairy Labrousse, a fine salmon; and a white, which will, I believe, throw Madame Vaucher far into the shade. It is dwarf and very free-flowering, and seems to be a beautifully clear white. Of course, as to whether it will retain this out of doors is another matter. It was named Madame Barillet, and has passed into the hands of M. Rougière-Chauvière, who will send it out in autumn or spring next. There was a fine collection of tree Pæonies, from M. Dupuy-Jamain, some of which were truly enormous, and very brilliant in colour, but we fear they flower at a time when we could not rely much on them in our climate. Our kind and excellent friend, M. Margottin, of Bourg-la-Reine, had a nice lot of Azaleas; among them a very good seedling of his own, a clear white, and some neatly-trained standards.

At the further end of the tent were two collections of Conifers, from Messrs. Morlet, near Fontainebleau, who exhibited amongst others small plants of some of the new Japanese Conifers; and M. Honoré Defresne.

New introductions were exhibited by Messrs. Thibaut et Keteleer, Rougière-Chauvière, and Lierval, and comprised many of the new Japanese novelties introduced by Messrs. Standish and Veitch, and other plants of value, but nearly all in a very small state.

Orchids were contributed by Thibaut et Keteleer, Rougière-Chauvière, and Luddemann, the latter formerly gardener to M. Pescatore, but now a nurseryman. These collections were very different to those which we are in the habit of seeing: thus M. Luddemann's collection contained thirty-two varieties, but a space of 10 feet by 4 held them all. Few of the plants had more than one spike of bloom on them, and were very different from those which Mr. Williams, Mr. Warner, &c., send to our exhibitions.

Then there were three or four collections of Cacti, Melocacti, Agave, Aloe, &c.—a sort of thing quite unknown at our shows, but apparently exciting considerable interest in France. That

the plants were not very large may be gathered from the fact, that some of the collections comprised 230 varieties, and that a space of 10 or 12 feet by 4 held them all.

Cut flowers were sent in small numbers. There were two collections of Tulips and one of Pansies, which would have provoked the risible faculties of Messrs. Headly, Turner, Betteridge, or any of our Tulip-growers; and, of course, after the first day they exhibited a sorry spectacle of faded charms, of which, to tell the truth, they had but little at the best of times.

I find that my observations have run on, so that I must reserve my notices of the vegetables and fruits for another time, and, perhaps, it will be well to do so in connection with the markets, especially the Halle Centrale. It is sometimes said, "They manage these things better in France," and it is true of many things, but certainly not of flower shows. They did what they could with the materials at their disposal, and the taste for which they are proverbial was evident here. What they would do if they had the material that we have one cannot conjecture.

I may add that there were two English exhibitors. Mr. Arthur Henderson sent a plant of his Tropæolum Ball of Fire, and just at the last moment as I was starting off I cut off a number of blooms of Auriculas, and am bound to say that they excited quite a sensation, as the flower as we grow it is almost unknown in France. Nothing could exceed the politeness with which I was treated by all concerned—a rule to which one rarely meets an exception in matters connected with horticulture at home or abroad.—D., Deal.

MR. SALTER'S NEW DOUBLE PYRETHRUMS.

MR. SALTER, of the Versailles Nursery, Hammersmith, who is so celebrated for his admirable Chrysanthemums, has succeeded in producing a formidable rival to that flower in the shape of a race of double Pyrethrums, which in size and appearance bear a striking resemblance to Chrysanthemums—but with this difference, that they bloom in May and June. We saw these flowers under very disadvantageous conditions as regards weather—in a day when rain poured down, and the wind blew in heavy gusts, both of which circumstances must have detracted much from the appearance which the blooms would otherwise have presented; and yet we can say that they were entitled to rank among the most attractive flowers of the season; and although intended for out-door decoration, they might even be introduced into conservatories with excellent effect.

There are several varieties, all of which are not yet in flower; but the finest in our opinion is one called Versailles Defiance, which is a perfectly double ranunculus-shaped flower, fully 3 inches across, and of a light-reddish pink; Purple King has double flowers, some of them quite as large as the preceding kind, but with a high anemone centre, in colour of a dark purple carmine; Brilliant, also anemone-flowered, is 3½ inches across, and of a beautiful bright rosy carmine; Bride is rosy flesh and, like those which follow, is likewise of the anemone form. Pink Beauty is bright pink with a very high centre; Striated, rose striped with white; Album Plenum, 2½ inches across, bluish white; Madame Foucard, bluish; and Bridesmaid very delicate bluish pink. Princess Alexandra is a pure white, nearly 3 inches across and remarkably double; Amelina, purplish-pink; Hendersoni, a deep rosy red; and Rosa Alba bright rose with part of the petals white, the blooms measuring 3½ inches across. Charles Baltet is a large and very double rosy pink, while Thomas Massart is a very pretty delicate pink, and Defiance a very large and fine bright rose, the flowers being nearly 4 inches in diameter.

Taking a hasty glance over the houses, we observed among the British Ferns a variety of *Scolopendrium vulgare laceratum*, with the fronds very deeply cut at the edges, and forking; another variety, *polycuspis*, had the extremities much branched. The North American *Osmunda cinnamomea* was throwing out panicles, which are seldom seen in this country; and *Osmunda interrupta* was also in a similar condition.

In a house devoted to hardy variegated plants, a variety of *Sedum Telephium* or *Orpina*, called *picturatum*, had the leaves beautifully mottled with rose; *Oxalis corniculata picturata* was also very pretty, the leaves being brown mottled with bright pink, instead of being green. *Funkia japonica picta* from Dr. Siebold had large yellowish-green leaves with dark-green edges; and in *Convallaria angustifolia* (?), another Japanese plant, the leaves were prettily edged with white. Another ornamental-

foliated plant was a variety of the common Comfrey, endowed with a name of formidable length—*Symphytum officinale variegatum superbum*, in which the leaves had a margin of yellowish-white. *Artemisia maritima*, Mr. Salter states, forms an excellent cut-leaved plant for bedding-out, the foliage turning quite white when out of doors. We also observed a new *Centaurea* with woolly leaves, which measured 17 inches long by 6 broad, and which, we are told, become much larger and as white as those of *C. candidissima*.

Out of doors *La Pie*, or the *Magpie Pansy* was growing in one of the beds, and Mr. Salter gives it a high character as a bedder, and certainly its violet-purple flowers blotched on each petal with white; have a very ornamental appearance.

CRYSTAL PALACE FLOWER SHOW.

THE first of the great Shows at the Crystal Palace was held on Saturday last, and the day, though cold for the season, was fine, and even warm in the sun. But the weather is a matter which one need concern himself very little about when the Crystal Palace is in question; for you can go there, stay there, and come back from there without being from under cover.

The display of flowers, as might be expected from the liberality of the prize list, was most excellent; and what, no doubt, was equally satisfactory to the Company, the attendance of visitors was large, severely taxing, as we know to our grief, the excellent arrangements of the Brighton Railway.

Of Stove and Greenhouse Plants there were some excellent collections, several of which, however, having appeared at the Royal Botanic Society's Show, reported last week, had lost much of their freshness to our eye; and indeed not a few of the plants were what is termed "too far gone."

Mr. Peed, gardener to Mrs. Tredwell, Lower Norwood, was first with fifteen, among which were fine specimens of *Allamanda cathartica*, with its rich yellow flowers; *Ixora coccinea*, *Aphelaxis macrantha purpurea*, *Eriostemon buxifolium*, *Azalea Murrayana*, *Erica depressa* and *Cavendishii*, *Tetratheca ericeifolia*, *Chorozema Lawrenceana*, and *Pimelea spectabilis*.

Mr. Green, gardener to Sir E. Antrobus, Bart., Lower Cheam, who came second, had likewise an excellent collection, among which were the white-flowered *Dracophyllum gracile*, *Franciscea calycina*, *Hedera macrostegia*, and others, all of which were well grown, and did credit to that veteran exhibitor. Collections of fifteen also came from Mr. Rhodes and Mr. Baxendine.

In the class for twelve plants, Mr. Chilman, of Ashted House, Epsom, had the first prize. Among his specimens were a fine *Acrophyllym venosum*, and a handsome *Erica Cavendishii*.

Messrs. J. & J. Fraser, who had, among others, the orange scarlet *Leschenaultia intermedia*, and a fine plant of *Erica ventricosa coccinea minor*, came in second.

In the class for eight plants, a fine specimen of *Allamanda Schottii* was shown by Messrs Lee, and in other classes a very fine plant of the same kind was shown by Mr. Page. *Hoya bella* and *Erica ventricosa coccinea minor* were shown in fine condition by Mr. C. Smith, of Norwood Grove. Mr. Penny, of Regent's Park, Mr. Kaile, Mr. Baxendine, Mr. Green, and Messrs. Lee, were likewise exhibitors in the different classes.

Azaleas constituted of themselves a brilliant feature in the display, and, probably, no other flowering plant could have shown to such advantage at the corners where the nave and transept intersect as these. Mr. Turner's plants were magnificent, *Murrayana* and *Juliana* in particular. The others consisted of *Perryana*, *Mary*, *Alba Magna*, *Gem*, *Glory of Sunninghill*, *Magnificent*, *Criterion* (past its best), and *Optima*. For this collection he received a first prize; and he also had the second for another fine collection of ten, containing in addition to several of those already named, *Arborea purpurea*, which was literally a mass of flowers.

Mr. Turner was again first for six plants, among which were included fine specimens of *Gem*, *Extranei*, and *Admiration*.

Mr. Page, Mr. Smith (of Norwood Grove), Mr. Chilman, Messrs. Fraser, and Mr. Lavey also exhibited *Azaleas*; whilst new kinds of the same flower, most if not all of which have been already noticed in these columns, came from Mr. Turner and Messrs. Ivory & Son.

Of tall Cacti, unquestionably the finest were those of Mr. Green, consisting of splendid flowering specimens of different *Epiphyllums*; and a very good exhibition of the same class of plants came from Mr. Waters Sydenham.

In Cape Heaths, magnificent specimens were exhibited by Messrs. Jackson & Son, of Kingston; those of Mr. Peed being also very fine, especially *Ventricosa magnifica*, a beautiful waxy pink. From Mr. Page came a fine plant of *Victoria Regina*; and from Mr. Young, gardener to W. Stone, Esq., Havant, and Mr. Chilman, there came also good collections. The varieties were mostly the same as those seen at the Regent's Park.

The Orchids, too, of which there was a goodly show, were, with but few exceptions, the same as those exhibited on that occasion. For a collection of sixteen, Mr. Baker, gardener to S. Bassett, Esq., Stamford Hill, took the first prize. Among his plants were a magnificent *Cattleya Mossiae*, *Anguloa Clowesii*, *Lælia cinnabarina*, and *Dendrobium macrophyllum giganteum*. Mr. Bullen again exhibited several very fine specimens, including a tub of *Orchis foliolosa*; and Mr. Peed, Mr. Page, and Mr. Woolley were also successful in taking prizes in this class. Mr. Penny had a magnificent *Lælia purpurata*, with four fine spikes *Vanda suavis*, very fine; Woolley's variety of *Sobralia superba* with three fine spikes; and *Anguloa Ruckeri*. Mr. Lovell, Nutfield, who gained a second prize for a collection of ten, had *Cattleya Mossiae*, with seven blooms of the largest size; *Dendrobium tortile*, with a profusion of flowers; and *Lælia purpurata*, which is always splendid. From Messrs. Jackson came *Phaius Wallichii*, with numerous fine spikes; and Mr. Wiggins, of Isleworth, Mr. Green, and Mr. Woolley, were also exhibitors.

Pelargoniums were large and covered with bloom. Mr. Bailey had the best; The Belle, Scarlet Floribunda, and *Desdemona* being some of the finest.

In Fancies, Mr. Turner and Mr. Shrimpton exhibited some beautiful plants, which were complete masses of bloom. Fairest of the Fair, *Delicatum*, *Clemathe*, *Ellen Beck*, *Modestum*, and *Undine* were some of the finest.

Roses in pots were exhibited by Mr. W. Paul and Messrs. Lane and Son, who had splendid plants of *Lælia*, *Charles Lawson*, *Paul Perras*, *Comtesse Mole*, *Baronne Prevost*, and *Souvenir d'un Ami*, the latter from Messrs. Lane being a stately specimen loaded with bloom. Messrs. Paul & Son likewise exhibited, receiving a third prize. Mr. Turner and Mr. W. Paul had, besides, excellent plants in eight-inch pots. Cut Roses were in great abundance and beauty, ten boxes coming from Messrs. Paul & Son, and eight from Mr. W. Paul.

Calceolarias were exhibited in great perfection by Mr. James, of Isleworth, also Mr. Reid and some others; and *Pansies* by Messrs. Downie, Laird & Laing, Hooper, Shenton, Tomkins, and James. *Verbenas* came from Mr. Treen, of Rugby, and Messrs. Perkins, of Coventry; *Tulips* from Mr. Hunt, of High Wycombe, and Mr. Turner.

Of other objects, Mr. Williams, of Holloway, had in a collection of fine-foliaged plants a noble *Gleichenia flabellata*, a beautiful plant of *G. dicarpa*, and a very fine *Cyathea excelsa*; and Mr. Hutt, gardener to Miss Burdett Coutts, brought a magnificent specimen of *Cibotium Schiedeii*, *Latania borbonica major*, and *Rhopala de Jonghii* being also very fine.

Corypha australis, from Mr. Young, of Highgate, was immense; *Cycas revoluta*, very handsome; and he had also a large *Hippomane spinosa*. *Cibotium princeps*, and *Cordylina indivisa* from Messrs. Lee, were also remarkable.

Exotic Ferns came from Mr. Lavey; British Ferns from Messrs. Ivory; and some nice pans of *Lycopods* from Mr. Fox.

The pretty variegated *Lonicera reticulata* grown in the open air, came from Mr. Shenton, of Hendon; seedling *Pelargoniums* from Mr. Hoyle; and there were also several pretty arrangements of flowers in baskets, and for the dinner-table.

FRUIT.

Fruit at this early period of the season could hardly be expected in great quantity, but what there was, was good.

Of Black Hamburg Grapes, several excellent bunches and baskets were shown, the best three bunches coming from Mr. Hill, gardener to R. Sneyd, Esq., Keele Hall; these, though not so large as those of some exhibitors, were very compact, and the berries were large and finely coloured. Mr. Clement, of East Barnet, was second, and he had also an excellent single dish as well as a 10-lb. basket, and large bunches of *Black Prince*.

Mr. Frost, of Preston Hall, had a second prize for a fine basket, but the berries were not so well coloured; and Mr. Turnbull of Blenheim, Mr. Monro, and some others had also very good exhibitions of the same variety.

Of the Muscat of Alexandria, large bunches were shown by Mr. Horwood, and for the season the berries were very well coloured indeed. These well deserved the first prize that was

awarded them. The basket of the same variety from the same exhibitor was equally good. Three good bunches of the Grizzly Frontignan came from Mr. Henderson, of Coleorton Hall.

Pines were very good. A Black Prince weighing 8½ lbs., came from Mr. Cox, gardener to A. Royd, Esq.; and one nearly as large from Mr. Roger, of Taplow, both being handsome fruits. Good-sized Queens came from Mr. Barnes, of Bicton, and others. Altogether there were twenty-three fruit shown.

Violette Hâtive Peaches from Mr. Evans, and Royal George from Mr. Henderson, of Trentham, were well ripened and received first and second prizes. The Violette Hâtive Nectarines from Mr. Henderson, were also excellent.

Of Cherries, the Bigarreau Napoléon and Elton were both fine, especially the former. Mr. Tillery had Black Tartarian, well ripened; besides which there were several good dishes of May Duke and other kinds. Magnificent fruit of Sir C. Napier were shown by Mr. R. Smith, of Twickenham; British Queen, large and fine, by Mr. Tillery, the former exhibitor having also Sir C. Napier, Empress Eugénie, and British Queen; and Mr. Turner, of Slough, President, Oscar, and Sir C. Napier; but Mr. Smith's exhibition was the finest.

Several good Green and Scarlet-fleshed Melons were shown; also, Vines and Strawberries in pots, Figs, and two large and handsome Cucumbers, one of them measuring 30 inches long, but the name was indistinctly written.

GARDENIA CULTURE.

MUCH as has already been written and rewritten about this, which is, I think, the most lovely exotic evergreen we possess, yet I am not without hope that I may be excused for again referring to it.

I commence by planting strong healthy cuttings of Fortuni, florida, radicans major, radicans, and citriodora. It may be, some of the others would succeed equally well, though I have ever been cautious of varying the general stove treatment as concerns them. The cuttings struck, or nice young plants procured, their whole first season's growth should be made upon a stage in the stove; never giving a larger pot than a 48 the first year, pinching off any leading ill-placed shoots, giving occasional waterings with not too strong manure water, and not allowing any flowers to expand if any should show.

I will now suppose the plants to be beginning to grow in the March of the succeeding year. Let them make their first start in the pots (48's) of last year; when the shoots are showing the third pair of leaves pinch all back to four leaves each, and when they are about breaking afresh from the young shoots repot them, putting them into large 32's, carefully picking out as much of the old soil as is possible without injuring the ball generally or the roots; giving no manure water until you see that the roots are getting thick round the edge of the soil in the pot, when a little—but only a little—weak manure water may be given.

The chief requisite in the autumn is a profusion of healthy short-jointed wood. To obtain this, should your plants do well, you will have to pinch back any leading shoots to four leaves during the season. There need be no fear of pinching or even cutting back, so long as the knife is kept away from all but the growth of the current year.

Towards October avoid giving any but clear water, and place the plants more in the sun.

To ripen the wood gradually give the plants more sun, less water, and keep around them a drier atmosphere, reducing the temperature gradually as the days decrease in length, leaving it during midwinter at from 45° to 50°. If at times with a dryish atmosphere they are in a temperature of even 40° it will in no way injure them.

About March, as the light and heat increase, they will show signs of active growth, and then any loose soil upon the surface should be removed, and some good fresh soil be used for surfacing. Give plenty of liquid manure (strong now), and you may expect from eight to a dozen flowers, and these fine for the size and age of the plants. Give a nice moist growing atmosphere, and a temperature of from 60° to 70°. When they have finished flowering give another small shift into a 24 or 16-sized pot, and proceed again as above. I object to large shifts with excessive heat, as tending to produce large growths and but few flowers, besides taking up so much room.

With the above treatment the plants in the 16-pots might

produce some twenty-four flowers upon a surface of about 1½ foot in diameter upon a Fortuni or florida; more in comparison upon radicans.

There is one peculiarity about citriodora that I may mention—it is very prone to throwing up young growths from the base of the plant: these, if not pinched back when a few inches high, not pinching them out altogether but checking them, will at times so monopolise the sap of the plant as to cause all the old wood to wither and die. It would be as well, I feel convinced, to cut out all eyes below the surface before the cutting is placed in the cutting-pot.—W. EARLEY, *Digswell*.

MR. BULL'S PLANT ESTABLISHMENT AT CHELSEA.

MR. BULL is so well known as an exhibitor of valuable novelties at the metropolitan shows, that some notes taken on a recent visit to his establishment may not be unacceptable; at the same time it must be observed that his collection is so large that any notice of it in the limited space at our command must be far from complete.

It is to new and rare plants that Mr. Bull more particularly devotes his attention, and that his stock is most extensive may be judged from the fact that it occupies fourteen large houses, including seven Geranium-houses, one of which is 100 feet long.

On entering from the King's Road by the glass dome, we come into the first conservatory, which is gay with Azaleas and other flowering plants, relieved by the plentiful introduction of Australian Ferns, and the handsome fern-like Grevillea robusta, which forms an appropriate companion plant to these; besides which there are Orange trees both in flower and fruit, and one of the finest plants in the country of the new Araucaria Cookii.

On each side of this conservatory are wings, one occupied by the offices, the other by ornamental stands for drawing-rooms, filled with pretty variegated plants, as Caladiums, Maiden-hair Ferns, Begonias, the variegated Cyperus, Aphelandra Leopoldi, &c. There are also a number of Fern-cases of different patterns, under two of which were fine specimens of the Killarney Fern, and the beautiful New Zealand Todea pellucida.

The winter garden, an extensive space covered with a lofty span-roof, is the next house; and immediately facing its entrance is a majestic tree Fern, Cyathea serra, 25 feet high, whilst elsewhere are variegated Aloes and Yuccas, Grevilleas, Acacias, Dracenas, Palms, &c., giving the house an exotic appearance; and no one can fail to observe the Norfolk Island Pine, one of which could not measure less than 20 feet in height, and there are others nearly as tall.

Another remarkable object was a noble Cyathea medullaris, the ebony-like stems of which have a striking appearance. This with its congener C. dealbata is admirably adapted for conservatories. There were also a very handsome Cycas revoluta, which from its beautiful plumage-like foliage is always effective; Gleichenia flabellata, 5 feet high, and nearly as much through; Indian Azaleas, some of them 8 to 10 feet high; Dracena australis, between 11 and 12 feet high; Yucca aloifolia variegata, standing about 6 feet high in slate tubs; a lot of standard Bays with very symmetrical heads; also Laurustinuses, the same as are employed at the Horticultural Gardens at Kensington; yellow Rhododendrons, and miscellaneous flowering plants; and Acer negundo variegata, which from its pretty white variegation is employed as a relief to the green foliage.

To effect shade in this large structure, Vines cover the roof and festoon the columns supporting it, and are likewise trained over arched trellises at the sides. Mr. Bull states that he obtains excellent crops, and notwithstanding the general impression that Grapes and plants cannot be grown together, his experience has shown that in large houses at least, both can be successfully cultivated. The roof being very light, and presenting no adequate support for a ladder, there is a platform running on a railway down the centre of the house, so as to permit of the crops being gathered, and training, &c., performed.

On the right and left of the winter garden are stoves 70 feet long full of the new plants, for which Mr. Bull has made himself celebrated, one of them being filled with fine-foliaged plants, and having as a whole a very ornamental effect. Among the inmates of these structures were the extremely rare Madagascar Silver Palm, Areca dealbata, the gracefully arching foliage of which is silvery on the under side; a new Dieffenbachia, from Brazil; the formidable prickly Hippomane longifolia, the hand-

some variegated-leaved *Musa vittata*; *Anthurium leuconeurum*, from South America, with deep green caladium-like leaves with conspicuous white veins; a new species of the same genus also from South America; and those splendid fine-foliated plants *Alocasia metallica* and *macrorhiza variegata*, the lustrous metallic leaves of which form so important a feature in a collection of fine-foliated plants. *Thrinax elegans* is a very ornamental miniature Palm for drawing-room decoration, for which purpose its dwarf habit of growth peculiarly recommends it. *Echites argyræa* with dark green leaves and silvery veins will, to all appearance, form a desirable addition to ornamental-foliated climbers, of which there is a great paucity at present, but what like the flowers are is as yet unknown.

Of new *Caladiums* there was an abundance, and of these mirabile, regale, *Cannaerti*, *Devosianum*, *Van den Hecken*, and *Thelemanni*, with the fine Bornean species, *Lowii*, were some of the best.

Of other fine-foliated plants *Dracæna ferrea variegata* had leaves remarkable for their brilliant crimson. We also saw a new *Justicia* with beautifully variegated leaves. *Cyperus alternifolius variegatus*, one of the most effective of variegated plants, is here kept in a perfectly variegated condition by potting it in pure river sand, and affording a liberal supply of water. This is a secret worth knowing, as, in many instances, probably from being grown in too rich a soil, the plant reverts in a great measure to its original green form. Besides these many other very ornamental plants might be enumerated, such as *Latania rubra* and *Verschaffeltii*, *Cupania Pindaiba*, &c., and we must not omit to mention *Ouvirandra fenestralis*, the Madagascar Lace Plant, which was growing in a tank in one of the stoves, the leaves floating in glass bowls through which they could be readily seen, and according to their development between 1 foot and 1½ foot long, including the stalk. The extremely pretty *Clorodendron Thomsonæ*, with its white bracts contrasting with the vermilion petals, likewise formed an attractive object.

Medicinal and official plants are grown in considerable quantity; and among such might be seen the Bitter Cassia, Peppers of various kinds, Cubebs, Balsam of Peru, Coffee and Tea plants, Cinnamon, the violet-coloured Sugar-cane (*Saccharum officinarum violaceum*), &c.

In the Orchid department was *Pogonia discolor* from Java, which, with its olive-green leaf abundantly covered with reddish-golden hairs, was a great object of attraction at the last spring show at Regent's Park; and there were many pretty *Anæctochilus*, such as *Dayii*, and *argyræa* with its green and silver leaves. Fine specimens of the Fox-brush *Erides Fieldingii* and some others of the same family were rooting with extraordinary freedom in cocoa-nut refuse, and seemed to be luxuriating in it; and there were besides many other species of the same genus, such as *Larpenæ*, *Schroederi*, *Lobbi*, as well as the new *Cypripediums* *Stonei*, *Hookeri* with its prettily marbled foliage; the rare *Lowii*; *Dendrobium lituiflorum*, which recently brought such high prices at Stevens's; *Vanda Batemani*, &c.; together with an abundance of well-known species which it would be tedious to enumerate.

To *Begonias* one large house is almost entirely devoted, in which, besides several hundred seedlings, embracing an endless variety of variously-marked kinds, there were assembled numbers of named varieties—of which *Secrétaire Morren*, *Adolphe Pollack*, *Frederic Seismeyer*, *Helena Uhder*, *Dædalea*, *imperialis*, *imperialis smaragdina* and *longipila*, are some of the newest and best.

In the same house with the *Begonias* was a magnificent specimen of *Gleichenia dicarpa*, forming a beautiful mass 6 or 7 feet high, and probably as much in diameter. And in other houses were *Cibotium* princeps, equally remarkable; the new Golden Maiden-hair Fern from Lima, *Adiantum chrysophyllum*; *Adiantum Feei*, a handsome *gleichenia*-like species; *Laucheana*, the best of all the Golden *Gymnogrammas*; and the pretty tasselled *Wetenhalliana*; also *Asplenium flabellulatum* and *racchirhina*, both of which are very distinct and elegant species, the former from Mexico, the latter from Brazil. Besides the above there were numbers of variegated, including the remarkable *Pteris nemoralis variegata*, which is intermediate between *argyræa* and *tricolor*. In addition to these may be noticed several new hardy Ferns, as *Athyrium Filix-femina sagittatum*, a very pretty form of this species, which had a first-class certificate at the last meeting of the Floral Committee; *Osmunda regalis cristata*; and the handsome Japanese Ferns, *Lastrea opaca* and *Woodwardia orientalis*.

In the greenhouse department, besides the plants already

referred to in noticing the winter garden, many others deserve mention—such as *Rhynchosia albo-nitens*, a very ornamental climber with bright green leaves irregularly variegated with white, and having violet mauve flowers. *Yucca lutea-lineata* and *Y. alba-spica*, the last a very rare and peculiar plant, the narrow leaves being edged with white filaments. *Stokesii* is another variegated form of the same tribe. To these it may be added there were some handsome specimens of *Von Siebold's* *Chamærops excelsa*, and *Araucarias* *Bidwilli*, and *Cunninghami glauca*, the last a very desirable novelty.

To *Azaleas* one house is entirely devoted, and it contains many new varieties; one of these named *William Bull* is just being sent out. Its flowers are of the largest size and of unusual substance, in colour dark crimson shaded with violet on the upper segments. Waxwork, with large flowers, white blotched with purple; and *Fairy*, flesh spotted with crimson and edged with white, are also very fine; and to these may be added *Dieudonné Spæ*, *Madame A. Verschaffelt*, *Hortense Vervaene*, and *President Clæyes*.

The *Pelargonium*-houses are filled with a multitude of seedlings as well as named varieties. The following are a few of the best in the different classes. Of spotted kinds—*Theophraste*, quite new in colour, of a rich fiery red shaded with violet to the centre, light throat; *Gloire de Petit Bicetre*, also a new colour, dark crimson violet centre and spotted with maroon; *Junon*, International, *Fireball*, *Achille*, and *Viceroy of Egypt*. In *Fancies*—*Lovely*, *Bertha*, *Charm*, and *Lady Dorothy Nevill*; and in the *Zonale* section—*Beauty*, *Enchantress*, *Lucilla*, *Transcendent*, *Bonnie Dundee*, *Alfred*, and *Rosamond*. Conspicuous among the variegated kinds was *Queen of Queens*, which combines an excellent pure white variegation, with a profusion of scarlet flowers. This variety is well worthy of cultivation, and we understand that a bed of it has lately been supplied to the royal gardens.

Petunias have a house devoted to themselves, which is crowded with the splendid varieties which Mr. Bull sends out, of which *Captivation* and *President* are particularly fine, and *Lady Maria Scott*, *Beauty*, *Adeline*, *Vernon*, *Silver Spot*, *Ensign*, *Startler*, and *Marmion* are also of great merit, as well as *Charmer*, a crimson and white double.

The new *Mimulus*es form of themselves a very interesting feature. These are the result of a cross between the *Chilian* species *cupreus* and *Gaiety*, a large-flowering sort. The blossoms are about 2 inches across, and present an infinite variety of coppery red markings—blotches, belts, or specks—on a yellow ground, and of yellow specks or blotches on a dark ground. Apart from their extreme beauty, they possess the merit of being of dwarf habit; and altogether they may be regarded as constituting a valuable acquisition to our gardens. In one house there are hundreds of these *Mimulus*es, and they are likely to continue in flower for a long time.

Mr. Bull is now becoming well known for the new *Fuchsias* and *Pentstemons* which he annually sends out, and of these, as well as *Gloxinias*, there are extensive collections; but space will not permit us to do more than mention them, as well as many interesting Japanese plants, such as the beautiful-foliated *Loniceræ reticulata*, figured in the *Florist* and *Pomologist* of September last, the *Umbrella Pine*, *Retinospora obtusa*, *Bambusa variegata*, several handsome variegated *Euryas* and *Euonymuses*, the pretty *Serissa foetida variegata* which Mr. Bull received from Japan through Dr. Siebold, and the plain-leaved female *Aucuba*.

ORCHARD-HOUSES.

OWING to causes unnecessary to explain, I have been prevented replying to Mr. Rivers' kind invitation to my visiting his nursery at Sawbridgeworth. I fear, also, I cannot do myself the honour of inspecting his orchard-houses and their contents at the present time, but it is possible I may do so in August. For many reasons I prefer the latter time, not the least perhaps is, that it is a less busy period at home. I, therefore, thus publicly thank Mr. Rivers for his courtesy; and although I am unable at the present time to accept his invitation, and may also be prevented at the later period mentioned, I hope, nevertheless, to be able at some time to see his collection of trees in pots, and their modes of growth, and will strain a point to do so the present season. I, however, expect to hear more about orchard-house fruits from other quarters, and the subject seems to be warmly taken up by other writers in THE JOURNAL OF HORTICULTURE. The coming metropolitan and other shows

socket end of the knife a crane neck is attached, rising not perpendicularly but obliquely 1 inch from the blade, as shown at B, and, entering the shaft, is covered over there for security, with an iron ferule of $3\frac{1}{2}$ inches in length. The handle C is made of well-seasoned deal so as to be light, is 8 feet long, three-quarters of an inch in diameter where the socket of the blade is fixed, and $1\frac{1}{2}$ inch in diameter at the extreme end. With the crane neck placed as described, when the lower side of the knife rests level on the ground, the extreme end of the handle will be about $3\frac{1}{2}$ feet perpendicular from the ground. When the man taking the handle in both hands, the end just resting against his side, sweeps the blade right and left of him, he will clear the lawn of daisies as he marches along for a width of 15 feet easily, and with much less trouble and toil than he would clear as many inches with the lumbering daisy-rakes. Of course, the knife merely decapitates the sweet, modest, wee things, that would be beautiful anywhere else than on the green lawn; but if the sun shines the daisies will soon be shrivelled up, and unseen and forgotten, like many other things that are good and beautiful.

AMMONIACAL LIQUOR AND OTHER GAS REFUSE AS MANURES.

I KNOW you will be glad to learn that I read and practised from Mr. Johnson's pamphlet on the refuse from gasworks; but as far as my experience goes 200 gallons, as there recommended, is too much to apply at once to an acre. I find that 50 gallons do better; and if you contrast the strength of guano with that of gas liquor, it is manifest that 600 lbs. of guano will introduce about 50 lbs. of ammonia to the ground, and 200 gallons of the liquor will give 200 lbs. of ammonia. I am also using the lime and the tar of the gasworks, and I find them of great benefit.

To give an idea of the value of the tar, I may state that I manured an acre of ground with farmyard manure of a good description and another acre with the tar, and I had five cocks of hay from the farmyard manure, and seven cocks from the tar.—C. REYNOLDS, *Parish Priest of Kildalkey, Ireland.*

[As we never knew any gas liquor so rich in ammonia as that specified by Mr. Reynolds, we wrote to him expressive of our doubts as to his accuracy on that point. He has not cleared away our doubt, but his reply contains some useful information. The following are extracts:—

"I have a vessel which holds 30 gallons, and apply it to an acre with the best results. I mean 30 gallons of the liquor as it comes from the gashouse, diluted with as much water as may seem needful. From my observations I am certain that 1 gallon in winter contains as much ammonia as 2 gallons do in summer. I never found the same observations in any book that has fallen into my hands.

"With regard to fixing ammonia, Liebig, in his 'Agricultural Chemistry,' page 180, says, 'If we fix it, if we deprive it of its volatility, we increase its action twofold.' The method used by Liebig to fix the ammonia is to mix the liquor with gypsum; but it can be done as well by spreading it on the ground in winter, as the rain washes it into the ground. In summer the heat of the sun makes it volatile."]

GEOMETRY APPLICABLE TO GARDENING.

(Continued from page 314.)

LINES.

Side-lines are those which encompass any sort of figure, be it either a square or a polygon, as does A B C D, fig. 1.

A *diagonal line* is that which passes through the very centre

of a figure, and which begins and ends at two opposite angles, as E F, fig. 2, and G H, fig. 3.

Fig. 4.

Fig. 5.

The *diameter* usually signifies a line that passes through and touches the centre of a circle or oval, as does the line I K, in fig. 4, and L M, in figs. 5 and 6. In an oval there are two, called the transverse and conjugate diameters. L M is the transverse se.

Fig. 7.

Fig. 6.

The *chord* or *subtense line* is a line that cuts off only a smaller part of a circle from a greater, or is, more plainly, like the string of a bow, which is part of a circle, as is the line N O, fig. 7, the bow of which is N O P, and the remaining part of the circle is R, fig. 10.

Fig. 8.

Fig. 9.

A *tangent line* is that which touches any figure (whether circular or polygonal) without dividing it, and without being able to divide it, although it were prolonged never so far, as are the lines S T, in figs. 8, 9.

A *secant line* is that which divides or crosses any circle, oval, or polygonal figure, the said oval or other figure remaining whole, and is plainly demonstrable by the lines T U, in figs. 8, 9. (To be continued.)

WHAT IS AN ORCHARD-HOUSE, AND WHAT SHOULD BE EXPECTED FROM IT?

WE have much argument on either side as to the merits and demerits of "orchard-house culture," but no one seems to have attempted anything like a judicial summing-up of the question. Let me, however feebly, attempt this. The first question is, What is orchard-house culture? From Mr. Rivers' exposition we may define it as "the growth of fruits in a cold house, and that not in, but through, pots." The house must be cold, or it is a forcing-house; and the plants must grow *through* the pots, or the question resolves itself into a contention between the advantages of culture in pots in a cold house, and culture in pots in a hothouse.

From the evidence it appears that trees planted out in a cold house, will, in their season, yield fruits, many large and good-flavoured, which if inferior to those planted out in hothouses in size and earliness, are superior to them in cheapness.

But it would seem that many amateurs have attempted the cultivation of fruit trees in pots in cold houses, and have failed; and thereupon the cultivators in forcing-houses (who are mostly professional gardeners)—first telling us that even with the aid of their expensive appliances and skilled labour, they have found culture in pots attended with 100 per cent. more trouble, and a diminution of 50 per cent. in size—proceed to draw comparisons between their planted-out trees in hothouses, and the trees in pots in cold houses. Now, such a comparison as this is inadmis-

sible. The match should be between skilled gardener and skilled gardener, between planted-out trees in a hothouse and planted-out trees in a cold one, between pot trees in the one and pot trees in the other. It should be borne in mind that the orchard-house faction numbers in its ranks but few skilled gardeners, while the other side counts many. Yet Messrs. Rivers and Pearson offer to show their planted-out trees and pot trees against like trees in a hothouse; but nowhere have they offered to show trees in pots against trees planted out.

It is to be observed, that when an orchard-house cultivator boasts of fruit grown *through* pots, his evidence is met by the reply, "You cannot call that pot-culture;" as if culture in pots were part of the orchard-house system, which it is not. There are only two questions to be answered. First, Are cold houses properly used for fruit-culture, worthy of a place in our gardens? Second, Which is the proper mode of culture in them—planting out, growing through pots, or growing in pots?

Answers to these questions may do us some good, which a wordy war as to whether skilled gardeners with planted-out trees can grow better and more fruit than amateurs with trees in pots is not likely to do.—G. H.

SMALL VINERY HEATED BY DUNG.

I PURPOSE carrying out a plan I read of many years ago, I believe in London, of erecting a small house heated by a dung-pit; but I have never seen one, and do not find any notice of it in the modern books I have had an opportunity of reading, and I am apprehensive that some practical difficulty may have developed itself, and prevented the suggestion from being usefully carried out. You can tell me in a line whether this be so. I propose to have a house 10 feet by 7 inside, with 3 feet along the front occupied by a chamber for dung 3 feet high; the dung to be filled in from the outside, and shut in closely by well-fitted doors, and the chamber formed of solid wall, but open at the top. Over this chamber some durable rails will sustain a bed of brushwood, or some such materials, upon which a bed of mould is to be placed, so that bottom heat will be applied to that bed of mould, and no other egress for the heat of the dung than into that bed will exist. The advantages I look for are—the rotting my dung out of sight, using the heat entirely, and the facility of putting in and out of sight all rotting materials, and avoiding loss from evaporation, and I suppose the dung may be put in fresh from the stable; but as to that I am not sure, nor do I quite know what depth of mould I should have. Upon that bed I should hope to raise anything wanted for transplanting, besides Cucumbers trained to the glass in front above the bed, and perhaps Melons.

This small house would be put against a south fence 6 feet high, from the top of which fence I purpose to have glass at an angle of 34°, to join the front sash. This slope will have the sun constantly from sunrise to sunset; and as I shall have 4 feet behind my dung-chamber, I suppose I may make that space a bed for a good Vine to be planted in the centre of the back, and have the benefit of the glass slope; and I suppose that such a little affair will never have too much heat to have the Vine roots inside, and thus avoid some risks I read of in your publications.—H.

[We think we know what sort of a house you mean—something of a span or a hipped-roof; but a few simple lines would have made us more sure. As the chamber for dung is to be 3 feet deep in front, we presume the front altogether will be some 5 or 6 feet in height. Now, having settled these matters, we can assure you that if you do not mind the trouble of turning the dung over in the chamber, and adding fresh often, you will be able to do many things with such a house, more especially if you do not ask it to do too much before March or so. We would not advise you, however, to have rails of wood, or brushwood to cover your pit, because in the first place you may have too much moist heat when you want dry heat, too much bottom heat when you would like some top heat, and you might have injurious steams passing through your soil and destroying the effects of all your labour, if there should be such a thing as a crack or a crevice in your soil. If such a house is to be so managed with dung, it is of importance that fresh dung, droppings, &c., from the stables should be used with safety, and for this purpose a close top to the pit either of plate iron or slate, then flagstone, &c., would be necessary. In building the front wall, therefore, at the suitable height, a ledge of bricks from 2 to

3 inches wide should be left out all the way along to receive this covering of the pit, whilst the other side of the pit will receive the other side of the covering, and the wall being carried above it as a curb to the pit, will keep the covering firm and secure. The front wall will require to be nine-inch work, and the openings for the dung may be arched or otherwise; but if economy in heating is a matter of importance, if the front wall is hollow nine-inch work, but tied together, there will be less escape of the heat of the dung to the outside atmosphere. The inner wall of the pit should be single brick on bed, with a pier in the middle, and these bricks should be laid in cement, to prevent any steam from the dung getting into the house. If two or three good-sized slates 1 inch thick were let into this inner wall, the heat would radiate from them sooner than from the bricks.

Suppose that a covering of slate over the pit is used, and firmly and securely jointed with cement, the heat from the dung will be as dry almost as if it came from a flue or a steam-pipe, and no noxious effluvia will be given off. As already hinted, heat will be given off from the inside wall, but the chief amount of heat will rise to the flooring above the pit, and when the pit is pretty well filled with dung containing a fair proportion of horse-droppings, the covering of the pit will get very hot indeed, and it is of importance that we can have that heat damp or dry, and allow it to go to the roots of plants, or keep it from them, just as we like. For example: You wish to keep some plants of a half-hardy character in winter, with, perhaps, the help of a little covering, well damp will be the great enemy. No water should be spilled in the house; the plants over the slate should be 1 foot from it, and be moved when watered, and the slate covering kept as dry as possible.

Again, you wish to strike cuttings in this pit in March. The simplest mode would be to cover the slate with some 6 inches of sand, and plunge the pots in it, easing them up if they get too hot, and keeping the sand moist or dry, as you wished a moist or a dry heat. And, once more, you propose to plant out and grow Cucumbers. Well, place from 4 to 6 inches of open rubble on the slate, covered with an inch of clean-washed pebbly gravel. Place four or five three-inch drain-tile pipes upright at the back, their bottom ends communicating with this rough boulder-chamber of rubble, and place your soil above the rubble. These pipes are to be stopped at their upper end with plugs. The rubble will prevent the roots being scorched. When bottom heat is wanted, keep the plugs in. In a dull day, when more top heat is wanted, take them out. If a sunny day comes, and there is a deficiency of bottom heat, put the plugs in, and so on. The rubble might be dispensed with, if there was a second rough flooring, such as common slate, supported on pieces of brick 2 or 3 inches above the first and secure one, with the upright pipes opening into this shallow chamber. In either case, when a moist heat was wanted, a little water poured down the drain-pipes would supply moist vapour either for roots or branches. Even for cuttings we would like this plan better than placing sand, &c., at once on the covering of the pit.

We are thus particular to please our correspondent, but such a mode of heating could not be recommended, except where the good dung cost nothing, and the labour spent in securing the heat that would have otherwise been lost in decomposition is considered to be well paid in the rotten dung thus obtained for many purposes, all the richer from having been but little exposed to air, though getting enough of this to carry on the process of decomposition.

If you used Vines at all in such a small house, we would recommend two, the Black Hamburgh, and the white Royal Muscadine. They will do well in the four-foot border, if that be well made, and if the pit were deeper than the top of the border, the roots would not at all dislike the heat.—R. F.]

A GARDENER'S LOVE LETTER.

[THE following epistle is dated from "Sunflower Terrace, Primrose Hill," and is addressed—

"To M—, who in prospect I hold
To make my new garden like Eden of old."]

MY ROSE-MARY—As you are the Pink of Perfection, and the blossom of May, I wish to tell you that my Heart's-ease has been torn-up by the roots, and the Peas of my holm entirely destroyed since I began to Pine after Yew. You will perceive that I am a gardener. My name is *William Budd*. At first I was poor, but by shooting in the spring and driving a Carnation

fast, I obtained a Celery, and by a little Cabbaging I Rose to be master, though something like a Creeper, of the whole garden.

I have now the full command of the Stocks and the Mint; I can raise Ane-mone, from a Penny Royal to a Plum, and what my expenditure leaves I put in a Box for Yew. If I May, as a Cockscomb, speak of myself, I should say that I am in the flower of manhood—that I am neither a Standard nor a Dwarf, a Mushroom, nor a May-pole. My nose is of the Turnip Radish kind, and my locks hang in clusters about my Ears. I am often in the company of Rakes, and rather fond of Vine and Shrub, which my Elders reprove me for; so I had better Berry all this, and say that I have at Windsor Bean, and have some London Pride; and as I am a branch of a good Stock with a portly bearing, I well know when and where to make my Bough.

So Lett-uce act for ourselves, and fix an early day for grafting your fate with mine, which might be made a Poplar measure, but I think it had better be Privet; for Jon-quil, the lawyer, says that your old Crab of a father, who did never a Li-lack when he wanted to part us, means to take the Elm in his own hands in this matter; but if he does, and Bullace me at all, I will not be Sloe in settling his Ash, and I will be such a Thorn in his side that the day he does it shall be one of the worst Days-he ever saw.

But I must sow no seeds of discord, for I am certain that we should make a very nice Pear, and never repent. Even when we become Sage by Thyme you would be the Balm of my life, and I should be the Balsam of yours; so that people who might call us green, now would call us Evergreen hereafter. And now Sweet Peas be with you, and if he who tries at it Tares me from Yew I shall become a Melon-Cauliflower, and wither away. My tongue will always be a Scarlet Runner in your praise; for I have planted my Hops in Yew, and now I only live for the Thyme when I may hear from your own Tu-lips that I am your Sweet William and not your—WEEPING WILL-O.

NEW YORK FLORISTS AND FLOWERS.

GREAT progress has been made both in the science and practice of plant growing and selling by the florists of New York since the days when quaint, but withal shrewd, Lawrie Todd adopted the system of painting his flower-pots to attract customers' attention, and his inaugurating a taste which now requires a great deal both of energy and capital to supply; but the plants being now of themselves sufficiently attractive, the painted pots can very well be dispensed with. Although many of the florists, thorough-going business men though they be, are not gardeners by profession as defined by Loudon in his "Encyclopædia of Gardening," still we have such men as Mr. Robert Reid, who has often officiated as a judge of plants at Chiswick in its palmiest days; Mr. Buchanan, a skilful and successful hybridiser; and Mr. Peter Henderson, of Jersey City, whose practice of growing fine saleable plants in the smallest possible pots I have never seen excelled; and all these are professional gardeners who would do honour to horticulture in any country. Glenny's "Properties of Plants and Flowers" is a work almost ignored here, the property most in request being abundance of bloom, a large and fast-increasing business being done with cut flowers; and this winter the supply has never been equal to the demand.

Bouquets are arranged most artistically, and with great diversity of taste; indeed I have never seen them excelled even in Covent Garden. Rustic hanging-baskets and stands for parlour or drawing-room are now in great request, Ferns, Lycopods, creepers in variety, and many adaptable variegated and fine-foliaged plants being used with great advantage.

The Camellia is deservedly a general favourite, and is both extensively and well grown, the retentive yellow loam which abounds here being well adapted to its culture; but I have not yet seen anything to be compared to the handsome plant of reticulata that Mr. Blair (now of Shrubland Park) had at Bank Grove with its 2000 expanded blooms. The flowers are not cut, but very adroitly twisted off without any damage to the plants, then neatly "fixed up" for either bouquets or baskets.

Roses are to be found in every collection, and fully maintain their position as the queen of flowers; for though not blest here with a Queen Victoria, still we have our Queens of Beauty and of Flowers, and well represented too.

Violets are grown by the thousand, and do remarkably well. The strongest runners are selected and planted out in May, by September these make fine strong plants; they are then lifted,

and planted in cold frames prepared for their reception, and by careful attention to protection and ventilation supply an abundance of dark blue highly-scented flowers from November to April, each flower as large as a penny-piece. As an instance of their fertility, one florist picked 18,000 for last New Year's-day: these would sell readily at from 75 cents to 1 dollar per 100. On the 3rd of April I picked 3700 from twelve hand-lights, and could easily have picked 4000.

Stevia and Eupatorium are indispensable for white flowers, and are real boons to the florists. The quantity of flowers on the Bignonia venusta, trained to the rafters of a greenhouse and judiciously managed, almost exceeds belief. Tuberose flower very freely, and are most desirable fall flowers. Gladioli have been found to be admirably suited to this climate, and several of the florists have now very extensive collections.

Many of the popular names for plants are rather perplexing. Soon after coming here I was asked for my "Lady Washingtons," and had to confess my ignorance of what class of plants were known under that most honourable name. From this dilemma I was quickly relieved on coming to Pelargoniums; but finding on further investigation that Pansies were popularly known as "Johnny Jumpers," I had to commence and revise my stock of synonymes.—DAVID FOULIS, *Astoria, Long Island, New York.*

VINE-BORDER COVERED WITH FERMENTING DUNG.

My Vine-border is covered with about 2 feet in depth of hot dung, and wood shutters are placed on the top. I have been advised to remove it entirely, and place nothing on except a little litter and the wood shutters. My Muscats the last two years have shanked very much. This year I have noticed a small black speck on the side of the berry, which gradually increases till the berry is decayed. I have no border inside, and that outside is 2 feet deep, and well made. I examined the roots in the winter, and they were in a strong healthy condition. —A YOUNG BEGINNER.

[You may injure the roots if the manure was too hot. If not too hot now we would allow it to remain until the middle of June, as in this weather the border will lose more heat than it will gain from the sun. Then it would be advisable to cover with litter in cold weather—say at night, and remove the litter in sunshine and fine weather until July. We cannot see the philosophy of putting litter on now and the boards above it, as the latter would intercept the sun's rays. Give plenty of air inside.]

OLD VINES VIGOROUS BUT UNFRUITFUL.

[The following refers to our notes on the subject at page 340.]

"I will give you the particulars as nearly as I can remember. In the month of February I began fires, and made a hotbed at the same time with manure, just as it was brought from the stables. The bed consequently was very hot, and the heat very rank. If I remember right, the bed was too close to the Vines; at all events the Vines did not break, and they seemed quite dead. I cut them down to the bottom; they then broke and made capital wood, which seemed quite ripe to the top.

"The leaves I sent last week only belonged to the weak Vine, since then a weak one close to the other has something of the same coming. As soon as I received your paper, I cut the first piece away, and only discovered the one alluded to this morning. I have not given fire heat, and when the sun is out I give air.—H. H. C."

[Our surmises we find have been pretty correct. We would not have given fire heat along with the rank manure. We would have allowed that to act upon the Vines alone for the first fortnight or three weeks, and by that time the heap would be getting sweet. The rank manure would not injure Vines in a state of rest; but if there was so much of it as would raise the house from 45° to 50° without sun, then we would give a little air, and even in the daytime we would not with sun heat let the thermometer rise above 60° or 65° for the first month. We have used manure direct from the stables as it could be got, so rank that we do not think the mere rankness would do the mischief; but excessive heat to unstartened Vines, or placing that steaming heat nearer than 3 feet from their stems might do the mischief. The great thing is to have all the manure sweet enough for Cu-

cumbers before the Vines break. If the Vines had been forced before, it would be advisable in February to have used manure once turned before taking it to the house. We were afraid you had the mildew on the weak Vine, and now we feel pretty certain of it. The treatment you are giving is the very best to cause it to spread over the house. Wherever there is the faintest trace of it, dust the part, stems or leaves, with flowers of sulphur, and wash the walls of the house with sulphur and lime. We would also say, daub a little sulphur on the heating medium, but we do not know what it is, and the part so daubed should not be more than 160°; and, therefore, you might easily have it too hot. The means for eradicating the mildew and securing a crop next season will thenceforward be identical—and that is, not refraining from fire heat, and giving air only when the sun shines; but giving fire heat so as to prevent the atmosphere falling much below 60° without sun, and to permit of air being given every day, and if a little at night too all the better. The fact is, that having started the Vines into growth, then allowing them just to take their chance is the best plan for getting no crop next season.—R. F.]

CLARKE'S PATENT SCYTHE.

THIS simple, handsome, and convenient scythe was sent to us for our opinion, which we now express; but to have it thoroughly tested we sent it to Mr. Cuthbert W. Johnson, and this is his evidence upon the implement:—

"Waldronhyrst, Croydon, May 19, 1863.

"I have much pleasure in bearing testimony to the great excellence of Clarke's Patent Scythe. My gardener is of opinion that no one who has tried Clarke's Scythe will be willing to go back to the old kinds.—CUTHBERT W. JOHNSON."

WORK FOR THE WEEK.

KITCHEN GARDEN.

ADVANTAGE should be taken of the present showery weather to transplant and earth-up all crops that require it, for if done when the soil about them is dry, they will not receive that benefit from rain which they otherwise would do. In pricking-out, or transplanting, particular care to be taken to press the soil close to the roots of the plants, for if left hollow and loose about them, drought will soon stop their growth, or, probably, cause them to perish. Wherever it is convenient to plant with a trowel, it is far preferable to planting with a dibber, as with the latter the roots are either left hollow, or are crushed up together and rendered nearly abortive. This is sometimes the reason why plants of the same sowing vary so much in their growth; in one case the plants are pulled up and deprived of half their roots and carelessly planted, in the other they are dug up with care, and are then transplanted and watered, and progress favourably. *Asparagus*, keep the surface of the beds free from weeds. Where the supply from the established beds is abundant, the weakest heads may now be allowed to grow, they are not so likely to keep strong buds latent, as if strong ones are allowed to run up to maturity. *Broccoli*, prick-out into nursery-beds any that are sufficiently advanced in growth. Sow a full crop of Cape and Grange's Early White. *Cabbage*, where they were planted in the autumn at a foot apart in the rows, every alternate plant should be pulled up as required for use, this will give those remaining space to attain perfection. *Cardoons*, sow a late full crop. Plant out the early crops; if they were sown in a seed-bed choose a rich piece of ground for the purpose. It will not be necessary to plant largely of the first crop, as it soon runs to seed. *Celery*, plant some of the most forward into trenches, keep it well watered in dry weather. Continue to prick out from the seed-beds for late crops. *Endive*, make a small sowing. The sowing for the main crop to be made about the middle of next month. *Dwarf Kidney Beans*, earth-up those that have been planted out, and sow again. *Lettuce*, make a sowing of two or three sorts, by such means the season of one sowing is prolonged. The Paris Cos is a very good summer sort. *Potatoes*, as soon as they appear above ground to be hoed between to loosen the earth, and to destroy weeds. *Turnips*, make a good sowing for early autumn use. Thin-out the advancing crops. *Vegetable Marrows*, plant-out this very useful vegetable on a rich piece of ground, where there is plenty of room for the plants to grow. *Sea-kale*, thin-out the buds so as not to allow them to crowd each other, and water once or twice during the summer with a weak solution of salt and water, which will

benefit the plants and dislodge snails and other vermin. Two ounces of salt to a gallon of water will be sufficient. *Trench-up* every spare part of the garden for the first plantations of winter stuff. Let it be trenched 2 feet deep in the first instance, after which give a coat of manure, and dig it in; when the plants are fit the ground will be ready for planting with Broccoli, Brussels Sprouts, Kale, &c. The former to be planted 2 feet apart each way, if fine heads are desired; the other two sorts will do well with a few inches less space. After they are planted to be protected from slugs by placing a ring of hot lime around each plant.

FLOWER GARDEN.

All annuals should be thinned-out as soon as they are above ground, for if left to grow too thickly they spoil one another, and never make half the display plants do that are allowed plenty of space, and which are grown strongly from the first. After the bedding-out is accomplished, a reserved stock should be taken in hand to receive high cultivation, in order to fill up blanks the moment they occur, either in the houses or in the beds and borders. All the best Verbenas, Fuchsias, Calceolarias (especially shrubby kinds), Petunias, &c., will be found most useful things. Attend to the staking of Pinks and Carnations as they grow, this will greatly enhance their appearance when in bloom.

FRUIT GARDEN.

Watch the first attacks of caterpillars on Gooseberry and Currant bushes, and apply dreggings of white hellebore powder when the bushes are wet with morning dew. One application will prove sufficient, if every part of the bush is properly dusted. When black fly has attacked Cherry and other wall trees, give them thorough good waterings with the engine. Use pure water for the first time, which will partially destroy the fly, then apply by the same means a good washing of soapsuds and clear soot water. If prosecuted thus, by repeated applications they will all disappear.

GREENHOUSE AND CONSERVATORY.

The young stock of hardwooded plants should be growing freely, and will now require careful attention to supply them with a warm and moist atmosphere, and with sufficient air at favourable opportunities to secure short-jointed, and compact growth. Balsams to be frequently shifted into large-sized pots placed in a gentle bottom heat near the glass, with sufficient air to prevent them from being drawn. The *Epacris* that have done blooming and are now commencing their growth to be potted, they delight in sandy heath soil. The Chinese *Azaleas* going out of bloom should have their seed-pods picked off, and such as require more pot-room to be shifted, using rich fibry peat, with a good sprinkling of silver sand. *Cinerarias* to receive plenty of air to keep the plants in a healthy state without drawing the foliage. The green fly to be kept down by tobacco smoke. When stock of a good variety is required, the sooner the plants are headed-down after blooming to within an inch of the pot the better; they will soon make side shoots, which should be carefully divided with a portion of root to each, and planted singly in a small pot, to be placed in a cold frame, and shaded from bright sunshine. The *Chrysanthemum* cuttings now in small pots to be transplanted to the open ground 15 inches row from row, and plant from plant, to be taken up in a showery day in autumn, potted, and watered, when they will not feel their moving. Cuttings of *Rollisson's Unique Pelargonium* that is generally so difficult to strike after mid-summer, will now strike freely in sandy soil in a gentle bottom heat. It is well worthy of attention, producing very large clusters of rich violet or crimson-purple blossoms. It is valuable for grouping, for vases, or for training against a wall. It requires to be freely cut back in the winter and spring to encourage lateral growth, and being luxuriant in growth and sparse of branches, it requires to be pegged to the ground when planted in beds. It will be well to bear in mind during the summer, that the shape and sturdiness of every plant will depend, in a great measure, upon frequent attention to pinching-out the points of every strong-growing shoot before it gets too long. Also, a liberal supply of good, clear liquid manure to be given occasionally—that is, once or twice a-week, according to the state of the weather, and the healthy or luxuriant growth of the plants, from which it is to be inferred that plants in a sickly state, or such as have been lately potted, will not require it. Indeed, to such it would be a positive injury. To commence with the liquid manure weak, and to increase its strength with the strength of the plants, and the increasing temperature of the summer sun.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

SLIGHTLY earthed-up Potatoes, but the forwardest out of doors will, we fear, be the second, as they were much injured by the frost of the 2nd inst. Earthed-up Cauliflowers, drawing the earth to their sides, and leaving a hollow in the centre of the ridge for future waterings if needed. Watered those in bearing that were under hand-lights. We generally place them in two or three rows, some 4 feet apart, and then when the plants are large a trench is dug out to bank them up, which then comes in for Celery. Pricked-out seedlings of Greens as time could be got and a spare piece of ground for the purpose. Broccoli has done very well this season, and even now is contending with the first Cauliflowers. Peas seem to be coming late out of doors, though when a person can have a good row in an orchard-house it makes one feel more independent. Broad or Garden Beans have done less good. They will not set well if the house is much shut up. Even for such purposes, and Strawberries a week or a fortnight earlier than out of doors, these houses are invaluable, to say nothing of salads, &c., in winter. Run the hoe among all growing crops, and especially young Onions, Carrots, Parsnips, &c., and will defer thinning much until we get a good rain; for, though thankful for what we have had, the drizzlings, though putting a little water in our tanks, have done little more than lay the dust, the ground that had previously been mowed—such as flower-beds—being still very dry, and requiring, therefore, more water when planting.

FRUIT GARDEN.

Went over Peach and Apricot trees, but not time to do more than a little to them. Syringed with soot and lime water to keep fly and caterpillar at bay. Gave extra syringing to Cherry trees and watered at the root besides, and did the same to Plums. Will thin and nip the shoots of Pears as soon as we can get at them. Went over trees in orchard-house, tied and stopped shoots in Peach-house, and slightly smoked again, as we noticed some signs of our old enemy, the brown beetle. Regulated Strawberries in the houses for the last time, and noticed a berry here and there that seemed to get hard, refuse to swell, and at last rot away, which I attributed at first to extra moisture, but which my manager thinks is caused by syringing with the sulphur water which I have several times described, and which, though of a milky appearance, leaves no mark behind it, and seems to injure nothing else. It is worth noting, however, so as to keep it from the fruit of Strawberries. Of course, they might be freely syringed before they were in bloom. Thinned Grapes, regulated and tied-in shoots of Vines. The forwardest ones have still the covering of about a foot of leaves, which keeps the border about 68°—at least at the surface. The late house, which has come earlier than I wanted, has the border fully exposed—only the surface is still cased with the thin film of tar and sawdust. We will not remove it just yet, as the soil is wet enough beneath, and the casing will throw past these cold rains. In fact, if these cold nights continue, as the Vines are so forward inside, showing the bunches, we will throw a little long litter over the border and rake it off when the sun shines, and put it on again at night; but if the weather is mild we will save ourselves the trouble. We will let the leaves on the other part alone for some weeks yet; in fact, until we are sure that the sun will throw in more heat during the day than the border will lose by radiation at night. There would be about 18 inches of leaves covered with litter at first, and that, of course, got closer together. To take advantage of the little heat given off, frames were set on the top of the leaves, and lots of things forwarded. A small part next the house has been uncovered, and a little warm water given where it was at all dry. When we move these leaves off and the film of tar, we will, most likely, cover with litter at night for a week or two. Stopped shoots and thinned shoots of Figs, and watered well, as it is advisable not to give too much water when the fruit is ripening, and the crop is a very heavy one. Potted Vines, &c.

ORNAMENTAL DEPARTMENT.

Removed faded plants and took fresh to conservatory. Will clear Azaleas of their faded flowers as soon as possible, and then place them together that they may be kept closer and be well syringed. A house, or pit, where they could get a temperature of 50° at night for a fortnight, and then a rise gradually to 60°, would cause them to make their wood quicker, and set their buds sooner. Under the shade of Vines in a rather late house would just be the place for them, if certain that there was not such a

thing as a single thrips on the plants; for, if there be, there may be no end of trouble with such insects on the Vines, as they will prefer the Vine to the Azalea. It is advisable to give them a little rest after flowering, before exciting them with extra heat. It enables the plant to recruit its energies as it were. The plants will do very well in a conservatory or a greenhouse, treated as mentioned above; but the flower-buds will not set at the points of the shoots so early, because the shoots will not be so soon formed; and the same rule will apply to all such plants as Camellias, Epacris, and, to a certain extent, to free-growing Heaths, though the latter must be hardened-off by more air at an early period.

Epacris, when done flowering, cut back, and that may be done pretty freely if the cutting is confined to the wood of last season; but older wood should rarely be cut into, as many good plants have thus been irremediably injured. These, also, when cut back, should be kept close and cool, with but little water for a fortnight or three weeks, and they, too, will succeed if kept in the warmest end of the greenhouse; but they will do better if placed in a closeish temperature of from 55° to 60°, and continued in it until the shoots are growing freely; and then the plants should be moved to a cold pit, where they can have more air admitted by degrees, and then be hardened-off by full exposure in autumn, except during drenching showers. Potted plants for houses, and also for flower garden, as they are too small for turning out—in fact, most of our strength has been directed to the flower garden, looking over herbaceous plants, pricking-out Wallflowers, and turning and preparing beds for bedding plants; and in this turning and burying sunbeams consists no small part of the success in such cold stiff soil as we have to deal with.

We feel there is something so peculiarly egotistical in speaking of arrangements, that we should not have adverted to them had not several readers and correspondents told me that the arranging of the beds, and the distance of the plants from each other, would be more interesting to many than telling about brown beetles and the planting of Cauliflowers. Now, as already stated, for various reasons, but chiefly to save time in planting and keeping right afterwards, we have resolved to adopt the most simple modes of arrangement this season. We will then just state, to please our friends, the planting of two groups of beds, close to the east side of the mansion. These beds are extremely simple and unique in their way. One group of fifteen beds is on the south side of a corridor and wide piece of pavement, and in front of the drawing-room windows; the other group of fifteen is on the north side of the corridor, and in front of the dining-room windows. We will then take one side—say the south, for both sides are alike, and planted alike. The fifteen beds are squares of 4½ feet on the side, and arranged in three lines of five beds in each line. These beds are separated from the mansion by 30 inches of pavement; from the broad gravel walk in front by a similar width, and then the beds are separated from each other by stone pannels of 14 inches in width. Every year these beds have been arranged differently.

This season they have been planted in squares—that is, a square of 18 inches has been planted in the centre of each, and that planted different from the 18 inches all round, and so that the form may be maintained with little trouble; and also that there should be little difference in the height of the beds, the tallest, if anything, next the mansion. The following figures will represent the fifteen beds in three rows, beginning next the house, and marked just as the man had them to plant by.

14	8	2	6	12
10	5	1	4	11
15	9	3	7	13

The figures are arranged in this seemingly-without-system mode, in order that the planter may see at once he is working from a centre, and that the beds shall pair with each other. The centres, 18 inches square, are generally filled with nine plants; the other 18 inches round, leaving a regular space next the pannel required according to the plants and their size, from one and a half to two dozen more—say from thirty to forty plants in a bed. The inner square of 18 inches will be the first mentioned.

1, Madame Vaucher Geranium, white, mixed with Snowflake

Verbena, in case the flowers of the Geranium should not be thick enough, bordered with Purple King Verbena.

2, Stella (Beaton's), and Golden Chain Geranium.

3, Newlii, and Cloth of Gold Geranium.

4 and 5, Scarlet Globe, and Bijou Geranium.

6 and 8, Calceolaria, stiff plants of Aurantia multiflora, and purple Heliotrope, the latter chiefly for the scent near the windows as well as the colour.

7 and 9, Calceolaria Aurea floribunda, with blue Anagallis next, and then a band of Lobelia speciosa.

10 and 11, Christine Pink Geranium, and Tropæolum elegans.

12 and 14, Boule de Feu Geranium, fringed with white Verbena, and that with Christine, a rich puce.

13, 15, Brilliant Geranium, skirted with Variegated Alyssum, and that bordered with Charwoodii Verbena—a stiff upright grower, with small purple flowers, and though one of the oldest one of the best for effectiveness, the habit being so good, and the foliage so small. The other side with the fifteen beds is planted the same, so that each group is balanced from the centre square 1, and then each group as a whole is a counterpart of the other, from which it is separated by the broad piece of pavement. Beyond the walk in front is a grass terrace, bounded by the border to which we referred last week. As we want effect soon, these squares were planted thick, and some of the Verbenas were not very large. The Geraniums were nice stiff plants showing flower; but nine plants did not do more than fill the outside lines of the eighteen-inch middle square.

But for time we would have described the planting of some ribbon-borders; but perhaps it would be as well to reiterate two or three particulars in our planting. First, most of our plants being raised from temporary beds, there is no trouble in loosening the balls, which is a necessary operation if the plants are turned out of pots which they had filled with their roots. Lifted as ours are, the rootlets are quite ready to run away into the soil of the bed. Of course the plants feel the moving the first week or so. Secondly, we have never been able to dung our beds or give them leaf mould as we would wish, or even do much as respects changing the soil; but we make amends for this by changing the crop generally every year. The beds being poor, and the soil generally rather rough, we make it a point to give every plant a handful of rich light soil to start in, and anything particular gets two or three handfuls. When we can do so with small things we place some of the prepared compost on the bed, and draw it in round the plant with the trowel or the hand as planting is going on. We seldom can afford to be so extravagant, so generally as the planter makes the hole and sets the plant in it, a little boy pitches down to him the little soil as he goes on. This compost is formed of two parts of road-drift and road-scrappings, chiefly for the ground flint they contain, though we get weeds with it. This is turned several times during winter and spring, and then sifted through an inch sieve. To this is added one part of sifted leaf mould, ditto sifted old Mushroom dung—and this is why we required to clear the Mushroom-beds out—and one part of burnt earth, clay, and charred materials, generally pretty hot, which thus makes the compost when well turned very comfortable as respects temperature. If the burnt clay, &c., do not settle the worms that may be in the leaf mould, &c., a little lime is added. This mixture is thus both light and rich, and the roots go into it at once; and thirdly, almost every plant except those pegged-down is staked and tied as soon as planted, the stakes preferred for all bedding plants being the twiggy branches of the Spruce Fir that have lain the best part of a twelvemonth. The more twigs there are on them the better. If the branches have been used as the bottom of stacks all the winter they will be nice and straight from the weight above them. These hurdles burn so beautifully that we have had to threaten the lad that attends to the mess-room fire; for when he wanted the kettle to boil he forgot about our bedding plants. We have these made into bundles from 1 foot to 2½ or 3 feet in length, according to the size of the plants to which they are applied. We have had the same twiggy sticks for a number of years; but for nice purposes they are not so effective as new ones, as the small twigs get rotten and broken off. This staking adds greatly to the labour; but in such an exposed place as this we should have things swept off without them. On last Tuesday we had some things broken and cleared off, but mostly when untied. For a month or so the sticks are rather prominent, but then the object is seen, and that gives them at least the commendation of fitness, and the beds also, if well twigged, have a certain amount of shelter. When the beds come to be at their

best the sticks are all concealed, and the shoots are so interlaced among the twigs that it would require next to a hurricane to displace them or roll them into bundles.—R. F.

TRADE CATALOGUES RECEIVED.

Catalogue of Choice Plants, Azaleas, Geraniums, Dahlias, Roses, &c.—Dillistone & Co., Sturmer, Essex; and William Dillistone, Munro Nursery, Sible Hedingham, Essex.

Alex. Gibb, Panmure Nursery, Broughty Ferry, N.B.—*Catalogue of Florists' Flowers, &c.*

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the "Journal of Horticulture, &c.,"* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

POLYANTHUS WITH LEAFY CALYX.—A reader of THE JOURNAL OF HORTICULTURE would be very glad to communicate with "C. Daniel" respecting the Polyanthus sport with a leafy calyx, mentioned at page 330.

PLANT CASE (A Three-and-a-half-years Subscriber).—We grow tender Ferns, Maranta tigrina, variegated-leaved Begonias, and dwarf Caladiums similarly variegated. We use the Bijou Plant Case, manufactured by Mr. Stocks, 14, Archer Street, Kensington Park, W.

FERNS FOR A GLASS CASE (J. M., Dumfries).—For a room scarcely ever having a fire in it we do not think that your selection for the case is suitable. Adiantum curvatum is a native of Brazil, and requires a cool stove or a warm greenhouse. Asplenium adiantum nigrum is very suitable, being a British species delighting in a shady place and growing in vegetable mould, brick rubbish, and pebbles. It is almost an evergreen, if not quite so. Lastrea bulbifera, or Aspidium bulbiferum, is a North American species, and suitable for the case. Adiantum capillus-Veneris is also suitable, being the Bush Maidenhair. Adiantum gracile, do not know; but fear it will be too tender. Adiantum formosum we think might answer, though it would be better of more heat. In such a cool case the fronds would get brown and withered in winter, but come fresh in spring and summer. Acrophorus hispidus, do not know it, and therefore cannot say if suitable; and fear we must say the same of Davallia longifolia, as all the Davallias we know are natives of warm climates. Instead of these tender ones, we would recommend such British Ferns as Allosorus crispus, or Parsley Fern, which should be planted shallow, and be kept well drained and moist. The fronds will always come green in spring; and such Aspleniums as fontanum, lanceolatum, viride, and marinum, all require peat, heath soil, broken bricks, and a little lime rubbish; and the latter the least of salt in the water. Cystopteris alpina and Trichomanes radicans, or Killarney Fern, require also to be shallow-planted in peat and moss, and kept in a cool, damp, close atmosphere. We think that with these you will succeed better and be better satisfied than with tropical exotics. Instead of planting in leaf mould and water sand, drain well, use a little old sweet leaf mould, but chiefly heath soil, and mix all with broken pieces of pots and bricks; and for sorts that cling to walls use pieces of stone. We would not leave the bell-glass off long at a time, but would merely elevate it a little; in fact, we would prefer a moveable top, so as to give a little air at pleasure. We would also daub the glass next the window and the top of the case to keep too bright sun out. The glass inside being dewed with water is all right enough. If you had a moveable top, and turned it the reverse way in the morning, the tenderest Ferns would not be injured by dripping.

VERBENA TO CONTRAST WITH PURPLE KING (M. M. P.).—We should select Evening Star; but Miss Mildmay or Loveliness would suit you among the older kinds. We do not know the best mauve-coloured that would thus contrast. Lord Leigh is a noble crimson scarlet with yellow eye, sent out by Messrs. Perkins, of Coventry, figured in the *Florist and Pomologist* of March, along with a beautiful purple, Lord Craven, now sent out by Downie & Laird.

FUCHSIA SHOOTS INJURED (Three-years Subscriber).—There are signs of thrips having been on the fuchsias. It would be safest to take them away from the rest and smoke them. There are also signs of the soil having got sour with stagnant moisture about the roots. If none of these are the causes, we are at a loss as to the reason.

MELON LEAVES DISEASED (Cucumis melo).—We think it is likely that there is too much bottom heat for these hardier kinds of Melons, which might be neutralised by a good layer of rubble between the pines and the sun. We can see nothing wrong in the treatment, more especially as other varieties answer so well; but, if not tried, we should adopt leaving a little air on all night, or, at least, giving air the first thing in the morning, however small the quantity, so that all moisture shall be dissipated from the leaves before the sun strikes them. Some of the Persian kinds will thrive in an amount of atmospheric moisture that would ruin some of the older and hardier kinds. We shall be glad to hear how you get on with them.

GOLDEN CHAIN AND OTHER GERANIUMS (Q. Q.).—You had better send leaves of the plants in dispute. Very likely one of your plants is golden-edged. We have just pulled off a leaf of Golden Chain at random. It is about 3 inches in diameter, but will be much larger in summer, yellow all round, some places a quarter of an inch, in others more than 1 inch deep, running into and mottling the green. The flowers are small nosegay blossoms of a bright cerise colour. For practical purposes we consider this and Cloth of Gold the best, and Golden Chain is so well known that some in your neighbourhood must be acquainted with it. If leaves are sent and numbered we would have no difficulty, we think, in deciding upon it; but we could not do the same with the many other Golden Chain mentions, many of which we have not seen. Cloth of Gold has fine scarlet flowers, as good or better than Tom Thumb; and the leaves, greenish-yellow in winter, become brighter yellow in summer. Sunset took our attention much, but we have not got it, and somehow we have seen it nowhere out of doors. We are just in the same fix as to white variegated Geraniums. Mrs. Lennox, Countess of Warwick, and many others are good. We prefer Bijou and Alma and the old Flower of the Day to any we have met with; but that is no reason why others should not have their Queens, Silver Queens, and even like them better than we do Bijou.

LIGHT BLUE LOBELIA (Idem).—The best blue Lobelia with a white eye we should presume to be Paxtoniana or Gordoniana. A strong-growing light blue to hang about would be the common gracilis, or, stronger still, begoniaefolia. Erinus is light and compact in growth. You may top your Zelindas for the purpose wanted; but for our part we have had them in dense bloom from July to November without stopping, by pruning-off the flowers as they begin to fade. To have bloom in mass in September and October you may stop and top now to your heart's content.

FLOWER-GARDEN PLAN—WARDIAN CASE (Mrs. C.).—We are sorry to say that neither the Lilac Candytuft nor the Nemophila will be likely to stand the season. We think it is quite likely the Saponaria will yet come up. If not, the best substitute would be a pink Verbena, as Favourite, Loveliness, &c., for No. 2; and if you wish No. 1 to be white, white Verbena Snowflake or variegated Alyssum for planting, or white Candytuft or white Alyssum for sowing. Much the same remark applies to No. 4, Purple Candytuft, which, if it blooms early, will not continue. You would notice in the plans of flower gardens the importance of having a centre. Yours can hardly be said to have one, but you write so clearly that we are tempted to say what we think would improve your arrangement. Let 5 and 6 be Calceolarias, yellow and edged with a small purple Verbena, as Charwoodii or Purple King. Then 1 and 4 we would make purple; and 2, 3 pink edged with blue; 7, 8, scarlet and white as now, and the rest ditto. You will succeed with Portulacas and the other things you name, simply by keeping the bottom of the case drier and giving more air—a little, at least, every night—and turn the glass cover in the morning to prevent drip. It will be best, therefore, to strike those that like a moist atmosphere at one time, and those that do not like so much at another time, or put a division in your case.

INSECTS (J. Gaitley).—The specimens enclosed by you are of the Snake Millipede, *Julus terrestris*. They have been charged with eating the roots of Pansies, and you state that they have "destroyed several rows of Peas." Try watering on each side of the rows with diluted ammoniacal liquor from the gasworks. This repeated once or twice a week may drive them away, and invigorate the Peas at the same time. We cannot say how much water you should put to a gallon of the liquor, for this varies in strength, but, probably, one of liquor to three gallons of water would do.

PEACHES AND NECTARINES FALLING (E. M., Ipswich).—As both the trees in pots and those in the borders shed their fruit, we think they are all too dry at the roots. We recommend you to water them with weak liquid manure of a temperature of about 80°. Give a good soaking that will penetrate down to the lowest roots.

RUSTIC VASES.—I purchased some of these pretty vases, but find that they look very white as if mildew had affected them. What is the composition wherewith they are coloured, and how is it to be applied? Perhaps some tradesman who sells them will be good enough to answer this.—D.

SEAWEED FOR ASPARAGUS-BEDS.—In answer to "W. M.'s" inquiry in your Journal of May 5, *F. W. B.* begs to state that he covered his Sea-kale bed in November, and began cutting the Kale early in February. *F. W. B.* has no doubt that an earlier crop might be obtained by applying the seaweed in September or October; but it is important that the fresh seaweed should be covered with earth to prevent its being dried up and losing all nutritive matter.—W. S. M.

ANTS IN PANTRY (Wiltshire Rector).—Powdered carbonate of ammonia sprinkled about their haunts, and persevered in for a few days, will probably drive them away.

VERBENA VENOSA (S. E. B.).—Any florist can obtain it for you. We know that it was in Messrs. E. G. Henderson's catalogue.

VARIOUS (S. J. W.).—The leaves of your greenhouse Rose are attacked by a parasitic fungus. Dusting with sulphur, more air, and more light would probably overcome the fungus. For the culture of Roses in pots consult "Florists' Flowers for the Many." You can have it free by post from our office if you send six postage stamps, with your direction. *Campanula pyramidalis* is a perennial. We have never heard before that cocoa-nut fibre refuse destroys plants by inducing fungi, and we believe such a statement is not founded on facts.

PROPAGATING THE HOLLYHOCK (A Subscriber).—This is easily done at the present time, by taking a few shoots about a yard long or so, and cutting them into lengths of two joints each, removing the leaves from the lower joint and inserting the cuttings in sandy soil under a hand-glass. Almost every cutting will grow. Any time in the early part of June will do. Later on in the year this propagating requires the assistance of a hot-bed, and is then more uncertain.

PEAR TREE NOT BEARING (Idem).—Pear trees cannot always be made to bear all over the tree as a Vine can be made to do. If your tree bears as many near the extremities as you think the whole tree ought to produce, you must not complain. A partial remedy, however, may be had by introducing some young shoots from the centre of the tree and training them between the older branches and removing the latter when the younger ones are far enough advanced; but the tendency to bear most on wood that is two or three years old, will always show itself in spite of all that can be done. Allowing the spurs to extend a long way from the wall will sometimes induce fruit in the centre; but the ugly appearance of the tree hardly justifies the plan.

PLANT DESCRIBED (A Subscriber, Kilmarnock).—Your "prickly Pear" we think must have been the *Datura Stramonium*, or Thorn Apple. It is a native of this country.

FLOWER-GARDEN PLANTING (An Irishwoman).—We think your proposed arrangements will look very well, and we presume your Shrubland Pet is all right. We have had, however, some trouble in finding the connections in your letter, and were you not a lady we would advise the beginning your tale at the first page of a sheet and going regularly onwards. We have had to twist and turn to find out what you meant or what you wanted, and we are sure you did it quite unthinkingly; but all correspondents asking such questions should endeavour to give as little trouble as possible.

TREATMENT OF QUICKSET HEDGES THE FIRST YEAR AFTER PLANTING (E. R. S.).—Unless the hedge be planted early in the autumn, it is best not to cut the plants down until the following season, when a much better result will follow. In the district where the best hedges are reared this is the practice, and it cannot well be improved.

PLANTS FOR STUMPS OF TREES ON A SUNNY SITUATION (Idem).—There is nothing better than some of the Tropaeolums, as Elegans, Edipse, &c. Ivy-leaved Geraniums are also good, and the Gold and Silver-edged Ivy itself looks very well and does well. Some of the hanging species of *Mesembryanthemum* also look well, as likewise does the variegated *Periwinkle*, and even *Scarlet* and other Geraniums do pretty well. On the other hand, *Calceolarias*, *Lobelias*, *Verbenas*, and such plants as like a richer soil and more of it, do not so well, as we expect the quantity of mould is too limited.

GERANIUM LEAVES SPOTTED (A New Amateur Subscriber).—The spot you complain of is mildew, caused, we think, by the plants receiving too much water, or, perhaps, being too much in the shade and not warm enough. After potting-off, bedding Geraniums of the *Scarlet* class require very little water until they begin to grow. We have never known the evil so late as you seem to have it, but it is common enough in the dark days, but disappears when more sun and drier weather set in.

PLUMBAGO CAPENSIS NOT FLOWERING (Idem).—If your plant was too much in the shade during the early part of the summer, it would not have time to prepare its flower-buds before the season was too far advanced for its blooming. Potting the plant after May is also more likely to produce wood than flowers. It also requires a house a little warmer than an ordinary greenhouse to induce it to flower well, although after it has flowered any cool house will do for it. It does better against a wall than against a trellis in a pot; but in the latter we have seen it do very well, and we have no doubt but you will succeed if the season be a warm one, and you are able to give it a little heat to begin the summer with.

FIGS IN A HOUSE DROPPING OFF (A. W. B.).—Most likely your Fig tree lacks water. At this particular time the Figs seem to revel in moisture, and the tree being in a house the usual moisture it would have received out of doors is denied it. Try watering well and stopping some of the shoots and most likely you will get the second crop to ripen, and more especially if you thin them freely if they show too abundantly.

ORANGE TREE NOT THRIVING (Idem).—If your tree was in bad health last year, it would have been better to have repotted it entirely, and ascertained if the drainage, &c., was perfect, as we suspect it is suffering that way, for although the Orange likes abundance of moisture, it does not like it stagnant. The warmth of a conservatory that is at present increased to encourage the growth of the Camellias, will not be too much for the Orange tree. On the contrary, it ought to suit it exactly. Better examine the roots, and if they be decayed and bad cut them in and repot in a rather more open soil with plenty of drainage and in a smaller pot, cutting back the top at the same time, and shade and syringe until the summer's growth is finished, when it may be gradually hardened and turned out of doors for a plenty, taking care that it does not suffer from too much rain and yet has plenty.

CATALPA NOT FLOWERING (H. P. B.).—Although we are told this tree flourishes in the swampy districts where the war is now raging in South Carolina, we are far from certain that a damp situation suits it in England. On the contrary, the places where it seems to flourish most are on dry stony or gravelly soils, where it flowers abundantly, and in the hot seasons of 1858 and 1859 it formed seed-pods. As your tree is so old, it would be better to procure a young one from a nursery to plant in some dry place, and in due time you will be favoured with flowers. It seems to require all the warmth of our hottest summers, and consequently in unfavourable situations or adverse seasons it does not succeed so well. We had but few flowers in 1860 and 1861, but before these times, and also last year, we have never failed in having abundance of flowers on trees planted on dry stony soils.

MOVING AN ARAUCARIA (Idem).—We are far from certain which is the best time to transplant this tree, as we once removed two in April, much alike in every respect, and one of them did remarkably well and the other one died. We are inclined to think that September is the best month; but we confess being uncertain on this point. Much depends on the condition of the tree to be moved, and other circumstances, as one that has stood a number of years in one place—and that place a particularly good one—cannot well be removed without suffering more or less; and as it is a naked-rooted plant, a ball with it is not easily obtained. Securing every fibre carefully and planting the same again, and spreading out as carefully as a tree is nailed against a wall, will generally insure success; but the season and other circumstances have much influence on this.

SEEDLING PANSIES (L. F. F.).—We do not discern anything new among them. There are two tolerable flowers—the one with pale lemon ground, good eye, back petals, and belt of deep purple; the other orange ground, small eye, back petals, and belt maroon; but these are inferior to many named varieties. It is very difficult to decide upon the merits of a Pansy from a single flower. Unless three good specimens are sent of each variety we cannot hazard an opinion. The other specimens sent were deficient both in form and substance.

SEEDLING CYCLAMENS (Cyclamen Ignoramus).—You cannot do better than let your seed-bed, pan, or pot alone until the plants develop themselves. Continue to give them sufficient water to prevent their suffering from want of it, and no more. By-and-by you will be favoured with foliage, which continue to encourage until the end of the growing season; after which let the plants go to rest in some cool place, secure from frost and heavy rain, yet not entirely dry, and most likely you will have a number of roots like small potatoes, the largest of which will flower next year.

TEMPERATURE FOR EPACRISSES AND AZALEAS CUT BACK (*A Subscriber*).—The Azaleas may have 50° at first, increasing to 60°. The Epacrisse much the same; but increase the heat gradually, and give a rest first of ten days or a fortnight. See "Doings of Last Week." You cannot have a better guide than Keane's "In-door Gardening," which you can have from our office free by post for twenty postage stamps.

SWEET-SCENTED GERANIUM AND VERBENA CUTTINGS (*Ignoramus*).—Nothing is more easy to strike than these, especially in spring, when cuttings may be put into ordinary sandy soil, with a little clean sand at top; and the pots being half plunged into some bed, with a little bottom heat, and slightly shaded for a few days, they speedily become plants; and by being allowed to remain there, the tops of Verbenas are often taken off and made into more cuttings. This is especially the case with scarce ones.

WATER FOR A CONSERVATORY (*A Subscriber*).—Why not have a tank sunk in the floor, with a gutter round the eaves of the roof communicating with the tank by a stock-pipe? We have found the rain collected from such a roof sufficient for the supply of all the inhabitants of a conservatory. If you live in the east of England, where the rainfall is least, the supply might not be quite enough. From such a tank, by the aid of a hydropump, you might water the plants easily and efficiently. If you fear that in excessive rains the tank might overflow, could you not have an escape-pipe from it? The tank might be outside, and even at a distance, by continuing the stock-pipe to it; and then any little iron pump might be fitted to the tank. When the tank is inside the conservatory, the water is always of a genial temperature.

RETARDING THE FLOWERING OF FUCHSIAS, GERANIUMS, &c. (*W. Miller*).—The greenhouse varieties of Pelargonium may be kept from flowering by being placed on the north side of a wall after being repotted, and pinching off the flower-buds as they appear, until the time when they are wanted. A like treatment will also enable you to have Scarlet Geraniums in good condition; or, if you let the latter flower as early as you can, and then cut off all the flowers and repot, the second crop will come in about the time you speak of. Fuchsias, when good, remain long enough in flower to satisfy most people; but you may retard them by turning them out of doors; and, if they were plunged in a gentle hotbed, with their tops quite exposed, short-jointed fine-grown plants would be just coming into flower at the time you want them. We do not know of any work bearing on the treatment of these particular plants, but much may be learned by reading our back Numbers on this subject.

GERMAN ASTERS ATTACKED BY BLIGHT (*H. C. Horton*).—This is a very common occurrence, but coming at a particularly busy time it is often neglected. A syringing with tobacco liquor will be of much use; and if any tokens of insects appear on the plants at the time of transplanting, it is easy to dip their tops in a weak decoction of tobacco. Generally speaking it is an aphid that is the cause of this evil. If, however, it be a mildew, sulphur may be applied; but this cannot be done so well except at the planting time, when their tops being dipped in tobacco liquor as above, they may then be dusted with sulphur, and will do much towards preventing the evil complained of.

WIND INJURING NEWLY-PLANTED CALCOLARIAS, &c. (*W. C. H. D. A.*).—It is not unlikely but the late winds may have been hurtful, if not fatal, to a great many things; but in your case we would advise the Calcocalarias being left alone, when they will recover in time. We suspect your plants have been too much coddled before planting-out. Ours of the same kind were planted-out early in April, having previously been fully exposed for some weeks before; and now they are dwarf, bushy, fine plants, only waiting for a good rain to start them into vigorous growth and flowering. Cutting down the plants in their present condition will only retard their ultimate success. If you had taken the precaution of sticking or laying a few laurel boughs over your bed, much injury from the wind would have been averted.

PROPAGATING DOUBLE CHINESE PRIMULA (*H. T. G.*).—You must wait until you can obtain side shoots about $\frac{1}{2}$ inch long, when they may be taken off with the knife and inserted in sandy peat, and placed in the striking-pit or hotbed. Generally, it is best to allow a plant to grow to a good size and then to cut it into pieces, and each cutting or side shoot will become a plant. This is better than mutilating specimens, as they furnish cuttings only tardily.

NAMES OF PLANTS (*S. Lake*).—1, *Rhododendron glaucum*; 2, *Boronia tetrandra*; 3, an *Oxalis*, apparently *violacea*. (*M. B., Staffordshire*).—Nothing but *Cystopteris fragilis*, though a small neat form. In *Gladiolus* the accent is on the *i*; in fact the *o* is not pronounced at all. (*H. P. D.*).—1, *Koniga maritima variegata*, or *Alyssum maritimum variegatum*; 2, *Arabis alpina variegata*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY SHOWS.

MAY 28th. NORTH HANTS. Sec., Mr. Henry Downs, Basingstoke. Entries close April 23rd.
JUNE 3rd. BEVERLEY. Secs., H. Adams and J. Kemp, jun.
JUNE 11th. THORNE. Sec., Mr. Jos. Richardson.
JULY 2nd. PRESCOT. Sec., Mr. James Beesley.
JULY 20th to 24th. WORCESTERSHIRE. Sec., Mr. J. Holland, Chesnut Walk, Worcester. Entries close June 20th.
AUGUST 29th. HALIFAX AND CALDER VALE. Sec., Mr. W. Irvine, Halifax.
SEPTEMBER 2nd. COTTINGHAM. Sec., Mr. J. Brittain.

QUERIES ABOUT BIRDS FOR EXHIBITION.

A VERY valued correspondent wishes for a sort of chatty paper on points that have an interest for him just now. We believe many are in the same predicament; and as it is rather soothing to our ideas of our own knowledge of the subject and of our own position in the poultry world to be appealed to, we think we will have a familiar "talk" with our friends. We will dismount and speak with them on level ground.

We know the difficulty of getting perfect birds as well as any

one—we consider it almost an impossibility. Our correspondent puts it so well and truthfully, that we cannot do better than quote from him. "You know the difficulty of getting a perfect bird; and when by eye you have selected an Apollo, you find on handling his breast is a few degrees out of the straight line. Would such a fault be destruction to his hopes as a prize bird?" If the competition were very close we say it would, but it must be very close. There is only one breed in which a crooked breast is a positive disqualification, that is in Game.

We think we can easily show why that is venial in one which is fatal to the other. The ends of the two breeds are opposed. In one we want hard flesh and feather, perfect symmetry and harmony of shape, the greatest possible endurance and activity. The two last properties must depend, not only on faultless proportions, but on strength of constitution.

It is undoubtedly true that in some cases a crooked breast is an hereditary failing, but in others it is the result of fast growth and of early hatching. The Game fowl is not hatched in January; his properties can be developed only by taking advantage of every favourable circumstance—warm weather, short nights, and natural season: hence he generally enters the world in April or May. He is not bred for the table, and is treated with stimulants at all ages. The Dorking is the reverse. He is bred only for the table. Hardness is a defect with him when a chicken; nourishment is substituted for stimulants. He is required to be quiet and easy to acquire size and to put on fat. The profit of the breed depends much on early hatching. The chickens see the light in January; by dint of food and painstaking they are large chickens in March—too large for maternal care, and they perch. This is the root of the evil. The sharp, clever, strong Game chicken clasps the perch with his toes, holds on securely and without effort in July when he is three months old. The heavy forced Dorking is a large fowl at the same age, and he attains it in March. He has to perch five hours longer than the Game; his large long frame and rapid growth, unfavourable to muscular development, have not strength in the feet to clasp a perch and maintain the position by the mere fact of doing so. He attempts it, but the feet get gradually wider apart, and the body descends little by little till at last the long cartilaginous breastbone rests on the perch, and it remains there during the long hours of a winter's night. As this is constantly occurring, there is small wonder if it takes the form of the perch, or, at least, contracts a curve. It seems to us that this explains why the same thing may disqualify one bird and be allowed in another. We still hold a crooked breast to be a defect, but we do not think it should disqualify a Dorking.

Now we have to deal with another query. "Which is the greater fault—a somewhat irregular foot or curvature of the breast?"

We do not know what an irregular foot is. Has it only four toes? Is it clubbed? Is it turned the wrong way? Whichever it may be, we prefer the breast-curvature for competition. This latter will be detected by handling only. The other is plain to the sight, and will at once disqualify, rendering useless all the good qualities that handling might discover.

"Are very early birds to be relied on for Birmingham? My January pullets are laying."

April and in some cases May birds are early enough for winter exhibition; as a rule among pullets we would at a December show rather take May than January birds for success. The latter are hens.

"Do you think it well to keep the sexes separate?"

In selecting birds either for stock or exhibition we would always keep them separate if we could. It is more important for the cocks than pullets. If they can be kept separate till they are eight or nine months old it is much in their favour.

AGRICULTURAL HALL POULTRY SHOW.

IN connection with the Great International Dog Show that is held during the present week at the new Agricultural Hall at Islington, a Poultry Show has been organised.

This is held in the minor hall, a very large well-lighted structure that is admirably adapted for the purpose. The pens, which are of wire, are arranged round the sides, and also form three double rows down the centre, with wide aisles between capable of accommodating a very large number of visitors.

The general management is in the hands of Messrs. Douglas

and Blythe, both well known as possessing great experience in conducting poultry shows to a successful termination.

At this early period it is impossible to give a detailed and very critical account of the proceedings, which must of necessity be deferred until next week's Journal. We may say that most of the well-known exhibitors have entered, and that the Game classes are unusually full and good for a London show. Dorkings, of course, are well represented, and all the varieties of Hamburgs muster in very good force.

Subjoining the prize list we defer our further remarks until our next issue.

SPANISH.—First, Viscountess Holmesdale. Second, R. Wright. Third, J. Root.

DORKING.—First and Second, Viscountess Holmesdale. Third, J. Drewry.

COCHIN-CHINA (Buff or Cinnamon).—First, C. T. Bishop. Second, T. Stretch. Third, S. Statham.

COCHIN-CHINA (Any other colour).—Captain Heston. Second, R. Chase. Third, E. Tudman.

HAMBURGH (Golden-pencilled).—First, J. E. Powers. Second, N. Barter. Third, A. Nuttall.

HAMBURGH (Silver-pencilled).—First, Viscountess Holmesdale. Second, H. Beldon. Third, J. Dixon.

HAMBURGH (Golden-spangled).—First, S. H. Hyde. Second, N. Marlor. Third, H. Carter.

HAMBURGH (Silver-spangled).—First, T. Davies. Second, H. Beldon. Third, H. Carter.

GAME (Black Reds).—First, Capt. Wetherall. Second, J. Fletcher. Third, S. Matthew.

GAME (Brown Reds).—First, Rev. F. Watson. Second, M. G. Ashwell. Third, S. Matthews.

GAME (Duckwing).—First, R. Gilbert. Second, J. Fletcher. Third, G. W. Langdale.

GAME (Any other variety).—First, W. Dawson. Second, H. Adams. Third, Rev. G. S. Cruwys.

ANY VARIETY (not named).—First, T. P. Edwards (White-crested Black Polands). Second, P. P. Cother (Pheasant Malay). Third, J. Dixon (Polands).

BRAMA POOTRAS.—First and Third, C. Priest. Second, J. Hinton.

GAME BANTAMS (Any variety).—First, R. B. Postans. Second, W. J. Forrest. Third, G. Manning.

BANTAMS (Gold and Silver-laced).—First, Rev. G. S. Cruwys. Second, T. H. D. Bayley. Third, G. Manning.

BANTAMS (Other varieties).—First, Capt. F. Marten (Japanese Mufflers). Second, Capt. Wetherall (White). Third, Miss K. Charlton (Black).

SWEEPSTAKES.

GAME COCKS.—First, J. Stubbs. Second, H. Adams. Third, A. B. Dyas.

BANTAMS (Game).—First, T. H. D. Bayley. Second, N. Sykes, jun. Third, J. Camm.

JUDGES.—Mr. Hewitt, Sparkbrook, Birmingham; and Mr. Tegetmeier, Muswell Hill, London.

GAPES IN FOWLS.

UPON the parasitical worm causing this affection in poultry and some other birds, Professor Simonds recently made the following observations:—

"With regard to fowls and the existence of worms in their windpipes; in that case the worm is not the *Filaria bronchialis*, nor is it allied to that description of worm.

"It is termed *Syngamus trachialis*, and believed to be the connecting link between the bi-sexual worm and those in which the sexes were separate and distinct. The worms very rarely exist in larger numbers than about two or three, though he had met with as many as five in the windpipe of a chicken. It is a true blood-sucker—in fact, a leech. It fixes its head in the mucous membrane, and exhausts the power of the chicken by sucking its blood.

"Another curious feature in reference to this worm is, that it is met with in all the gallinaceous tribes of birds, whether wild or domesticated: hence it is the cause of great loss in the rearing of Pheasants and Partridges. Great numbers of Rooks also are killed by it; but, singularly enough, aquatic birds, such as Ducks and Geese, might march about with perfect impunity amongst thousands of other things affected with the *Syngamus*.

"The mode of getting rid of the worms is entirely mechanical—passing a feather into the trachea, and giving it a sweep round. The worm attaches itself to the barbs of the feather, and so is brought away. That being the case, there is no occasion for the feather to be dipped in turpentine; on the contrary, dipping the feather into turpentine is more likely to kill the chicken. A great many chickens, however, are destroyed by this means; and he believed that they could best get rid of the worms by making the birds inhale a medicated air, and inducing them to take up little pellets of food mixed with assafetida and turpentine. Let a few grains of barley, for example, be steeped in turpentine, and be thrown down with others to the poultry. The birds would then pick up the grains indiscriminately, and if they picked up

the steeped grain with the other the worm would thus be got rid of. The fumes of tobacco are also an excellent remedy. Let the chicken be placed under a tub propped up a little on one side; then burn the tobacco on the outside, and let the draught carry the smoke into the tub. Do this, and with the assistance of assafetida pills, they would even destroy the *Syngamus trachialis*."

FOOD OF CHICKS PREVIOUS TO WEANING.

STOPPY matters are better avoided till the little things are old enough to eat a few grains of good wheat, of the best sample, which will not be thrown away upon them. Meat and insect diet are almost necessary; but raw vegetables chopped small, or Indian meal dough, containing no salt, so grateful to young Turkeys, are *caviare* to chickens. But whatever the bill of fare, the meals must be given at short intervals; as much as they can swallow, as often as they can eat. The reader will please to remember that when he came into the world, all that was expected of him was to grow and be good-natured. He had not to provide his long clothes out of his mother's milk, nor to elaborate pinafores from a basin of soaked biscuit: but for poor little chickens, the only known baby-linen warehouse is situated in their stomachs. And with all their industry, they are only half clad, till flesh and blood stop growing for a while, and allow down and feathers to overtake them.

The period at which they are left to shift for themselves depends upon the disposition of the hen. Some will continue their attentions to their chicks till they are nearly full grown, others will cast them off much earlier. In the latter case, it may be as well to keep an eye upon them for a few days, till they have established themselves as independent members of the gallinaceous community; for chickens, in this half-grown state, are at the most critical period of their life. They are now much more liable to disease than when they were apparently tender little weaklings crowded under their mother's wings. It is just before arriving at this point of growth that artificially-hatched chickens are so sure to fail, whether hot air, hot water, or sheep skins be the substitute for the mother's care.—(*Prairie Farmer*.)

FOOD ESCAPING FROM BOTTLE-FEEDERS.

LIKE your Devon contributor at page 303, I too was prone to ascribe the very considerable slope my boards had when the bees were solely under the protection of the straw hackle, having something to do with the evil (but not a wide-mouthed bottle, as I have never fed with one over an inch), the more so as I was once greatly surprised in the spring at the effect an extreme slope had on the ventilation of a colony, causing an amount of evaporation at the entrance, far in advance of the colony's real strength.

Some alterations in my apiary at the end of last season induced me to bring the boards exactly level, without at all affecting these disagreeable escapes of food. One of my best queens, by the way, the last time I had the pleasure of an interview, I observed had her full share of this unwelcome shower-bath.

The cue to solve the enigma is, that such escapes rarely occur but in the mornings, and then almost invariably after frost. Upon discussing with your last-named correspondent this same leakage question in No. 36, I recorded having found quite an accumulation of food on the board of a weak colony, which perished during a long frost, an unemptied bottle being upon the board.

Whether or not the frost causes the bees to desist from removing the food is the explanation, or if it in any way effects some change on the suspended food itself, liquifying it to a certain extent, and inducing the running at a milder temperature may possibly be explained by some of your correspondents more philosophical than—A RENFREWSHIRE BEE-KEEPER.

BRITISH BEE-BOOKS.

IN the series of articles, of which this is the first, I propose giving a short account of all the distinct treatises on bees which have been published in the United Kingdom. Several incomplete catalogues of apian works exist. There is an alphabetical list of bee-books in the Rev. W. C. Cotton's "Bee-Book." This, however, is imperfect, and appears to have been a list of the works in the author's library.

In Milton's "Practical Bee-keeper" there is a list of writers names chronologically arranged. This last, like Mr. Cotton's

includes foreign as well as English writers, and comprises the names, not only of the authors of distinct treatises, but also of those who have made the slightest allusion to bees or bee-keeping.

The plan I propose to adopt differs essentially from either of these. I intend to give the titles of the works in full, with the date of every edition, the size, number of pages, &c., and to append a short account of the character of the work.

I hope to include every separate treatise, however small, and also the more important articles from the proceedings of learned societies. Articles in magazines and newspapers will not be noticed, as it would be impossible to compile a complete list of these fugitive papers. The list will be arranged chronologically, the time being taken from the publication of the first edition.

I conceive that I possess peculiar qualifications for the task I have undertaken. I have a great interest in the subject, and am in possession, I believe, of the most extensive collection of apian works.

I cannot hope, however, to make my list complete without the assistance of the numerous collectors of bee-books. Many works may have escaped my notice; and should I omit any, I hope some of the readers of *THE JOURNAL OF HORTICULTURE* will help to render it complete. As it is proposed to publish the list subsequently in a separate form, any suggestions that may increase its value will be very gratefully received.

The first distinct English treatise on bees of which I can gain any intelligence is that of Hyll or Hill, published 1568.* The Rev. W. C. Cotton, however, gives a title as follows:—

"Bee, a numerous genus of insects, which have attracted an uncommon share of attention in all countries, and in every age, on account of their Industry, Art, and Utility. 1539." It appears obvious that there must be some mistake—the language of the title is not that of the period; nor can I find any such book in the British Museum or other library. Can any readers of the *Journal* give information on this work? In the meantime, regarding Hill's as the first English treatise on the subject, I give the titles in full.

1568. HILL. "A pleasaunt Instruction of the parfitt orderinge of Bees with the marueilous nature propertie and gouernement of them and the myraculous uses, bothe of their honny and waxe (seruing diuersly) as well inward as outward causes; gathered out of the best writers. To which is annexed a profitable treatise intituled certain husbandly coniectures of dearth and plentie for euer, and other matters also meet for husbandmen to knowe and which is now Englished by Thomas Hill, Londyner. 1568."

This edition has a portrait of the author at the back of the title, and at the end "Imprinted at London in Fletestrete neare to S. Dunstones Church by Thomas Marthe. 1568." This edition is in 12mo. black letter; and, like the other editions, is appended to his "Arte of Gardening," but is pagged separately and has a distinct title. The first edition of Hill's Gardening is in 12mo. London, 1563. It is entitled "A most briefe and pleasant treatyse teachynge how to drees sow and set a garden." This edition does not contain the treatise on bees.

The subsequent editions of Hill's treatise vary so much in the title and size that it is desirable to print that of 1574.

1574. HYLL. "A profitable instruction of the perfite ordering of Bees, with the maruellous nature, propertie, and gouernemente of them and the necessarie vses both of their Honie and waxe seruing diuersly, as well inward as outward causes: gathered out of the best writers. To which is annexed a proper Treatise intituled: Certain husbandly coniectures of dearth and plentie for euer, and other matters also meete for Husbandmen to knowe, etc. By Thomas Hyll. Londoner. Imprinted at London, by Henrie Bynneman. Anno 1574." Small quarto, fol. 88. Black letter.

This edition has on its last page "Imprinted at London by Henrie Bynneman, dwelling in Knightryder streate at the signe of the Mermayde, anno 1574," and printer's monogram of mermaid.

1579. This edition, quarto, fol. 92, was also printed by Bynneman.

1586. The edition of this date has the same title, with imprint as follows:—"Imprinted at London by Robert Waide-graue. 1586."

1593. Same title. "Imprinted at London by Edward Alde. 1593."

* The earliest printed work on the subject is, I believe, an extremely rare continental work in monkish Latin. Date about 1510, with a running title, "Boni universalis de proprietatibus apum." Of this curious book I hope to give some account at a future time.

1608. Same title, except "By Thomas Hill, Londoner. Imprinted at London by H. B. 1608."

All these editions of Hill are in the library of the British Museum. Hyll's treatise contains little practical instruction, and is confessedly a compilation from "the bookes and volumes of many and diuers antient writers." Butler, in the preface to his "Feminine Monarchie," speaks of Georgius Pictorius, a learned Physician, as having taken most paines in perusing the ancient authors, and adds: "Whom one T. H. of London translating word for word into English, as well as he could, concealing the authors name, adventured to publish in his owne name."

Hill's work is divided into forty chapters, the titles of which give a very good idea of the nature of the information they contain. Thus "Chap. 3. How bees do naturally engender." "They lay eggs," says our writer, "setting on them as hens do on their eggs, and when they have sit on them for the space of 45 daies they do hatch their yong ones which yong at the first do come forth much like to white wormes except the king who only as he is hatched hath wings." Chap. 8. "The marueilous gouernment of the king of Bees and of the obedience which the vse to him."

In the chapter on the best kinds of hives, he describes English hives as being of straw, and says that the hive ought to be 1½ or 2 feet high, and in breadth above 2½ feet or somewhat larger; and in chapter 3 he describes observatory-hives formed of thin and clear horne belonging to a certain Consul at Rome, in which Guilielmus de Conchis observed the different kinds of bees.

The method of obtaining the honey from the hives was by making a smoke by burning linen rags or straw in a pot, setting this within the hive, and subsequently turning the hive up and cutting out the surplus combs.

In Milton's chronological list the next work is "1572, Anonymus." I know of no work corresponding to this date, nor did I see any at the sale of Mr. Milton's books.

May I be allowed to ask that any of my readers who have other apian works before 1600 will kindly oblige me with the titles in full?—W. B. TEGETMEIER, *Muswell Hill, London, N.*

[THOMAS HILL, HYLL or HYLLE, was a mere booksellers' hack, writing upon any subject required, and being no authority upon any. Works of his are extant on arithmetic, astronomy, bees, dreams, divinity, gardening, and physiognomy. He was probably a native of the metropolis, for on all his title-pages he is entitled "Londoner." One work, "The Gardeners' Labyrinth," he published under the name of "Didymus Mountain," which are only mongrel synonymes of his real name "Thomas Hill." He was dead when an edition of that work was published in 1586.—EDS. J. OF H.]

OUR LETTER BOX.

ROUFFY FOWLS (*C. J. S.*).—As a rule no fowl can be depended upon that is bought out of a coop in London, as seven-eighths are either diseased or will be in a day or two. The condition in which they are seen explains this—in a confined cage or basket, not always the cleanest in the world, injudiciously fed, and deprived of almost everything that is necessary for health, instead of fresh air and cleanliness, they are packed closely with all sorts of disease, and the coups are never untended. Kill all the worst cases. Have every house thoroughly cleansed and lime-whited. Feed your fowls freely on bread steeped in strong ale, and as soon as you have any grass carried, let them have the run of the fields. Above all, let the hens and chickens be put there.

HEN PIGEON NOT LAYING (*J. Robinson*).—Your hen sitting on a nest but not laying, is most probably barren. The only treatment likely to be of service to her is to give her an egg or a pair of eggs to hatch and rear the young. Afterwards, possibly, she may lay. Barren hens are by no means uncommon.

CANARIES DYING (*W. H. H.*).—The only reason we can assign for your birds dying in your mixed aviary is that the stronger birds will not allow the weaker to feed. We would recommend you to place more feeding-boxes in the aviary. The oiled boards do not affect the birds.

ILL-FLAVOURED BUTTER (*M. W. H.*).—The plant you enclose is *Ranunculus acris*, about the most blistering of the genus, and usually avoided by cattle. If your cow has only a small pasture, and this weed abounds, it is possible she may eat it, and that it may cause the butter "all through the year to have a bitter and often a semi-rancid taste." You may eradicate the weed by having it pulled up by the roots as often as it appears, which can be easily done after rain. On no account let it seed. Those who pull it up should wear gloves, or their hands will be blistered and inflamed by its juice.

DARK LIGURIAN DRONES (*J. L.*).—The drone accompanying your letter is so dark as not to be distinguishable from the common species, and yet it may be true Ligurian for all that. Some of the purest queens breed very dark drones, and, what is very singular, these sometimes become the fathers of a more than ordinarily handsome Ligurian progeny.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 69.1° and 46.3° respectively. The greatest heat, 90°, occurred on the 7th, in 1840; and the lowest cold, 35°, on the 5th, in 1856. During the period 141 days were fine, and on 111 rain fell.

GARDENING IN DEFIANCE OF DIFFICULTIES.

Cape of Good Hope and the South Pole.

Gardening is not less enthusiastically clung to; and as it is among our pursuits most worthy of such adherence, so most assuredly are those who pursue it among the most deserving of our fellow-countrymen. A few illustrative facts, therefore, merit recording.

If there is any locality where gardening would be abandoned, we should have expected that it would be in a region of perpetual snow, where artificial heat could not be obtained to compensate for the deficiency of solar influence. Yet even in such a region gardening lingers; and, in the beginning of August, the Rev. S. W. King writes thus about the Monastery of St. Bernard:—

“Before it became dusk we sallied out and faced the Spitzbergen-like weather for a scramble among the rocks and to the site of the ancient Temple of Jupiter. For some little distance from the Convent a sheltered terrace, scarped on the face of the rock, or piled on stones, and catching what sun there is when it shines, forms the only level bit of promenade the monks have outside their own walls. The further part of this, however, was now buried under a steeply-sloping bed of deep snow left from last winter, and almost touching the ‘Convent Garden’—two terraced patches within low walls, 4 or 5 yards square, in which grew a few tiny Lettuce, almost microscopic, and two or three equally diminutive representatives of the Cabbage tribe, name unknown. De Saussure’s description in 1778—‘Ils ont peine à produire à la fin d’Août quelques laitues et quelques choux de la plus petite espèce, pour le plaisir de voir croître quelque chose’—might have been written that week. Perhaps this forlorn attempt at a garden, with the thought that it was the height of their few weeks of summer, dark clouds of sleet sweeping over us, and whitening the little Lettuces, while we had left all bright and glowing in the valley below, gave us a more forcible impression than anything else of the dreary life of self-sacrifice to which these worthy men devote the best years of their existence.”

We all know that to the studious mind a change of subject, though still requiring thought, is a relief; yet

there are academical studies of such dry abstract quality, and requiring such a peculiar mental formation, as would lead to the belief that they could have no sympathy with gardening, and mathematics would seem to be of that quality—yet Humphrey Newton, who acted for some years as Sir Isaac Newton’s amanuensis, speaking of Sir Isaac’s habits whilst at Trinity College, says:—“He was very curious in his garden, which was never out of order, in which he would at some seldome time take a short walk or two, not enduring to see a weed in it.” Nor did Sir Isaac restrain his gardening efforts to the small enclosure of his own garden; for he endeavoured to establish cider orchards at Cambridge, and the following, written in November, 1676, was addressed to Mr. Oldenburg, then Secretary of the Royal Society:—

“I am desirous to write to you about procuring a recommendation of us to Mr. Austin, the Oxonian planter. We hope your correspondent will be pleased to do us that favour as to recommend us to him, that we may be furnished with the best sort of cider fruit trees. We desire only about 20 or 30 grafts for the first essay, and if these prove for our purposes they will be desired in great numbers. We desire grafts rather than sprags, that we may the sooner see what they will prove.”

In more modern times we have read of a well-known University Professor who adhered to gardening, though his pallisaded plot required for culture no tool larger than a trowel, and whose enthusiasm gave rise to this witticism—

“Professor Jowett a little garden made,
Enclosed within a little pallisade.
A little garden taketh little wit to show it;
And little wit had little Doctor Jowett.”

Turning to the soldier, we might expect that whilst on active service his spear would never be resigned for the pruning-hook. Yet this is not so; and even the Duke of Wellington, when Colonel Wellesley, resolved to cultivate Potatoes in Mysore as they were cultivated in Ireland, his native country. He sent presents to English ladies in Mysore of Cabbages and Celery, plants he had reared around the blood-stained walls of Seringapatam, and seemed as proud of his gardening in peace as of his generalship in war.

Nor is such an adherence to horticulture only within the power of a commander-in-chief; for we read that whilst our army was beleaguering Sebastopol Lord Raglan repeatedly visited the tent of Colonel Shadforth, then commanding the 57th, and was so much pleased with the great taste displayed, the small garden laid out with the greatest nicety. Roses trained so as to form a covered approach to the poultry-yard, and the whole in such good keeping, that the Commander-in-chief was pleased to observe, “Henceforth, when addressing any communication to you, I shall address you, ‘Colonel Shadforth, Shadforth Castle.’” On one occasion, when he walked to Balaklava to make arrangements for the comforts of his men, he lost his way, and did not reach the camp until twelve o’clock at night, and he was considered to have been taken prisoner. Upon its being

known that he had safely arrived, a great many of the 57th turned out, and gave three hearty cheers of welcome, to the astonishment of many in the camp.

The taste descended to still lower grades, and the well-known correspondent of the *Times* has left this record from the camp:—"The taste for gardening is, I am glad to say, well developed; and it is all the more graceful and laudable that it is indulged in under the most disadvantageous circumstances. Most seeds have a decided cryptic character here, and refuse to come up and look at the sun. If they do, there are rats, the cats, the dogs, and the fowls at them night and day—besides flies and ants, and creepers of an infinite variety and shape, and a multiplicity of legs, claws, teeth, and nippers. The French have been more successful than ourselves; perhaps they had better ground, and paid more attention to watering. Their little gardens by the Tchernaya are quite green, ours are generally of a fine Vandyke brown. Military horticulture is of an eminently culinary character. None of your Fuchsias or Camellias, or pretty plants and flowers with ugly names, but strong-smelling, vigorous potherbs—they are the *desiderata*. An acre of Mignonette is not worth a square yard of 'Spring Onions'—miles of glowing Orchids would not be compared for a moment with a few Lettuces, or even a good bed of Dandelions, of which the French have taught us to make a pungent and excellent salad. The longing for 'green meat' is but imperfectly satisfied, notwithstanding the number of coasters which come into Balaklava, and notably into Kamiesch, laden with vegetables. When a man asks you to dinner, his lure is not fish or game, or even a turkey, or a bustard from Sinope, but 'a jolly salad.'"

Let us pass next to within the prison's walls and cells. Locks and bolts and chains cannot exclude gardening even from thence. Man loves to look upon plants—if only, like Ophelia's Rosemary, "for remembrance." Warren Hastings bore evidence to this feeling. His partiality for his seat at Dalesford, bought on his return from India, is well known. "There is a small wood near the house," he said to Lord Redesdale, "the flowers and paths of which I had on my mind all the time I was in the East. In the house I passed much of my infancy, and I feel for it an affection of which an alien could not be susceptible."

Then who does not know the story of "Picciola" and the plant which soled the prisoner? Turning to more modern times, and scarcely able to credit that so recently as 1811 Leigh Hunt and his brother were tried, condemned, and imprisoned in Horsemonger Lane Gaol for speaking of the Prince Regent as a middle-aged Adonis! we find Leigh Hunt thus describing how he triumphed over the tyranny:—

"I papered the walls with a trellis of Roses; I had the ceiling coloured with clouds and sky; the barred windows were screened with venetian blinds; and when my bookcases were set up with their busts and flowers, and a piano-forte made its appearance, perhaps there was not a handsomer room on that side the water. Charles Lamb declared there was no other such room except in a fairy tale. But I had another surprise, which was a garden. There was a little yard outside, railed off from another belonging to the neighbouring ward. This yard I shut in with green palings, adorned it with a trellis, bordered it with a thick bed of earth from a nursery, and even contrived to have a grass plot. The earth I filled with flowers and young trees. There was an Apple tree from which we managed to get a pudding the second year. As to my flowers, they were allowed to be perfect. A poet from Derbyshire (Moore) told me he had seen no such Heartsease. Here I wrote and read in fine weather, sometimes under an awning. In autumn my trellises were hung with Scarlet Runners, which added to the flowery investment. I used to shut my eyes in my arm-chair, and affect to think myself hundreds of miles off. But my triumph was in issuing forth of a morning. A wicket out of the garden led into the large one belonging to the prison. The latter was only for vegetables, but it contained a Cherry tree, which I twice saw in blossom."

Than that we could have no more forcible illustration of the truth told in the old cavalier verse—

"Stone walls do not a prison make,
Nor iron bars a cage;
Minds innocent and quiet take
These for a hermitage."

The courts and alleys of the democratic portions of London are in some respects worse than prisons, yet gardening is not banished even from them.

We have often wondered what extent of cultivation these minds, in the neglected parts of London, are capable of, that display so much refinement in the assiduity with which they nurse a wild Daisy, or Primrose, in a fractured teapot or ginger-beer bottle. There is surely something more than the mere animal development here. Our attention has been more immediately directed to this subject, in consequence of the immense quantities of the commoner flowers which are, at this season, continually forced upon our observation, both in the markets, in the streets, and on hawkers' trucks. The Primrose, Daisy, Wallflower, Polyanthus, and Southernwood, are among the most popular; and in almost every lane, alley, and court, may be seen the various degrees of success with which these are kept in life. It is not only in the dwellings of the poor, however, that we have remarked this fondness for gardening. It would seem that some, who, perhaps, have no dwelling at all, or such an one as does not afford the facilities for indulging even this harmless gratification, resort to other means; and it was but the other day we encountered, in our peripatations, a well-cultivated and fertile spot on the fore-deck of a coal-barge! Who of our readers would ever have dreamt of a flower-garden in such a spot? Even our assiduous friend, Mr. Beaton, with all his train of fair followers, could never have thought of looking for a flower garden in such a spot, and that, too, floating on the very bosom of old Father Thames. And a very pretty garden it was. There were no circuitous walks, no ingenious devices, no grouping of colours; but there were some bright Anemones, of all colours; Polyanthuses with trusses as Polyanthuses never trussed before; double lilac Primroses; Hen-and-chicken Daisies, eclipsing in interest the finest poultry-yard of the greatest fanciers; lumps of Stonecrop, trailing down the sides of old tin tankards; "Bloody-walls," or "Warriors," looking as gay as any officer of the household guards; "Daffydownillies," as our ancestors called them, all rich in beauty, and some replete with fragrance; with here and there bushes of grim Southernwood, and the whole artfully and tastefully enclosed with an edging of the whitest of oyster-shells. We have interesting scenes in London which the rest of the world know not of; and such a scene as that now described is more gratifying to us by far than the luxurious and ready-made window decorations of Belgravia.

There is one place yet where a novice might not expect to find a love of plants lingering—the chamber where sickness has long saddened, and in which death is looked to as a rescuer. Even there the love of vegetable beauty, cultivated plants and their associated memories, are still cherished.

"During our late visit to the distressed districts," says the editor of that excellent periodical, "The British Workman," "we met (in a cottage in Wigan) with a pleasing illustration of the value of a flower. Although the man and his wife were starving

for food, and many articles of furniture had been disposed of for bread, we were interested by seeing in the window a beautiful plant.

"On remarking, 'Ah, my friends, I am glad to see that you are fond of plants. Be assured that He who cares for the flowers of the field, and the birds of the air, will not be unmindful of you; He will surely send you help.'"

"'Oh, yes, sir,' was the reply, 'we should not like to part with that.' In further conversation, we found that the little plant was truly a comforter to the worthy couple in their distress and solitude.

"Very similar is this case to that of the poor dying female, who was once found laid on a straw pallet in a garret; not a single article of furniture in the room, but in the window stood a little plant. To the visitor she said, 'As I have watched that little plant grow, I have been comforted with the assurance that God, who made it, cares for me.'"

"Fathers and mothers, train up your boys and girls in the cultivation and love of plants. It will do good to them as well as yourselves. Flowers are comforters!"

THE ROYAL HORTICULTURAL SOCIETY'S EXHIBITION.—MAY 27.

THE vast area of the Great Exhibition, so long empty and silent, was on Wednesday last again full of life and bustle, for it was there that the first of the great Shows of the Royal Horticultural Society was held. The structure would have sheltered an unlimited number of visitors from the weather; but fortunately its capabilities in this respect were not put to the test, for the day was one of the loveliest of early summer, and free from those chilling north-easters which have lately prevailed to the alarm of the gardening community. The attendance of visitors was, consequently, very large, notwithstanding that there had been a flower show at the Regent's Park but a week before, and one at the Crystal Palace only the Saturday previous.

Just before the general public were admitted, their Royal Highnesses the Prince and Princess of Wales, attended by the Duke and Princess Mary of Cambridge, honoured the Show with a visit. They were received at the entrance by his Grace the President and other members of the Council of the Society, and were escorted through the Exhibition by Mr. W. Wilson Saunders, the Secretary; and their Royal Highnesses, by the manner in which they examined the splendid examples of horticultural skill which lay before them, evinced an interest in horticulture that must have been highly gratifying to every lover of the art.

The objects exhibited were ranged on each side of the nave, which from its great breadth permitted a freedom of motion which is rarely enjoyed at floral exhibitions where crowding is usually the order of the day. Indeed, this was the only occasion in our experience when it was possible with a large concourse of visitors to examine the plants with comfort. We heard it objected by some that the height of the roof had the effect of making the plants seem less than they really were, and this certainly was to some extent the case, and it was urged that a screen similar to that employed at the Crystal Palace should have been used; but then it must be remembered that the roof there being of glass admits a much greater amount of light than that of the nave of the Great Exhibition building. It was, therefore, we think, wisely determined on the part of the officers of the Society not to resort to such an expedient, which, had the day proved less sunny than it was, would have inevitably caused too great an amount of shade.

The stove and greenhouse plants which were shown in the first four classes afforded of themselves a noble display; and in several instances the collections were so nearly balanced in point of merit, that the Judges must have had a most difficult task to decide which were the best.

In Class 1, for fifteen Stove and Greenhouse Plants, a first prize was taken by Mr. Peed, gardener to Mrs. Tredwell, Lower Norwood, with *Allamanda cathartica* and *grandiflora*, *Eriostemon nerifolium*, *Ixora alba* and *coccinea*, *Polygala acuminata*, a very large and fine *Erica Cavendishii*, *Tetrastemon ericæfolia*, *Chorozema Lawrencianum*, *Aphelexis sesamoides superba* and *macrantha purpurea*, *Pimelea spectabilis*, and *Azaleas Criterion* and *Murrayana*. All the above were handsomely grown, and some were of very large size. The second prize was awarded to Mr. Green, gardener to Sir E. Antrobus, Cheam, for a collection likewise of great merit, but some of the plants had lost their freshness from having been at the Crystal Palace. In addition to some of those already named, he had *Rhododendron Gibsoni*, *Dracophyllum gracile*, *Aphelexis macrantha rosea* (very fine), *Franciscea calycina*, *Pimelea Hendersoni*, a large *Eriostemon intermedium*, *Hedera macrostegium*, and *Azaleas Præstantissima* and *Juliana*. Mr. Baxendine, gardener to W. H. Smallpiece, Esq., Guildford, received a third prize, his collection, it is almost superfluous to state, being likewise excellent. It included a fine bushy *Rhynchospermum jasminoides*, *Aphelexis humilis rosea* and *macrantha purpurea*, *Iveryana Azalea*, and the double pink *Glory of Sunninghill*, *Stephanotis floribunda* (some of the flowers, however, looking rather dingy), a fine bushy *Erica depressa nana*, a large and fine *Erica Cavendishii*, *Boronia Drummondii* and *microphylla*, a fine *Coleonema rubra*, *Statice brassicæfolia*, *Chorozema Henchmanni* (beautifully covered with bloom), *Epacris heteronema*, and *Pimelea mirabilis*. Mr. Rhodes, who received a fourth prize, had among other specimens a fine *Phænocoma prolifera* in full bloom, a large *Erica Cavendishii*, *Hardenbergia monophylla*, *Chorozema cordatum*, and a fine *Erica coccinea minor*.

Class 2 was for twelve plants for nurserymen only, and here Messrs. Fraser, of Lea Bridge, were first. They had the fine

blue *Leschenaultia biloba major*, *intermedia* of the same genus, *Clerodendron Kämpferi* with its showy scarlet flowers, a large and very fine *Erica coccinea minor*, *Adenandra fragrans*, *Boronia serrulata*, and *Eriostemon buxifolium*; but the two *Azaleas Gledstanesii formosa* and *variegata* were anything but good, whilst the *Polygala* at the back appeared to be either past its best, or else was suffering from want of water.

Messrs. Lee, of Hammersmith, came second, with some very good plants, among which were *Phænocoma prolifera*, not fully out; a large *Erica Cavendishii*, a *Heath* which is deservedly a favourite with all exhibitors; *Allamanda grandiflora*; a nice bush of *Leschenaultia formosa*; *Adenandra speciosa*; *Hedera tulipiferum*; *Erica tricolor Wilsoni*; a small *Aphelexis macrantha*; *Pimelea Hendersoni superba*, and *Allamanda grandiflora*, with several of its large showy yellow flowers.

Mr. Cutbush, of Barnet, received a third prize for a collection in which were *Coleonema rubra* and *tenuifolia*, *Hypocolymma robustum*, and *Phænocoma Barnesii*. Messrs. Jackson & Son had fourth for an evenly-grown collection, containing *Clerodendron Thomsonæ*, *Labichea heterophylla*, a fine plant of the pretty *Erica ventricosa tumida*, a beautiful *Pleroma elegans*, &c.

In Class 3, for nine plants, Mr. Chilman, gardener to Mrs. Smith, Ashted House, Epsom, came in first, all the specimens being finely grown. They consisted of *Erica Cavendishii*, *Hedera tulipiferum* and *macrostegium*, *Aphelexis spectabilis grandiflora* and *macrantha rosea* (both fine, but the latter particularly so), a large *Acrophyllum venosum*, *Polygala Dalmaiziana*, *Pimelea Hendersoni* and *Franciscea confertifolia*, some of the bloom of the last rather spoilt.

Mr. Kaile, gardener to Earl Lovelace, came second with a handsome *Chorozema Lawrencianum*, a nice *Rhynchospermum jasminoides*, *Epacris miniata grandiflora*, and other plants already named.

Class 4 was for collections of six, and here Mr. Ingram, gardener to J. J. Blandy, Esq., Reading, was first with some very nice plants, the most striking, however, being *Aphelexis macrantha rosea* (which was a beautiful mass of flowers), and *Pimelea spectabilis*. Besides these there were a good *Stephanotis*, *Statice brassicæfolia*, *Hedera tulipiferum*, and *Erica Cavendishii*. Mr. Page, who obtained the second prize, had fine specimens of *Pimelea decussata*, *Hedera tulipiferum*, *Allamanda Schottii*, and a large *Erica Cavendishii*.

Mr. Smith, gardener to A. Henderson, Esq., Norwood Grove, was third. He had a fine *Hoya bella*, also a very good *Rhynchospermum jasminoides*.

Extra prizes were awarded to Mr. Penny, gardener to H. H. Gibbs, Esq., Regent's Park; Mr. J. Tegg, gardener to Baron Hambro', Roehampton; and to Mr. Wheeler, of Stamford Hill.

Among the Orchids were some magnificent examples of these gorgeous flowers, those from Messrs. Veitch being by far the finest, and, as might be expected, displayed to the best advantage, principally in large pans as unobtrusive as regards colour as possible. We wish we could say the same as regards the other collections, some of which were set up with little or no regard to effect; and in one, which was not only decidedly bad in this respect, the plants were in ugly tubs, or rather pails, with open sides, and by way of still further displaying the taste of the exhibitor, they were painted red. Another exhibitor used perforated covers over the pots and of similar materials to these, but quite new and clean; and they too were open to the objection that the eye would rest upon them and not on the plants. Such contrivances, so far as we know, serve no useful purpose, and afford an excellent harbour for insects, which at all times are sufficiently troublesome without being encouraged. Where the object is to display plants to the best advantage the quieter and more unobtrusive the colour of the pot or other utensil that contains them the better. Paint and varnish can add nothing to the beauty of the flowers, and when associated with these almost invariably displease.

Class 5 was for twenty Orchids. In this Mr. Milford, gardener to E. McMorland, Esq., Haverstock Hill, was first, having *Phalænopsis grandiflora*; *Cattleya lobata*, *Mossia*, and the beautiful variety of the latter called *aurantiaca*, in which the lip is stained with orange towards the edges; *Lælia purpurata splendens*, *elegans*, and *Bryasiana*, all of them splendid flowers, the last in particular; *Cypripedium barbatum superbum* and *villosum*; *Erises crispum*, *Fieldingii*, and *Larpenæ*; *Saccolabium curvifolium*; *Odontoglossum nævium* and *Phalænopsis*; also the dusky *Epidendrum nigro-roseum*, *Lælia grandis*, and *Vanda*.

tricolor *superba*. This collection from the beauty as well as great value of the subjects shown well deserved the first place.

Mr. Baker, gardener to A. Bassett, Esq., Stamford Hill, came next, and his collection was also of great merit, containing several beautiful examples, of which the following are a few—*Cattleya Mossiae*, *Vanda suavis*, *Dendrobium macrophyllum giganteum*, with three immense spikes, the curiously-spotted *Cypripedium Lowii*, from Borneo; *Lælia cinnabarina* and *purpurata*, *Cypripedium barbatum superbum*, *Anguloa Clowesii*, the red-flowered *Saccolabium curvifolium retusum*, and others, together with *Ærides* and *Oncidiums*.

Mr. Bullen, gardener to A. Turner, Esq., Leicester, came third, and had the same plants as exhibited at the Regent's Park and Crystal Palace. Among them were some fine *Ærides* and *Vandas*, together with *Orchis foliolosa*, &c. Mr. Peed was fourth.

In the Nurserymen's Class, 6, for twelve Orchids, Messrs. Veitch were first with a *Phalænopsis grandiflora*, with magnificent spikes of its large pure white flowers; *Cattleya Mossiae*; *Saccolabium guttatum major*, of which there were twelve fine spikes; *Cypripedium barbatum superbum*; a very large *Vanda tricolor*; *Vanda suavis*; *Calanthe veratrifolia*; *Ærides Larpentæ* and *Fieldingii*; *Odontoglossum Pescatorei*; *Chysis Limminghi*, and *Lælia purpurata major*, with eleven flowers. Mr. Woolley, of Cheshunt, was second, having also a nice collection.

Class 7 was for ten Orchids, and here Mr. Penny obtained the first prize. He exhibited *Cælogyne Lowii*, *Anguloa Ruckeri*, *Vanda suavis*, and good examples of other species already named. Mr. Page, who was second, had *Dendrobium formosum giganteum*, with its large white and yellow rhododendron-like flowers; the charming *Ærides Lobbi*, *Saccolabium retusum*, &c.; and Mr. Green and Mr. Chilman were likewise successful competitors.

In Class 8, for six Orchids, Mr. Wiggins, of Isleworth, had *Oncidium Lanceanum*; Mr. Smith, of Syon House, *Lycaste aromatica*, and a fine *Dendrobium nobile*; and Mr. Wheeler *Oncidium altissimum* with a very long spike of bloom. Mr. Wiggins had a first prize, the others stood second and third.

Decidedly the most brilliant feature of the Show were the Azaleas, which were immense masses of bloom, such as no one who has not seen the specimens which are exhibited at the metropolitan shows could believe it possible to produce. But on this occasion even persons who had been accustomed for years to exhibitions, expressed their surprise and unqualified admiration at the plants shown by Mr. Turner, Messrs. Veitch, and Mr. Green.

Mr. Turner, who showed the finest plants, had *Arborea purpurea*, a beautiful purple mauve; *Chelsoni*, *Glory of Sunninghill*, *Extranei*, *Criterion*, *Juliana*, *Iveryana*, *Murrayana*, and *Alba Magna*. These could not be less than 5 or 6 feet high, and were certainly from 4 to 5 feet through. They were finely grown, and so densely covered with flowers that scarcely a leaf was to be seen.

Messrs. Veitch who were second, had also magnificent plants, scarcely yielding to those from Mr. Turner. They consisted of *Magnificent*; *Extranei*; *Broughtoni*, very fine; *Perfecta elegans*, deep scarlet; *Mrs. Fry*, bright crimson; *Criterion*; *Trotteriana*; *Erquista*; and *Triumphans*, rosy crimson, large and fine.

Messrs. Fraser received a third prize for some nice pyramids, among which were *Holfordi*, rosy purple; *Lateritia*; and other sorts already named, but none of the plants nearly approached in size and beauty to the two collections above referred to.

Mr. Turner also exhibited several very fine plants in the Miscellaneous Class.

In the Amateurs' Class for nine, Mr. Green carried all before him, and though his specimens were not so large as Mr. Turner's, they were remarkably fine, being densely covered with bloom. One in particular, *Coronata*, which was placed at the corner where the nave and principal passage from the gardens intersected, was a perfect pyramid of rosy red, forming a glowing object even when viewed from a long way off. Among the others were the fine yellow *Sinensis*, *Perryana*, *Iveryana*, *Symmetry*, *Glory of Sunninghill*, and *Sir Charles Napier*. The second prize fell to Mr. Page, who had *Compacta*, small, but very densely covered with bloom, and good plants of *Juliana*, *Criterion*, and *Optima*. Prizes were also awarded to Mr. Lavey and Mr. Peed.

Class 11 was for six kinds; in this Mr. Penny was first, with *Madame Mieliez*, white, somewhat striped with rose; *Frostii*, *Juliana*, *Duke of Devonshire*, *Model*, and *Criterion*. Mr. A. Ingram, of Reading, had a third, and Mr. Wheeler a fourth prize, extra ones being also given to Mr. Lavey, Mr. Chilman, and Mr. Kaile.

Of *Rhododendrons*, which were shown in Class 12, only one collection was exhibited—that from Mr. C. Noble, of Bagshot. It consisted of *The Sentinel*, dark rosy purple; *The Princess*, white; *The General*, rosy purple; *Princess Alexandra*, deep rose, with dark spots; *Snowball*, white tinged with lilac; and *The Prince*, with a fine large truss of deep rosy crimson.

Prizes were offered for the best group of plants, showing effective arrangement for decorating a small conservatory, and for these there were several competitors. Mr. Turner obtained the highest award, Messrs. Veitch and Messrs. Lee being second and third. Mr. Turner's arrangement consisted of a compact mass, chiefly of flowering plants, with tall *Azaleas* at the back, and there appeared to be too small a proportion of graceful-foliaged plants. The arrangement of Messrs. Veitch and Lee afforded room to pass among the plants; and in the former flower and Fern stands were introduced, forming a nicely-balanced design, whilst Messrs. Lee had a vase and pedestal in front, round which a space was left to walk in, and beyond this the plants were ranged in three sides of a square, with the angles taken off. The other competitors were Mr. Bull, Messrs. A. Henderson & Co., and Mr. Shenton, of Hendon.

In the remaining classes there were several very fine exhibitions, particularly of *Roses* in pots, and *Pelargoniums*; but these it will fall to other hands to describe, while the subjects brought before the Floral and Fruit Committees will be noticed in our report of the proceedings of these bodies.

In the eastern arcades, besides the implements, &c., which have remained there since previous shows, some fresh ones made their appearance. Mr. Clarke, of Brackley, had his new and extremely light iron-handled scythe, so favourably reported on in our last issue; Mr. Read, of Regent's Circus, his excellent garden syringes, also tub engines, and a very efficient pail engine; Messrs. Warner, pumps, garden engines, and syringes, included among which were a double-action garden syringe, and an American garden engine apparently on the same principle. Messrs. Roshier exhibited garden edging-tiles. Flower-baskets, garden chairs, &c., of wirework came from Mr. Watts, of Brompton; and a model of a greenhouse with a double glass roof and sides, from Mr. H. Barnwell, of Colney Hatch. It is claimed for this that it possesses the advantages of economising fuel and preventing scorching, the confined air being a non-conductor of heat. Air is admitted both into the house and between the double glass by ventilators at the bottom.

POTTING HEATHS AND AZALEAS.

"ELIZABETH" deserves a most courteous answer were it for nothing else than her letter of inquiry being a model of what such a letter should be. Here it is as an example to those who, after a page or two, still leave us in a kind of maze as to the information they really want:—

"Elizabeth will be obliged by being informed if it is requisite to fresh-pot Heaths and Azaleas every year, and what time it requires to be done? Also the proper soil for each plant?"

Here are three questions in just as many lines. Well, then, the best soil for Heaths and Azaleas is heath soil—that is, soil composed chiefly of decayed vegetable matter mixed with the worn-down and disintegrated pieces of stone and rock, such as is to be found on elevated ground where Heath naturally flourishes. This differs in all its properties from what is usually called peat bog—such as the peats used for fuel—as that is always composed of vegetable matter more or less decomposed, but under water; and not, therefore, like heath soil, exposed to the sweet breezes of the atmosphere. This heath soil, if not naturally sandy, should have a little silver sand mixed with it. The soil itself should be a little rough rather than dust-fine. For instance, in a four-inch pot, a good part of the soil should be in bits like peas; for a six-inch pot a good portion should be in pieces like the size of field beans; and for an eight-inch pot a number of pieces should be as large as walnuts. Drainage should also be well secured, and the potting should be done firm. When plants get large and established, so as to need a large pot, say 10 or 12 inches in diameter, a little fibry loam may be used along with the heath soil; but in the case of young plants it will be best to keep to the heath soil. A few bits of charcoal for drainage will be an advantage, and some small pieces like small peas among the soil will help to keep it sweet and open.

Now as to the time of potting. Other things being suitable, the best time for potting is early enough in spring and summer,

for the roots to be pretty well established in the new soil before winter comes. In the case of Azaleas, the best time for potting is when the plant has finished flowering, and when after clearing away all seed-vessels and old flowers, the plants are growing afresh under the treatment shortly described in "Doings of the Last Week" a week ago. Much the same rule must be followed with Heaths, only not so much closeness and a moist atmosphere should be given them for fear of inducing the presence of mildew. All plants are the better of being kept a little closer—that is, with less air—after being potted; and, in addition to watering the roots, the top should frequently be syringed, and the leaves shaded from very bright sunshine, until the roots are working freely in the fresh soil.

Then, thirdly, as to the necessity for repotting every year. As a general rule, we may say that plants in small pots are the better for this repotting; but when the plants are in six or eight-inch pots they will often be better of going on a season or two without potting, and when they are in twelve-inch pots or larger they will be all the better for not being turned out for two or three years, if the drainage is right; but instead a little of the surface soil is removed with a small pointed stick, and fresh surfacings added, and with that, in the case of Azaleas, a small portion of very rotten old cowdung may be incorporated.

FLORISTS' FLOWERS AT THE CRYSTAL PALACE SHOW.—MAY 23RD.

NEVER did the beauties of the Crystal Palace, or the excellence of its Shows, appear to me in such strong relief as they did on Saturday last. It may have been that my recollections of the French "Exposition" were still in my mind and the grandeur of the display was by comparison more than ever manifested; or else that the Show was really finer than it has ever been, but certainly it would be impossible to exaggerate the excellence and high character of very nearly everything that was contributed to the floral display. A few youthful exhibitors (their youth applying only, so far as I know, to their exhibition years), did certainly bring some things which they had much better have left at home; but they were only slight blemishes in what was a most magnificent sight. All down that immense nave on either side rows of magnificent greenhouse plants, fragrant and curious Orchids, delicate Roses and dazzling Pelargoniums, displayed to thousands of admiring eyes their rare and singular beauties. All the classes were well represented, and in many the competition ran so close that it was with great difficulty the Judges were able to decide on their merits; while many new and curious plants attracted, as novelty ever does, many to behold and scrutinise their beauties. As others have entered upon the description of stove and greenhouse plants and fruits, I will endeavour to give an idea of the florists' flowers, whether in pots or as cut blooms, although I do not attempt the Azaleas, which in truth are as much a florists' flower as the Pelargoniums.

Roses in pots were not, I think, so fine as I have seen them, although some individual plants were magnificent. My own taste inclines to the smaller-sized plant rather than to those monstrously overgrown productions; but taking them as generally admired, nothing could possibly be finer than the plant of *Souvenir d'un Ami* and *Charles Lawson* in Messrs. Lane's collection, or the *Lælia* of Mr. Wm. Paul. So close was the contest here that the Judges placed the two collections as equal firsts. Messrs. Lane's plants were *Paul Perras*, *Comtesse Mole*, *Souvenir d'un Ami*, *Louise Peyronney*, *Baronne Prevost*, *Charles Lawson*, *La Reine*, *Lamarque* (not good), *Chénédoilé*, and *Paul Ricaut*. Mr. Paul's contained *Général Jacqueminot*, *Madame Willermoz*, *Louise Odier*, *Paul Ricaut*, *Souvenir d'un Ami*, *Souvenir de la Malmaison*, *Paul Perras*, *Lælia*, *Baronne Prevost*, and *Charles Lawson*. Messrs. Paul & Son were third with smaller plants, and *Paul Perras*, *Chénédoilé*, *Madame de St. Joseph*, *Juno*, *Souvenir d'un Ami*, *Coupe d'Hébé*, *Niphotos*, *Madame Boll*, *Charles Lawson*, and *Paul Ricaut*.

The Roses in eight-inch pots were in my estimation far prettier, and nothing could be better done than Mr. Turner's collection, which gained the first prize. It contained *Baronne Prevost*; *Madame Damazin*, *Tea*; *La Reine*; *Dr. Bretonneau*; *Madame Charles Wood*, a fine Rose; *Madame Boll*; *Madame Bravy*, *Tea*; *Modèle de Perfection*, quite a gem; *Catherine Guillot*; and *President*, *Tea*. Mr. Wm. Paul was second with *l'Elegante* (poor), *Triomphe de Paris*, *Baron Gonella*, *Madame Furtado*,

Buffon, *Senateur Vaisse* (good), *Alphonse Karr*, *Comtesse Orvaroff* (Tea), *Beauty of Waltham* (fine), and *Louis Guelina*. We thus find Mr. Turner comparatively a young grower, taking, as is his custom when he attempts anything, the first place.

I have never seen a closer run—a neck-in-neck race, in fact—than the contest in 10 Pelargoniums open to amateurs and growers. It was at last decided for Mr. Bailey, of *Shardeloc*, who won it with Mr. Marnock, *Monarch*, *Desdemona*, *Rose Celestial*, *Scarlet Floribunda*, *Sir C. Campbell*, *Sanspareil*, *Lady Canning*, *The Belle*, and *Ariel* (they were thus placed). Mr. Turner was second with *Beadsman*, *Rose Celestial*, *Desdemona*, *Bacchan*, *Fairest of the Fair*, *Empress Eugénie*, *Etna*, *Festus*, *Guillaume Severyns*, *Candidate*. Messrs. J. & J. Fraser were third with *Desdemona*, *Sanspareil*, *Governor-General*, *Rose Celestial*, *Fairest of the Fair*, Mr. Marnock, *Sir C. Campbell*, *The Bride*, *Candidate*, *Pizarro*. I have written them as they were staged, and it will be seen how effect has been arrived at by judicious arrangement. I rather fancied that in Mr. Turner's lot *Beadsman* and *Rose Celestial* were too close to one another, although one hardly dares to find fault with so excellent an arranger of colours as he is. It would be needless to point out excellencies where all were good, but we cannot forbear saying that the *Lady Canning* of Mr. Bailey was the best plant there, and a perfect gem. In the class for Amateurs Mr. Shrimpton, gardener to J. Smith, Esq., *Mickleham Hall*, was the only exhibitor. His plants were *Vestal*, *Governor-General*, *Rose Celestial*, *Sanspareil*, *Fairest of the Fair*, and *Peacock* (a very fine and striking plant).

Fancy Pelargoniums were also well shown, and in considerable numbers; Mr. Turner exhibiting two collections, one of which obtained first and the other second prize. His first collection contained *Clemanthe*, *Acme*, *Arabella Goddard*, *Lady Craven*, *Delicatum*, and *Roi des Fantaisies*. Messrs. Fraser were a good second with *Acme*, *Clara Novello*, *Cloth of Silver*, *Queen of the Valley*, and *Celestial*. Mr. Turner's smaller plants were *Queen of the Valley*, *Cloth of Silver*, *Ellen Beck* (a decided beat on *Celestial*), *Reliance*, *Undine* (very bright and beautiful), and *Modestum*. Mr. Bailey was fourth with *Acme*, *Rosabella*, *Lady of the Lake*, *Negro*, *Lady Craven*, and *Clara Novello*. There was a want of freshness here which militated against them, but the plants were good.

A good number of seedling Pelargoniums were exhibited, the most noticeable of which were *Diadem*, a very fine rosy purple, from Mr. Hoyle, a flower of great size and substance, and perfectly circular: this obtained first prize. The second was *Artist*, another fine flower of a warm rosy tint. *Alexandra* was third, a bright lively flower in the way of *Belle*, but better; *The Prince* fourth. These were all Mr. Hoyle's flowers. There were *Orion* also, a bright scarlet, *Eurydice*, *Cynosure*, *Pelides*, *Royal Bride*, &c.

I have never seen such fine plants of herbaceous Calceolarias as those exhibited by Mr. James, gardener to J. Watson, Esq., *Isleworth*. His collections were placed first and second; but I think it is a mistake not to define what the Calceolarias are to be, as shrubby and herbaceous were mixed together. His most noticeable plants were *Lord Clyde*, dark; *Macaroni*, dark red spotted; *Master Watson*, cherry crimson with spots; *Lord Elgin*; *Colonel Massy*; and *Mr. Davies*. Mr. Reid, gardener to J. N. Farquahson, Esq., *Sydenham*, was third; but his plants were mostly shabby, and were not sufficiently in bloom.

In CUT FLOWERS, Tulips must be placed first, although the day was somewhat late for them, and as a consequence some of the blooms were too fully expanded. This prevented Mr. Turner's stand from taking first place, to which it was otherwise entitled. As many as seven collections were staged; but some people have strange notions as to what are required for exhibition, for we saw a yellow self and various most foul cups in some of the stands. Mr. Hunt, of High Wycombe, took first prize with *Magnum Bonum*, *Anastasia*, *Maid of Orleans*, *Royal Sovereign*, *Gari-baldi* (seedling), seedling *Polyphemus*, *Gen. Baneveld*, *Madonna Storey's Queen*, *Duchess of Sutherland*, *Vivid*, *Romeo*, *Triomphe Royale*, *Victoria Regina*, *Duchess of Sutherland* (Gibbons), *Blomart*, *George Heywood* (a magnificent bloom), *Heroine*, *Pandora*, *Lady Downes*, and *Lord Denman*. Amongst Mr. Turner's were fine specimens of a bizarre seedling, a very noble flower, and *Duchess of Sutherland*, *Triomphe Royale*, *Duke of Clarence*, *Magnificent*, *Maid of Orleans*, and *Dr. Horner*.

"Well done, Warwickshire!" I may say as to *Verbenas*. *Bagby* and *Coventry* both show us that they can do something besides play football and make ribbons; for Mr. Treen and Mr. Perkins carry off the laurels here, being in fact the only exhibitors. Why

this should be, ye metropolitan growers ought to ask. But I believe it would require something to beat the stands exhibited that day. Mr. Treen, who took both first and second, had Magnificent, Foxhunter, Rugby Hero (a very fine flower), Snowflake, Géant des Batailles, Apollo, Firefly, Great Eastern, La Gloire, Mrs. Harrison, Nemesis, Decorator, Venus, Julie, Miss Field, Auricula, Lord Raglan, Mrs. Moore, Kate, Rainbow, Mrs. Pennington, Kenilworth, and Countess of Aylesford. Some of these were really splendid, and reflected great credit on the growers. Mr. Perkins had also some excellent blooms: amongst which I was glad to see that Lord Leigh maintained its position.

No less than thirteen stands of Pansies were set up, including several of Fancies from Messrs. Downie, Laird, & Laing. The first prize was obtained by them, and contained General Young, Attraction, Prince of Prussia (seedling, yellow ground), Mary Lamb, Francis Low, Jenny Lind, Lord Clyde, Mrs. Laird, Imperial Prince, Cupid, Countess of Rosslyn, Sir J. Graham, Lady Burn, Beauty, Thomas Martin, C. W. Ramsay, Mrs. Hopkins (very smooth), Eclat, Perfection, Alice Downie, and Masterpiece, very fine. Amongst Seedling Pansies were two curious Fancies—Mr. Nethercote, dark claret, edged with a light border all round; and Earl of Rosslyn, a curious dark clarety flower.

There were two collections of Cut Roses from Messrs. Paul and Son and Mr. Wm. Paul. Amongst the former I noticed La Boule d'Or, very good; Louise Chaix; François Lacharme, a splendid flower; Madame Furtado; Eugène Appert; Madame Charles Wood; Alphonse Damazin, very full; Souvenir de Comte Cavour; and a box of yellow Tea and Noisette, containing Louise de Savoie, Marquise de Foucault, Safrano, Solfatarre, Viscomtesse de Cazes, and Madame William. In Mr. W. Paul's collection I saw Monte Christo, Souvenir de Lady Eardly, both good; Beauty of Waltham, and Admiral Gravina, a dark and good flower.

I cannot pass by the nice strain of new Mimulus exhibited by Mr. Bull, nor the two fine Clematises of Mr. Standish, and the white Azalea, Louise Von Baden, of Mr. Turner.

I must now finish, as my space is fully occupied, but cannot do so without saying what indeed is unnecessary almost of the Palace, that everything was done to promote the comfort and pleasure of the exhibitors and visitors, and that Mr. Houghton may fairly be congratulated on the high position to which under his judicious and excellent management the Crystal Palace Flower Shows have attained.—D., Deal.

SHIFTING PLUM TREES WITH FRUIT ON THEM.

I HAVE some Plum trees in pots which promise to produce heavy crops this year. The pots the trees are in are rather small for them, and their foliage is very scant. My gardener proposes to shift them into larger pots now. Would this be proper treatment?—AN IRISH SUBSCRIBER.

[If the trees could be moved without at all disturbing the roots no harm to them would arise, but we do not think there is any necessity of running the risk. We should prefer removing the surface soil, and replacing it with well-decomposed stable-manure. This, combined with weak liquid manure, would sustain the growth of the trees as well as of the crop. Do not allow any tree to be overloaded; thin without mercy; and a good rule is, when you think you have thinned sufficiently, then to take off half of the fruit you have left. The vigour of the tree and the size and flavour of the fruit depend upon a judicious thinning of the crop.]

RHODODENDRONS.

I CONFESS entering on the subject of Rhododendrons more with a view to the encouragement of some other of your correspondents to record their opinions on the matter than with any expectation of throwing much light on their cultivation myself, for it is now some years since I was amongst them, where they might be said to be fairly at home. We have some here, and, in fact, most places of note have their Rhododendron-beds; yet it is only in places possessing a soil adapted to them that they grow with that freedom which indicates that they are quite at home.

Beds artificially made will afford for a time a certain amount

of success; but even then the plants seldom do so well as when the natural soil of the district suits them; and although I am far from assuming to myself the credit of being perfectly right in my views of their habits and requirements, I should say that a soil in which they will grow and prosper and perfect their seed, and where that seed sows itself and produces plants amongst the wild rubbish by which they are surrounded, is the soil adapted to the Rhododendron. But there is even great diversity in soils of this kind; and moisture, which exercises so powerful an influence on certain plants, either by contributing to their success or by causing their extinction, is certainly not the all-powerful agent here, for I have seen scores of acres of Rhododendrons occupying the crest and sides of a dry peaty hill with some stunted Birches overtopping them; while in another place the plant is seen occupying a wet springy dell, not a stagnant swamp, but receiving large quantities of spring water in its descent to the basin below. Colour and texture of the soil are likewise not much of a criterion, for on a dry hilly situation in the grounds at Linton Park, Rhododendrons flourish and ripen their seeds, and occasional plants are found a good distance off. Doubtless, there might be more, only the scythe is apt to destroy them. This soil is a sort of yellow friable loam, with at least three-fourths stones, with rock underneath—standing water at not less than 90 or 100 feet from the surface. I may add, that the kinds planted are common hardy ones, not all the old ponticum, but such as were esteemed useful and good some twenty-five years ago.

I will adduce another case. At Preston Hall, only a few miles from here, a rounded hill of dry sand, previously a coppice of Hazel, Birch, and other trees, apparently self-sown, was cleared, all but some large Scotch Fir trees, and a summer-house was erected on the summit. The space having been formed into a half-dressed pleasure-ground, with rockwork and other rustic appendages, Rhododendrons and similar plants were introduced on a large scale. The eastern side of the mound, or hill, for it was of considerable elevation, was planted some three or four years before the western side, the soil being a sort of pale yellow sand without a stone, and to all appearance all sides of the hill were alike; but, strange to say, the plants on the eastern side, though they grew vigorously and flowered well, did not perfect their seeds so as to produce young plants by self-sowing; while on the western side it is not too much to say these were growing by millions. Self-sown Groundsel on the best quarter of the kitchen garden could not have come up thicker; and when I saw them in the spring of the present year they were in a nice condition to transplant, having some half a dozen leaves each, and being sturdy and well rooted.

Now, the question arises, Why did not the eastern side of the hill produce plants as well as the west side, the soil being alike in both cases, and the varieties much the same? The attention or rather non-attention, for they did not require much care in the summer months, was the same in both places, and the plants, so far as related to their general healthiness and freedom in flowering, were also alike. Mr. Frost, the very able gardener there, was at a loss to account for the above circumstances. I might also add that Andromedas looked remarkably well, as likewise did some of the Azaleas. Kalmias were not so satisfactory. Amongst the Rhododendrons were many new and valuable kinds which promised to vie with the commoner ones in robustness and well-doing. I believe some peat was added to the natural soil, or sand for some of the choicer kinds; but it was evident such assistance was not wanted for the ordinary ones.

Taking a view of the same plant in other counties, I think the largest specimens I have ever seen were in Lancashire, where a rich, black, sandy soil, well adapted for all root crops, seemed also to suit the Rhododendron. In northern Cheshire the Rhododendron is likewise at home; while on the steep hill sides of some places in Staffordshire and Derbyshire, it is evidently harder than the common Laurel. At Alton Towers, I was told it sowed itself and reproduced a numerous offspring on a soil differing considerably from those I have previously described. At Chatsworth it is also extensively planted on soils and in positions differing widely from each other in character; but I had not an opportunity when there of observing all, and I have been told that there are stations in Wales where it thrives better than anywhere, but I am not acquainted with them. It seemed to thrive pretty well in Cornwall, though what I saw was not so good as I have seen in less favoured localities; Mr. Pooley, the gardener at Mount Edgecumbe, pointed out to me the positions in which it prospered, and those in which it would not do so in

their grounds, the line of demarcation being a perceptible change of soil, visible enough to the naked eye, and, doubtless, widely different in its chemical constituents. Some other places might be pointed out possessing similar features to the examples above cited, and many other instances of successful cultivation might be given, but it would be tedious to do so.

Those who wish to see a large number of Rhododendrons all in flower at one time ought to visit Cobham Hall, near Gravesend, where I believe Lord Darnley kindly permits the public on certain days to see them. I should think the mass of plants if collected would cover fifty acres or more. They occupy the crest and sides of some dry peaty hills, a few Birch and other trees being intermixed with them, and walks or drives running in various directions carry the visitor through a whole sea of flowers; while the wild beauty of the Foxglove profusely rising in all directions is scarcely less striking. Here it is needless to say that the Rhododendron sows and reproduces itself to any extent; and I believe the bulk of the plantation to have come from seed, a previous occupier of Cobham having planted the original in a soil in which they soon became naturalised, the result being a complete cover of them. Sites differing widely from this may occasionally be found where they do tolerably well. Even in clay they will grow, but are not at home; but I have seen them do tolerably on the edge of a peaty morass. The condition here that supported them against the undue moisture was the mineral qualities of the water, and not its superabundance.

The above examples of successful cultivation might be indefinitely extended, and the various nurseries where large quantities of plants are raised for sale might be named; but it is needless following the matter further than saying that most districts possess a spot suitable to the growth of this plant. The diversity of soil with which this country is favoured often exhibits strata of widely different kinds in close proximity to each other. I remember once noticing a black peaty morass, said to be 30 feet deep, over which a turnpike road was laid, which vibrated very considerably every time a load passed over it, and yet on the very edge of this morass was a freestone quarry some 60 feet or more high, and supposed to descend as deep as the morass, the soil on the top of the quarry being ordinary loam mixed with yellow sandstone shatter at the top. A peaty soil is also sometimes found near chalk, and it not unfrequently happens that the soil which overlies the chalk is of a kind not at all unsuitable to Rhododendrons where there is plenty of it; and where the wild Heath grows there will the Rhododendron grow also. It must be understood that every black morass is not a suitable place. I have seen plants killed by being planted in such a material, and that not on the spot where it was found; for the marshy peat was carried to a distance, and to a certain extent deprived of some of its grosser qualities by the drier position it was placed in, yet it contained sufficient poisonous matter to kill plants that had previously been in good health.

Some little judgment is, therefore, required in selecting a proper place and a proper soil for the Rhododendron to grow in; for, though it is often found alike doing well in a damp position and in a dry one, in a shaded place and an open one, and in fact under circumstances that appear widely opposed to each other, there seems to be no question but that certain soils furnish the food it requires in greater abundance than others, and it is yet doubtful whether the plant relishes such food in a liquid form, or contrives to absorb it from the dry soil that possesses it. Besides, our knowledge of the chemical constituents of soils is not yet sufficiently good to point out at once the kind of food that will most likely suit it, or, rather, we are not sufficiently versed in the science of making compounds of such materials as are always at hand as will approach nearest to the natural soil in which the plant prospers best.

Rhododendrons are, however, often found thriving tolerably well in the rich black soils that have been long in cultivation, and also such plants may be seen struggling with a tolerable share of success in a damp clay. But this is an exception; they are more likely to prosper on the steep declivities of a rocky glen overhung by trees and surrounded by the wild herbage common to such places. Many other places might be pointed out where they seem to flourish, but it is unnecessary to follow out this subject further. We will, therefore, take a glance at the places where they will not succeed unless favoured in some way by artificial means.

Dealers in Rhododendrons not unfrequently tell us that they may be made to grow anywhere. This is true enough, and so

might Rice, the Sugar Cane, and many other plants; but is it prudent to attempt to grow them everywhere? In the case of Rhododendrons extensive importations of a soil of a suitable kind will induce a growth more or less healthy, according to the allowance given to each plant, and also the character of the soil or subsoil with which it is in contact. To lay peat on chalk or calcareous limestone is placing two substances together, the amalgamation of which rarely produces a good mixture. I remember once seeing a large heap of mortar made of lime and sand in the usual way, but the sand contained some mineral quality at variance with the lime, which, after lying about a year, and as the heap happened not to be wanted, completely destroyed the lime, or, as the labourer said, the sand had eaten the lime completely up. Now, lime or chalk will do the same with peat. Chalky situations are, therefore, seldom adapted to the Rhododendron, unless the surface soil be of the kind described above, producing the wild Heath naturally. Some sands impregnated with mineral matters of certain kinds are also unfit; and the same may be said of gravels, although some of the latter are amongst the best soils occasionally.

So difficult is it to describe what kinds of soil will do by any written description, and giving chemical analyses is of no use whatever to guide the judgment unless the soil to be decided on be subjected to a similar test, that I fear it is only by studying the herbage that a knowledge of the soil can be gained, and even this is not at all times to be depended on. It has been already stated that the wild Heath betokens a soil adapted to the Rhododendron, and the same may be said of Furze in many instances, but not in all. The wild Sorrel is often found in such soils. The Whortleberry also is often an accompaniment there, and Foxgloves likewise abound; but their robustness enables them to live in other places as well, so that without further proof their presence must not be taken as worth much. The same may be said of the Yew, which, though often found wild on heathy moors or woods, is quite as often found on chalky downs also, as is likewise the Juniper. Generally the Rhododendron and Birch thrive together. Where, therefore, the latter is found wild, the former may be planted. Several Ferns betoken a soil and situation suitable to the plant, and the presence of the little Stonecrop (*Sedum acre*) may also be regarded as indicating a medium, though not, perhaps, a situation suitable to the Rhododendron. Some other plants might be given as examples; but they are not always to be depended on, and are often found in situations of an opposite kind. I may as well, perhaps, say that such plants as Wild Thyme, Saintfoin, and several Vetches are often found on soils the very opposite to that wanted for the Rhododendron.

Of the various mixtures necessary to form a compound in which this plant will thrive tolerably well—I will not say particularly well—much might be said; and there is, perhaps, nothing in the gardening world as to which greater diversity of opinion exists. Unquestionably, dry peat cut with the Heath and other herbage on it, only a few inches thick and laid up just long enough to kill the herbage, is the best; but where this article has to be sought for some twenty miles or more, it cannot be used to the extent it would be if more plentiful; and though the best class of plants may be treated with it, it may be necessary to leave the less favoured ones to make shift with something else. The following mixture has been made use of here for some beds of Rhododendrons with a fair share of success, about a barrowload or less being used around each plant, all of which were small. It consists of such materials as are mostly to be had everywhere. In a timber yard large quantities of old bark, sawdust much decayed, and small chips in a similar stage of decay, were mixed with about an equal quantity of leaf mould well rotted. To this was added all the refuse of the potting-bench, omitting, of course, all sticky matter, but retaining all the sand and sandy soil and peat. With this were mixed several loads of white sand, such as was used for striking cuttings in and to mix with potting soils, and which I felt sure possessed no mineral matters hurtful to vegetable life. This mixture was well amalgamated, and turned several times and exposed as much as possible to the air before being used. Some hundreds of plants were planted in it, and so far they appear successful. The natural soil of the place was of various descriptions, some being a rather stiff loam, and some much less so, and what farmers would call good land. I will, however, at a future day report more on this. In all cases the planting of Rhododendrons on soils not adapted to them should not be done without some assistance in the way described: and amongst the many in-

redients to be had in most places, I would place sand as one of the most useful, especially such as is free of all noxious mineral matters, not, for instance, the green sand of West Devon and Cornwall, which is of so poisonous a nature as to kill vegetation. I think it contains copperas; but as all mineral poisons are bad, the sands in which these exist must be avoided. Generally river sand is good—not, of course, such as is within reach of the tide, but plain washed sand.

Of the situation for Rhododendrons it is hardly necessary to speak, as they are found doing well in full sunshine and in shade, on the highest hill and deepest valley, and on hill sides of all aspects, the hardest frost rarely injuring them; but a hot summer will affect them much if the soil be not one exactly adapted to their wants. They will, nevertheless, struggle for an existence amongst the rankest herbage, and contend against the roots of most trees that may claim a common share of the ground. In general, however, Elm-tree roots are the most hurtful to them; but it is more beneficial to have some slight covering to the ground than to let it be quite naked. When the latter is to be the case, to shade the ground from the sun, some artificial substance, such as leafy matter or short grass, moss, or litter of any kind may be used; for the small fibrous roots ramifying near the surface do not like to be scorched up with every blink of sunshine. Shading is better than watering, although the latter may be done also if it appears absolutely necessary.

To those about planting Rhododendrons in places not naturally adapted to them, and who do not intend treating them to wagonloads of their favourite peat, I would say, Obtain your plants from some nursery not possessing the soil best adapted to their vigorous growth; for by removing strong, luxuriant-growing plants from a situation of the very best kind to one of a medium or indifferent kind a check is given, and not unfrequently sickness follows. It is better, therefore, where other things favour doing so, to transfer plants from a poor place to a better one. Such as have been frequently moved and are, in a certain sense, naturalised to the second-class character of the soil they are to occupy, are more likely to do well there than those which are all at once transported from the best position to an inferior one.

On the many accompaniments to the Rhododendron-bed, it is needless to enter. Some growers advocate the vacant ground to be covered with Ivy, but this plant speedily outgrows and overpowers its legitimate neighbour. The variegated Vinca is better, and, perhaps, some summer annuals are better than either, as the Vinca gets strong. Whatever may be used, on no account allow the young growths of the Rhododendron to be meddled with, but rather confine the occupation of the ground to litter, moss, or short grass; and if the small birds do delight in scratching amongst such things and carrying part away, still there is plenty left to serve the purpose of a screen. On no account allow any digging or disturbing of the ground amongst old-established plants. If a little fresh surface be wanted, add some fresh material, for Rhododendrons will struggle better against the wildest herbage than against the cruel amputations of the spade. These matters and others of a like kind have, however, been frequently alluded to before in the columns of this paper.—J. R.

ROYAL HORTICULTURAL SOCIETY.

MAY 27.

FLORAL COMMITTEE.—On Wednesday the 27th, at the first great Exhibition of the Royal Horticultural Society, held at the Gardens, South Kensington, a Sub-Committee was appointed to report on such new plants and florists' flowers which were sent for examination. With the exception of the seedling Pelargoniums from Mr. Turner, Slough, and two new and beautiful Orchids from Messrs. Veitch, Chelsea, and Messrs. Low, Clapton, there were but few remarkable flowers, and, consequently, the certificates awarded were limited.

Among the plants, Mr. Standish sent a new and delicate white Weigela, which received a label of commendation; Acer sp., from Japan, with broad-lobed foliage, variegated with white spots and blotches—third-class certificate.

Messrs. Veitch exhibited *Dracophyllum* sp.—second-class certificate; *Eranthemum* sp., a dwarf trailing plant with handsome red-veined foliage, exhibited under a glass shade—second-class certificate; *Abies firma*, a handsome species of this tribe—first-class certificate; *Phalænopsis Lobbii*, a white flower with purplish

lip, but not equal to other varieties—second-class certificate; *Spiræa* sp., of dwarf habit with small rosy flowers, a very compact-growing plant—second-class certificate.

Messrs. Low, Clapton, exhibited *Dendrobium Parishii*, a small but very beautiful and interesting Orchid with purplish flowers, which was much admired—first-class certificate.

Mr. Williams, Holloway, sent an interesting variety of *Lastrea oreopteris*, with tasselled fronds—label of commendation.

Mr. Bull, Chelsea, exhibited *Areca dealbata*, a handsome plant with palm-like foliage—second-class certificate; *Caladium Lowii*—first-class certificate; *Pandanus elegantissimus*—second-class certificate; *Euonymus ovatus variegatus*—label of commendation; *Petunia Vernon*, one of the dark-veined varieties, very showy—label of commendation.

Mr. Ivery sent another of his numerous varieties of *Athyrium* named *Applebyanum*—label of commendation. Mr. Young, *Pandanus elegantissimus*—second-class certificate. M. Verschaffelt, Dieffenbachia *Verschaffeltii*, which received a label of commendation.

Mr. Turner, Slough, sent several seedling Pelargoniums. *Diadem* (Mr. Hoyle), a remarkably showy variety, perfect in form and new in colour, the back petals deep maroon margined with bright purplish-rose, pure white throat, lower petals banded with bright purplish-rose. This was decidedly the flower of the day, and was awarded a first-class certificate. *Pelargonium Artist* (Mr. Hoyle), a flower of the same good character as *Diadem*—back petals deep maroon margined with light rose, pure white throat, lower petals with a broad band of light rose; a striking variety, and remarkable for its softness and delicacy of colouring—first-class certificate. *Pelargonium Prince* (Mr. Hoyle), dark maroon upper petals, pure white throat, lower petals vivid, shaded scarlet—label of commendation. *Pelargonium Penelope* (Mr. Hoyle), a conspicuous flower, with dark back petals, clear white centre, lower petals shaded with rose, deeply blotched—label of commendation. *Pelargonium Prince of Wales* (Mr. Beck), upper petals deeply shaded with light rose margin, clear white centre, lower petals rosy carmine; a very pleasing variety—label of commendation. Mr. Turner exhibited many other seedlings of considerable merit, but too closely resembling other named varieties to receive special notice. Many other specimens were exhibited.

Mr. Standish again exhibited his Japan Clematises. The large double-flowering one now named *Fortunei* had eight or ten fine blossoms expanded. The purple single variety, *Standishii*, still maintains its character.

Mr. Bull sent a showy collection of *Pelargonium Zonale*; also a collection of *Petunias*, single and double. These plants were arranged in large baskets, and produced a pleasing effect. Mr. Bull exhibited other varieties of his hybrid *Mimulus*, which we have previously noticed. Seedling hybrids of the same *Mimulus* were also sent by Messrs. Henderson, Wellington Road; also a dwarf variegated *Pelargonium* of the scented-leaved family suitable for edgings. From Mr. Turner came a seedling *Verbena*; and from Mr. Laing, seedling *Pansies*. Many other specimens were sent of considerable interest, but too numerous to be noticed in this report.

Collections of newly-introduced plants that have received special recognition from the Floral Committee, 1860, 1861, 1862, were sent, and received certificates, thus proving the utility of this Committee. It was remarked by an old exhibitor, that out of the numerous plants and flowers placed before the Floral Committee, not one in twenty had failed in maintaining the character and merit assigned to it at these meetings, which is a strong guarantee for the public that the decision arrived at is generally correct, however inclined some persons may be to find fault.

FRUIT COMMITTEE.—In the department that pertains more particularly to the Fruit Committee, there were several exhibitions, the exhibitors evidently mistaking the work which is undertaken by the Committee on these occasions. It should be understood, that on the great shows and special general meetings, the only subjects that are expected to be submitted for the opinion of the Committee are only seedling or other new varieties of fruits and vegetables, and not such as come under no class in the Exhibition. Thus one sent a collection of six dishes of Apples, and labelled them "exhibited for the prize," when no prize was offered. Another sent a collection of vegetables which in early spring would have been reckoned meritorious, but which in the end of May did not possess any attractions.

The only two subjects that properly came under the notice of

the Committee were a seedling Strawberry from Mr. Turner, of Slough, called President; and a seedling Pine Apple from Mr. Stevenson, gardener to the Earl of Durham, Lambton Castle. The Strawberry President promises to be a variety of first-rate excellence; for although the fruit was, as a matter of course, at this season produced from forced plants, the flavour was so good as to warrant the belief that it will later in the season, and when produced from the open ground, be very much better. The fruit is large, varying from conical to cockscomb-shaped, and considerably furrowed. The skin is scarlet. When well grown we conceive it will be little if at all inferior in appearance to Sir Charles Napier, while the flavour is infinitely superior. The flesh is firm with a rich pine flavour, and with a pleasant briskness. Later in the season we hope to hear greater things of it.

The seedling Pine Apple of Mr. Stevenson is a very tall, conical-shaped fruit, of the colour and with the pip of the Montserrat, from which it was raised. Judging from the specimen exhibited, the shape is undesirable, from being so long and small. The flesh is not so solid as it might be, but is tender and though of excellent flavour is not superior to either the Queen or Montserrat. Mr. Stevenson, we believe, has still a large number of seedlings which we hope some day to see, and which we trust will prove of superior qualifications.

Mr. Challis, gardener to Lady Herbert, Wilton House, Salisbury, sent eight or ten fruit of a handsome-looking round-netted green Melon, which were all grown on the same plant, and hence called "Prolific;" but whether from the great crop or from the fruit being too long cut, it was deficient in flavour. It has all the properties of an excellent Melon, provided that particular point can be improved.

Mr. James Taylor, Hickleton, near Doncaster, sent a dish of good Figs; a large, oval, cream-coloured Melon, which was not in condition; and a brace of fine Cucumbers.

Mr. Drummond, gardener to Mrs. Allnutt, Clapham Common, sent a splendid basket of Mushrooms that elicited considerable notice.

Mr. Mobbs, gardener to W. B. P. Tyringham, Esq., Newport Pagnell, sent fruit of the seedling Apples exhibited at the last Meeting of the Committee; and Mr. Taylor, Temple Newsham, Leeds, sent two smooth-leaved Cayenne and one Black Prince Pines.

Mr. Barnwell, gardener to H. Mills, Esq., Bisterne Park, Ringwood, sent a collection of vegetables, and excellent dishes of Oscar and Keens' Seedling Strawberries, besides a collection of vegetables.

THE CONTROVERSY ON HEATING GLASS STRUCTURES.

I HAVE to thank Mr. Major, of Cromwell House, for his communication on the subject of heating hothouses described at page 330, as well as for his kind invitation to show me the mode in which it is done. I also beg to thank some other gentlemen for their communications on the same subject—even those who differ from me are equally entitled to my thanks, and I should have acknowledged their courtesies before but from unavoidable circumstances.

I am glad to see that a correspondent whose communication I quoted when I last wrote on the subject of "Hot Water *versus* Flues (or *vice versa*)," has replied to some queries made by Mr. Thomson on the cost of the flue, and the straightforward way in which he has done so leaves nothing for me to explain on the subject.

One thing, however, I would advocate in heating matters—whether by the flue or by hot water, it is best to have the job well done. I do not by that mean to recommend extravagant and costly workmanship, but simply work well and efficiently completed.

I have in a former chapter stated my views on the matter of heating, and need hardly repeat that when one house only is to be warmed—say sufficiently to keep out frost and maintain a temperature of 40°—it will, in most cases, be most economical to put up an ordinary flue; but when there is a series of houses to be heated, and in some of them a minimum of 60° is to be maintained, it is better in this case to adopt hot water. Mr. Thomson, however, has shown that the latter is not so expensive an affair, while "E." has shown that flue-heating is still much less. Without going into details, I expect that most parties who have

put up glass houses will have found the heating affair a much more expensive one than is shown in either of the communications. I have no doubt but both estimates are correct, but they may, nevertheless, be both below the actual cost of what other structures similarly planned were heated for.

Mr. Thomson assuredly must be wrong in affirming that hot-water pipes can be erected as cheaply as a flue; for one-half the expense of the latter must be included in that of hot water. The furnace-bars, door, and framework, as well as register-door and the chimney, must be the same in both, or, perhaps, the hot-water apparatus will require a somewhat more expensive one. Now, the remaining portion of the flue cannot assuredly cost so much as a boiler and the necessary quantity of piping.

I am sorry I cannot give the exact items of expenditure in an efficient hot-water apparatus; but I know of an instance in which upwards of £60 was paid for the apparatus required for heating a Pine-pit 85 feet long and 12 feet broad, and this sum did not include any part of the brickwork, or excavation, &c., for the fire-place.

Now, compare this with a flue-heated greenhouse here, in which the smoke travels along cement pipes of 12 inches diameter, and which have done duty for five years without any cleaning whatever. The cost of the pipes at first was 1s. 1d. per foot for Roman cement ones; and, I believe, 1s. 6d. per foot run for those of Portland cement, and they, being in thirty-inch lengths fitting together with very little trouble, merely rested on small brick foundations of 4½-inch work at the joints, the pipes being just clear of the ground. A brick flue was used at the corners, but it is likely that corner-pipes could be had; but the advantages of a brick flue at the corners enable the flue to be swept when necessary by merely removing the covering-tile. I leave others to calculate the respective cost of the two modes.

I have no doubt the boiler of Mr. Major is a good one, but I do not exactly understand its construction. I have seen a sort of a cylinder boiler standing alone without any connection with brickwork, excepting that an iron chimney from it led into a brick one on the wall. I believe this did its work pretty well; but as the boiler was in a back shed, it did as much towards heating that shed as it did in heating the glass house it was intended to do. I find, however, I must reserve my further notices on heating until another opportunity.—J. ROBSON.

GREENHOUSE GARDENING IN A SMOKY ATMOSPHERE.

A Subscriber will feel much obliged for the names of any plants whereby she may insure good flowers throughout the winter in a lean-to greenhouse, S.W. aspect, 27 feet long and 10 feet wide, heated by a flue. There are six good Vines in it, which are considered secondary to flowers. No man or boy is kept, but a man from a nursery helps occasionally. The lady is her own gardener, and has derived all her knowledge, which is very limited as yet, from that valuable work THE COTTAGE GARDENER, the rules in which she follows strictly, but the flowers are small and poor compared to those she desires to have. There is no power of placing the plants out of doors, although surrounded by a large garden of grass and evergreens, for copper, patent fuel, and brick smokes constantly prevail. She has good composts for the plants, and uses guano and water with great care twice a-week. The plants already in the greenhouse are—Geraniums, Fuchsias, Cacti, Crassulas, Acacias, Heaths, Azaleas, Roses (Moss), Calceolarias, Cinerarias, Heliotrope (large tree). Passion-Flower covers one side.

[It is against you not being able to put some of your plants out in summer. We would recommend six of the hardiest Camellias, including the double white; six Epacris, of various colours; two Coronilla glauca; two Cytisus racemosus; and two Cytisus Atkinsonii, a dwarf yellow; Cinerarias from seeds sown now, or slips or divisions in a week or two; four Salvia fulgens, well stopped until the end of August, and with plenty of pot-room; and the same of Salvia gesneriflora, not so much stopped; and two or three plants of Fuchsia serratifolia; and the same of Daphne indica and indica rubra, with Hyacinths, Tulips, Narcissus, Crocuses, &c., potted as early as you can get them, and these might be forwarded by being kept in a warm cupboard in the kitchen until well rooted.]

End View.

Ground Plan.

SUMMER-HOUSE.

THE summer-house here shown is from a design furnished by Mr. J. W. Chapman, of Richmond, Surrey, and is now being erected at "Heathlands," an estate of Amos J. Gann, Esq., Wokingham, Berks. It is placed at a point where a straight walk in the pleasure-ground terminates. Passing through the summer-house a curved walk commences, which is conducted round the whole park. There are some plantations of choice evergreens, &c., near the summer-house, which make a foreground to the views which are obtained from this point in three different directions. The summer-house is intended to be built of larch wood stained; and the tiles for the roof will be the small flat kind, of a dark brown-red colour.

MERITS OF ORCHARD-HOUSES.

I HAVE read with surprise the controversy which has been lately going on in THE JOURNAL OF HORTICULTURE respecting the merits of orchard-houses because, from my experience, I cannot understand how there can be two opinions on the subject.

In the year 1858 I built a lean-to orchard-house 17 yards by 4, and filled it with Peach, Nectarine, Apricot, and Plum trees, supplied by Messrs. Lane. This house answered so well that the next year I added to it another house 20 yards by 4. This second house was so entirely satisfactory that last year I increased its length by 12 yards. Some of my trees are in boxes, some in large pots, and others are planted in the open border. All seem to flourish equally well, bearing every year large and

excellent crops, with the single exception of the Apricots. One year I had an immense crop of Apricots, but generally they are few and far between.

In the year 1856 Messrs. Lane sent me twenty-five pyramid and bush Plum trees for planting in the open air. I gave them the best situation I could select, and certainly they have had all the attention they had the right to expect; but from the day they were planted up to the present time I have not gathered three dozen Plums from the whole lot. Three years ago I moved one of these Plum trees (a Jefferson) into the orchard-house, planting it in the border, and at once it took to bearing abundantly.

Some years back I laid out a considerable sum of money on

brick walls, and no doubt these walls answer well for Pears; but if I had my work to do again, the money which I spent on brick and mortar would be laid out on glass.

I have asked my gardener to put down on paper how he manages the orchard-houses, and I enclose his statement. At the present time all my orchard-house trees are loaded with fruit—Apricots only excepted. In my judgment the only way to secure a crop of Apricots in these northern parts is to have a heated wall, and this I believe to be a certain way.

I have hot-water pipes in the orchard-houses, but these are only used to guard against frost, and sometimes to ripen the wood in the autumn.—W. H., *North Lancashire*.

[The writer of the foregoing is a clergyman of high character, and the notes of his gardener are the following:—

"The trees are repotted immediately after the fruit is gathered, when all the soil is taken from the top of the pots and from the sides as deep as can well be got. The pots are then filled in with two-thirds of good soil and one-third of rotten manure, which is generally taken from an old Mushroom-bed. The soil is well beaten into the pots, and one good watering is given. Nothing more is required during winter, unless the wood seems to shrivel, when a little water is given. In the spring the trees are dressed with sulphur, soft soap, and clay, and the syringe is used twice a-day a short time before the buds begin to break. The syringe is not used during blooming. Just before the trees bloom the house is fumigated with tobacco-paper (and if it is fumigated twice, all the better), in order to keep the aphid away. Watering is a most important matter at the time of blooming. Water should be given rather sparingly; for if the soil becomes saturated with wet, the buds are sure to fall. The roots are confined to the pots; and after the fruit is set one heavy top-dressing of good rotten manure is given. If the green fly appears, the house must be fumigated without the loss of a day."]

MUSA CAVENDISHII.

THERE are certainly few more really noble occupants of the stove than a good plant of the *Musa Cavendishii*. There are others of the genus of much larger growth; but taking fruit-bearing qualities and other points into consideration, this is evidently the best for general purposes, and it produces as large an amount of fruit as any plant I know of that occupies the same space.

A bunch of fruit ripened here during the past winter which weighed on the whole 27 lbs. 8 ozs. avoirdupois, and consisted of 136 fruits, which, with the exception of one or two, were fully ripened and perfect. The barren end of the spike was cut off long before the fruit attained maturity, and, consequently, was not included in the weight named above.

The plant grew in a small corner of the plant-stove, which is much too low for it, all its leaves being broken at half their length. At the time the fruit was ripe the plant was about eighteen months old, it being a sucker from a plant that ripened fruit in the summer of 1861. In fact, the predecessor of the plant has occupied the same place with very little renovation of the soil for several years.

Perhaps some of your readers will record the weight and number of fruits that have been ripened elsewhere, as the above may have been exceeded.

I may add that, although the fruit ripened in February and early part of March, the flavour was good, and those who admire it consider it as good as any ripened in summer. This certainly is not the case with other fruits, and, of course, forms a recommendation of some consequence to this.—J. ROBSON, *Linton Park*.

TETRATHECA ERICÆFOLIA.

(HEATH-LEAVED TETRATHECA.)

Nat. ord., Tremandraceæ. *Linn.*, Octandria Monogynia. In 1805, Mr. Rudge published in the "Linnæan Transactions" a description, with drawings, of seven New Holland plants, among them is *Tetratheca ericæfolia*. Before that description was published in 1807, Sir J. E. Smith had described and portrayed the same species in his "Exotic Botany," t. 20. The specimens in both instances had been brought from the neighbourhood of Port Jackson.

Living plants of this greenhouse shrub were originally introduced in 1820, but long since lost, and it was reintroduced by

the agency of Mr. Drummond, in 1852. It is an evergreen subshrub, with erect branches, bearing linear heath-like leaves, which, on the more perfectly developed portions of the plant grow five or six in a whorl, but are sometimes scattered; they are revolute, with scabrous margins. From the axils of the leaves towards the end of the branches the nodding flowers are produced, so as

to form leafy spikes of blossom; they consist of a calyx of four ovate acutish sepals, and a corolla of an equal number of oblong, obtuse, pinkish-lilac petals; the anthers are dark-coloured, tipped with yellow, and open by a tubular orifice at the apex. The flowers have a very agreeable scent, resembling that of *Cyclamen persicum*; and, altogether, this is a greenhouse shrub deserving of extensive culture.

SOWING SOME PERENNIAL-FLOWERS' SEEDS.

A CORRESPONDENT asks us to state when the seeds of the plants named below should be sown, in order to have strong plants for bedding-out next summer—viz., *Heliotropes*, *Tropæolum*, *Gazania*, *Lobelia*, *Petunia*, *Cerastium tomentosum*, *Phlox*, *Cuphea*, *Gnaphalium*, *Mentha variegata*, *Perilla*, *Stachys lanata*, *Arctotis grandiflora*, and *Centaurea argentea*.

Commencing with the first of them, we may say, Sow the *Heliotrope* at once; and when cuttings can be had from the plants, propagate from the seedlings, as cutting plants flower better than seedlings. Sow *Gazania*, *Lobelia*, *Petunia*, *Cerastium*, *Phlox Drummondii*, and *Cuphea*, in a hotbed as early in the spring as you can—say by the middle of February, and encourage their growth by pricking out the young plants early into pans, and subsequently into separate pots if you have room for them. The *Tropæolum* and *Perilla* need not be sown so early—say by the end of May, as they grow quicker; and if you could winter an old plant of *Gnaphalium lanatum* you might obtain any number of cuttings in the spring, and they grow fast enough. A few old plants of *Mint* are also better than seeds, as the latter

may perhaps come up plain green. *Arctotis grandiflora* may be sown at the same time as *Gazania*, to which it bears some resemblance. The *Centaurea argentea*, or *C. candidissima*, might be sown at once, as the plants by being kept in pots do not grow fast; and, if they do so, cuttings from them will be useful. If you have not the convenience of a hotbed in which to forward the above plants next spring, but have a cool greenhouse or some pit where they can be secured from frost, it would be better to take cuttings of all of the kinds in August, and keep them in store-pots until March or April, when they may be potted-off, and will make good plants before planting-out time.—J. R.

GROWING MUSHROOMS IN POTS.

My experience in this mode of culture is by no means extensive, having only tried the system once, and that several years since. It proved perfectly successful; and some of your readers may feel inclined to ask this question—viz., Why not continue to practise it? My answer is simply the same as with regard to fruit. They can be obtained equally good, and with less trouble grown in beds in the usual way.

But for the benefit of any of your readers who may feel interested in the subject, I will detail my practice as correctly as I can. Early in the month of November, some years since, I found that it was desirable that I should produce Mushrooms as soon as possible. I had an excellent Mushroom-house under my care, but I had not a sufficiency of the material to make a bed—viz., horse-droppings. I, however, made a slight hotbed in the Mushroom-house, composed of half-rotten leaves, sweepings of lawns, &c.; and at the same time I carefully collected what droppings I could, so that by the time that the temperature of the hotbed had declined to about 80°, I had enough of droppings to fill three or four dozen nine-inch pots to within an inch of the top. These pots I at once plunged nearly to the rim in the hotbed; and when I found that the material inside the pots maintained a temperature of about 75° or 80, I inserted a piece of spawn as large as a hen's egg in the centre of each pot, making all very firm, and covering the surface of the pots with about an inch of stiff soil made quite damp. No water was ever given. In about three weeks the temperature of the hotbed had somewhat declined; the pots were then removed, a little fermenting material added to the bed, turning it at the same time, and immediately replunging the pots.

The temperature of the bed was never allowed to fall lower than 75°; and in rather less than six weeks from the day the pots were spawned, the surface of every pot was covered with small Mushrooms, which rapidly increased in size. As the atmospheric temperature of the house was kept to about 60°, on account of Sea-kale, Rhubarb, &c., being also forced there at the same time, this temperature brought the Mushrooms on faster than they were required. So they (the pots), were removed into a cool, dark, root-cellar, where they continued to produce excellent Mushrooms for some considerable time; in fact until a subsequently-formed bed could keep up the necessary supply—G.

HEATING GARDEN STRUCTURES.

THERE are few subjects of greater importance to the gardener than the proper erection of those edifices known as stoves and greenhouses.

Site or aspect is the first consideration. A site overshadowed by trees is unsuitable for fruits, though it may do very well for plants that delight in shade; yet even open sites are not always the best for the erection of houses for the successful cultivation of fruits. A site may be open but still bleak, and that materially affects the heating of the house and the giving of air. A sheltered situation is an essential in a climate like ours, and has more to do with the economical heating of houses than is generally imagined.

Suppose a house to be erected in a bleak place without shelter of any kind, and another to be put up in a sheltered situation. They are both heated alike, but the fire of one has to be kept going on a cold windy but sunny day, whilst that in the sheltered situation is warm enough without the application of fire heat. The one has the cold air driven against its sides, cooling the internal atmosphere faster than the sun's rays can heat it; but from the other, sheltered from the wind, little heat is abstracted by the air.

Yet a house may be cold irrespective of site. A house in a sheltered place with the laps of the glass open will be as cold as a house in a bleak situation with the laps putted-up. Then a lean-to house requires less heating than a span-roofed one. There is a loss in the latter of nearly one half of the sun's rays by reflection by the construction of the roof alone, to say nothing of its presenting a larger amount of surface to the cooling action of the surrounding atmosphere. A lean-to at an angle of 45° loses little from reflection in summer, but in winter nearly half the sun's rays are reflected: consequently a lean-to covering 300 square feet enclosing 2400 cubic feet of air requiring the temperature to be kept at 60°, will require 80 feet of four-inch hot-water pipe at a temperature of 212°; but a span-roofed house enclosing the same amount of air will require 60 feet more to obtain the same result.

I am not speaking of lean-to's and spans in their relative situations as regards light; I do not wish to maintain that lean-to houses are more suited to vegetation than a span-roofed, but to show that a quantity of enclosed air is more rapidly heated and more economically in the former than in the latter.

The size of the house also has a good deal to do with the heating. A small house proportionately requires more heated surface to heat it than a larger. The former presents a correspondingly greater amount of radiating surface to the surrounding air than the latter, and, as is well known, becomes sooner cold. A house 50 feet long by 20 will require 280 feet of four-inch pipe to maintain a temperature of 60°, and a house of the same length, but only 12 feet wide, will require the same amount of piping. The space in the latter will certainly be heated sooner to a given temperature than the larger house; but it will lose more by radiation and be cooled, in the same manner as it became warm, more quickly than the large house.

The heating of houses is also affected by moisture. Very moist atmospheres require a larger amount of heated surface to secure the same temperature in them than those several degrees drier. Our ferneries and Orchid-houses afford examples of this. I have noticed that a house in which a hygrometer denoted 95° of moisture (Saturation = 100) took nearly half a-day (5h. 45m.) longer to secure a temperature of 85° than a house with the same amount of heating surface where a hygrometer indicated 67° of moisture; and in cooling down the moist atmosphere was 4h. 57m. longer than the dry atmosphere.

Another point of no small import in the heating of houses is ventilation. It is necessary to provide for the admission of fresh air and the egress of foul. Stagnant air is inimical to healthy development in vegetation, and as the admission of fresh air is calculated to lower the internal temperature, provision must be made to prevent its doing so. The presence of the sun is the old-fashioned signal to give air; but as the sky is liable to be overcast for weeks, the atmosphere of our houses must be stagnant enough if no air be given during the sun's absence. It is not false economy to provide for a change of atmosphere at least once in twenty-four hours under all circumstances of cold and wet; and it is also necessary to provide for a fluctuation of temperature, or a rise of 10° or more above the calculated amount of temperature the heating apparatus is expected to secure.

Ventilation when it lowers the temperature denotes a badly-constructed heating apparatus. Many gardeners are prevented giving air through the deficiency in the apparatus, which may be theoretically properly constructed, and calculated to serve the purpose for which it was intended; but from the builder's ignorance of the smaller matters we have pointed out he makes a sorry affair of an otherwise good one, and often throws the plants into diseases which are attributed to the gardener. A few additional feet of heating surface is a good excess; in fact, a necessary help to successfully grappling with the vicissitudes of a fickle climate. There are only three ways of heating houses: by fermentation, hot water, and hot air. The first is spontaneous, therefore more suited to vegetation than any other heat (solar heat excepted). It is easy of application, and satisfactory in its effects; but its utility is materially impaired by the frequency of the necessity to renew it and the constant care necessary to secure the proper heat. Formerly dung was pre-eminently the best material for hot-beds, and it is now the best—at least, the most conducive to vigorous growth—for forwarding and maturing the fruits of plants of short duration. It has also the advantage of maintaining a steady bottom heat; but it cannot be made to raise the internal temperature 10°, without solar heat, in a few hours, on the occurrence of a very frosty night, neither is it easy to

cover up a large forcing-house with protecting materials to prevent the inmates from being chilled. The trouble in renewing, and the limited supply of dung at command, have done much to cause cultivators to look out for something more lasting, and as near resembling a natural system of heating as possible. Still all our aged practitioners insist on there being nothing like a bed of fermenting materials to give plants a start, by promoting root-action before leaf-development commences.

Dr. Haley, of Edinburgh, published a treatise on heating hotbeds by the steam of hot water about 1750, which was translated into French and again translated into English, appearing in the "London Magazine" for 1755 as a new plan for heating hotbeds, with a foreign signature attached to it. The system consisted of a boiler to generate steam, and stone pipes with uncemented joints heated the bed. It would appear from this that the chief aim of cultivators of that date was their desire to produce an apparatus that would give the results of a hotbed in perpetuity without any of the trouble and inconveniences of a bed heated by fermenting materials. Steam, however, was a very unmanageable agent, and though some people did very well with it, yet others barely got their plants into a fair way, and were just beginning to understand the system, when by some oversight a valve became choked, and the plants that were in a flourishing state the night before were found scalded; the boiler was rent into fragments, and the anticipations of the operator frustrated.

Flues, the medium through which hot air is conveyed, are of remote antiquity, and were introduced into this country for garden structures at the period when Dutch gardens were in vogue. Flues were first used to keep the frost out of the greenhouses of that date, and to prevent the frost destroying such plants as *Kerria japonica*, *Pæony Moutan*, and *Aucuba japonica*. They were constructed similarly to what they are now, and although that mode of heating was applied to the cultivation of plants requiring a high temperature, yet the flue remained in its almost original condition, or unimproved. At no period were gardeners very partial to this mode of heating, for we find them heating their hotbeds for Pines, and growing them by dung heat satisfactorily without a flue at all. Vines, too, were brought forward by a bed of fermenting materials, the flue being only used as an auxiliary to ripen off the fruit. Dung, tanner's bark, &c., were more or less used to promote warmth in the first stages of early forcing, for very obvious reasons—the heat was moister than that of a flue, became more equally diffused through the house, and was not liable to burn the plants at one end and starve those at the other. Besides, flues are liable to dry the air too much, and so, instead of conducing to healthy development, may prove baneful by drying up the juices of the plants, and unsatisfactory in their results.

Heating by hot water was not much in vogue until it became known through Loudon's "Gardeners' Magazine." Its cost was a hindrance to its general application; but still it gained ground, and is now generally adopted.

On these two latter modes of heating garden structures I propose to offer a few remarks. I shall not attempt to disguise my prepossession in favour of hot water, nor will I say one word more about either than has been confirmed by experience.—G. A.
(To be continued.)

GRAPES AND OTHER GARDEN PRODUCE IN AUSTRALIA.

FROM correspondence received by the last mail, we find that the cultivation of the Vine is likely to become a most important branch of industry in the Australian colonies. The area adapted for the growth of this plant is practically unlimited, and we believe no pursuit can be entered upon that promises more certain remuneration to an industrious and enterprising person possessed of a little capital. The slopes of the ranges seem almost as if designed especially by nature for the Grape, and it is not surprising that the experiments that have been tried have proved remarkably successful. Several parties in the colony of Victoria have fenced in from 50 to 100 acres for the cultivation of the Grape, and we know of parties having 80 acres in full bearing. Wine-presses are being erected capable of pressing 10 to 15 cwt. of fruit at one time. There is one vineyard alone, the produce of which will amount to upwards of 200 hogsheads this season, the entire crop of which has been sold to one wine-merchant. The price of the colonial wine is 16s. per dozen. The

sorts usually cultivated are Black Hamburgh, Black Prince, Muscat of Alexandria, Black St. Peter's, &c. The bunches usually grow very large, some have weighed as much as 10 to 11 lbs. each. The individual berries attain considerable dimensions, many being nearly as large as black Plums. With such facts before us we can more readily credit the tales of eastern travellers about the monstrous products of the Syrian vineyards. The mode of cultivation is very different from that pursued in England; the Vines are planted about 5 feet apart, and trained in a similar way to espalier Apple trees. There are upwards of 4000 acres employed in growing Grapes in this colony.

Tobacco also is being largely cultivated and with tolerable success, but a great drawback is that the rainy season interferes with the drying it, so that they are obliged to resort to artificial means, which injures the quality.

Some of the Chinese diggers have just commenced to grow ginger, and it is said by the growers to be in quantity and quality equal to that grown in China, which is the native habitat of the root.—W. P., JUN., *Camborne*.

WORK FOR THE WEEK.

KITCHEN GARDEN.

CONTINUE to thin the crops that require it whilst they are small, and in every case where practicable loosen the soil about them. If dry give them a good watering, when the soil being loose its beneficial effects will be so much the greater. *Basil* and also *Marjoram* that have been sown in beds to be thinned out to about 6 inches plant from plant. *Beans*, make another sowing. Top the most forward, if not yet done. *Beet*, make a small sowing of Red. When it is sown early in rich soil, it sometimes becomes too large and coarse, and does not retain its colour in boiling, nor looks so well in salad, as that which is smaller of the same variety. *Carrots*, make a small sowing of Early Horn. *Cabbage*, sow a little seed for autumn produce. Some of the smaller sorts should be preferred for this sowing. *Cauliflowers*, plant out some from the first sowing in the open ground. A small quantity planted from two or three sowings will keep up a succession better than the small stunted plants of very early sowings. *Cucumbers*, peg down the plants on the ridges as they advance in growth, and when the hand-glasses will no longer contain them, set these on three bricks placed edge-ways or on croch sticks. When they require water give it to them milkwarm early in the day. *Onions*, after thinning loosen the soil between the rows, and if the weather is dry give them a thorough watering. The thinnings of the beds to be planted out and to be watered every night if the weather is dry until they take fresh roothold. This must be particularly attended to, as the roots should be very near the surface. *Peas*, the last sowing of Knight's Dwarf to be made, as it is longer in coming into bearing than any other. Continue to earth-up and stick the advancing crops. If the pods of the early crop do not fill well in consequence of drought, give them one good root-soaking which will be sufficient for them while they last. The method frequently pursued of giving plants in the open ground a "small drop" of water every evening or morning cannot be too much deprecated, such sprinklings cake the ground and lower the temperature of the soil without any corresponding benefit to the plants. *Radishes*, make another sowing of the various sorts. *Savoy*s, plant out some of the early sowing. The dwarf sorts may be planted at 1½ foot apart in the rows, the rows to be 2 feet from each other. The larger sorts to be 2 feet from each other in the rows, and the rows 2½ feet apart. *Tomatoes*, as they are usually planted under a south wall where they receive but little benefit from a passing shower, they should be occasionally watered and kept mulched with short litter. Nail and stop the shoots as they advance in growth. Hoe, rake, sweep, and keep every part of the garden clean.

FLOWER GARDEN.

Pay particular attention to the stirring of the soil amongst the plants in beds and borders. This will be attended with the best results; let it be continued until the plants begin to grow and cover the surface of the bed, when it should be discontinued. Be sure that plants growing in vases, baskets, &c., are properly attended to, and thoroughly watered at the close of these hot days. A full sowing to be made of Brompton Stocks and all biennials for the flower garden. Make a successional sowing of some of the choicest hardy annuals for autumn-flowering. Hollyhocks to be

staked and tied, and attended to as they advance in growth. The Roses should likewise have all the attention that can be spared at this busy season. Remove all superfluous shoots and suckers, and keep a sharp look-out after insects. One great fault to be frequently met with is, mixed beds or borders of herbaceous plants with stiff high plants at the edges. Where sufficient variety does not exist, some of our dwarf plants, such as Mignonne, Musk, Forget-me-not, Verbenas, and Calceolarias may be introduced with advantage. The newly-planted things will require frequent attention, as under the best management failures will sometimes occur. These should instantly be made good, and the tying and staking of everything requiring support on no account delayed. Where an immediate display of flowers is not wanted, the buds may be pinched off for a week or two to encourage the plants to cover the ground. Creepers against walls and trellises to be constantly gone over to tie or nail them in. Take early means to eradicate all the broad-leaved plants and coarse-growing grasses from the lawns which they much disfigure, and keep them closely cut with the scythe or mowing machine.

FRUIT GARDEN.

Attend to disbudding Peaches, Nectarines, Apricots, &c. Pick grubs off Plums, Apricots, and Pears. Syringe Cherries, &c., to destroy the aphids. Give Strawberries a thorough soaking after the blossoming period, and put some wheat straw or other covering between the rows to prevent heavy rains from soiling the fruit. Thin the shoots of Raspberries to two or three of the strongest if not already done. Disbud Figs, retaining no more wood than is required for the next season.

STOVE.

Let rambling shoots have frequent stopping. Shift Gloriosas, Erythras, Clerodendrons, &c., and give liberal supplies of weak manure water. Continue to shift all Orchids that require it. The best time for shifting Saccalabiums, Vandas, Camarotis, Ærides, and all similar plants is as soon as they have done blooming. Now is a good time to pot Peristerias, Phaius, and Cymbidiums that are starting into growth.

GREENHOUSE AND CONSERVATORY.

Young growing plants of Heaths and other hardwooded plants to be placed in a spare pit where the lights can be readily removed, to take advantage of dews or light showers; and where the shading, which will sometimes be necessary, can be readily removed, plunge the pots about half their depth in cinder ashes. The stock of Balsams and other annuals grown for filling the vacant places in the conservatory, &c., should be encouraged by frequent shifts. Keep them in bottom heat and near the glass. Pick-off the early-formed bloom-buds, as the plants should attain a considerable size before being allowed to bloom. Continue to train Kalosanthes, and water with liquid manure occasionally. Scarlet Geraniums to have liberal encouragement to grow them on. Fancy Pelargoniums for late-blooming will thrive better in a somewhat shady situation, and where they can at the same time be protected from heavy rains. Fuchsias, if not in their blooming-pots, should be transferred to them forthwith. Train in the desired form, and pinch back weak and straggling shoots.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

EARTHED-UP Cauliflower to keep it moist, as the weather with us continues very dry, and we are afraid of quite running out of water. Did the same with Peas and Beans for a similar purpose. Shaded young Turnips, &c., for the same purpose, and hoed with a Dutch hoe among growing crops, weeds or no weeds, in order to give a loose surface, which arrests evaporation almost as effectually as covering with a mat or litter. One disadvantage is that the loose surface keeps out heat as well as keeps in moisture. Grubbed out and wheeled to rubbish-heap, to be covered with soil, the greater portion of the Broccoli; had the ground well trenched-up, and a little dung added, and will sow with Peas, watering them well, and will stake this the last sowing of the Marrowfat kinds. When we read such directions, "Trench-up spare ground for early crops of Greens, Broccoli," &c., it is enough to make one's teeth water with envy, and especially when we happen to see large quarters lying fallow for half the summer. No doubt it is more pleasant to be able to do things in this regular fashion, and to take only one or two

crops from the soil in one season; but there are many of us who can hardly ever give the ground a moment's rest. For cropping in this style it is a great advantage to be able to get hold of a border in which lots of the Brassica tribe may be pricked-out in rich soil, and 3 or 4 inches apart, and then they may be transferred with the trowel to places as soon as room can be found for them. At present we have not a piece vacant; but one planted with early Potatoes, which we purchased to get a change of seed for next year, but the ground being so dry, though all right below, the tops of the Potatoes have not appeared above-ground as yet. We may also say the same as to Asparagus and Sea-kale seeds that were sown; for, though all right, there has not been enough of moisture to tempt the seed-leaves above the ground, and such things we cannot think of watering. Regulated Cucumbers, Dwarf Kidney Beans in bearing, and stopped and watered those merely under glass protection; also placed ridge Cucumbers, Vegetable Marrows, &c., under a cold frame to harden-off the plants for open air, but will, if possible, give a few the protection of some old lights over them, as those on ridges have not done first-rate for several years. Thinned Lettuces, and planted a lot on the north side of a bank, where we think they come sweetest and best in summer; but had we plenty of ground we would not transplant at all, but would sow thinly in rows, and thin to a foot or more apart. We always think there is an additional crispness in sown Lettuces over transplanted ones, and then the labour is less. Pricked-out Celery, and will plant-out some of the earliest as soon as the trenches are cleared of bedding plants. Cut the flowering-stems of most of the Sea-kale; this in the young state makes a nice vegetable when boiled, and would be preferred by many to a succulent Cabbage, though that, too, is very nice.

General treatment much the same as before.

FRUIT GARDEN.

Caterpillars appeared on some Gooseberry-bushes; but when we thought of starting them with a sprinkling of soot we found there were none to sprinkle, and hope they will not return again. Of course the birds will get the credit of this, and I suppose they deserve it, but we were too busy elsewhere to be quite sure of the matter from observation. Gooseberries will be a very heavy crop, although the frost nipped a few, and did some injury to Currants. Went over Cherry trees, regulating the shoots, and steeping the points infested with fly in weak Gishurst, and engined strongly with clear soot and lime water several times afterwards, and watered at the roots in some cases as previously detailed.

Thinned fruit in orchard-houses, which in some cases had set as thick as ropes of onions. Will use the fruit bruised-up for prussic acid tea, as but few will be used for tarts. Thinned Grapes, regulated shoots in late vinery, and attended to Melons, setting the fruit on slates and bricks, and keeping those in bloom rather dry. Out of doors we hope we shall get a good drenching for the Strawberries, as we should like the ground well wetted before putting straw or litter between the rows. In syringing and engining at this season we can hardly fail to hear lots of encomiums on two kinds of *hydropults*.

We have not a word to say against them, and the immense sale renders them independent of anything of that sort. Never, however, did we know a case more illustrative of what "there is in a name." Ladies are quite enraptured with them. We have had specimens sent to us, with and without pails, and can see no advantage in them, except the flexible tube, which, in many cases, would be an advantage, and the flexible suction-tube which might be placed in a cistern in a house, and the hydropult worked at the farther extremity. Hearing so much of the ease in working the "pult," we were quite surprised at the muscular exertion required in the several specimens sent to tempt us into the purchasing vein. No doubt there will be the advantage of not getting out of order easily; but as a deliverer of water with force, and to a good distance, the want of an air-vessel and good lever power, to lessen the necessary exertion, will, in our opinion, be drawbacks to the continued popularity of the hydropult.

As this is the time for looking over Pine plants, some inquiries have reached us as to mixing old and new tan together for Pine-beds, Melon-beds, &c. When we used tan rather largely, we gave up mixing it, as the heat was thus made so irregular, and often so violent. We preferred placing the new by itself at the bottom of the bed, and the old at the top, or just the reverse, if the tan though new was sweet, so as not to injure anything. For

Melons, if we suppose there were 18 inches of tan rather old, and 18 inches of fresh, we would mix the new and old together for 27 inches, and have 9 inches of the older between the mixture and the soil. That thickness would keep a regular heat a long time. Attended to watering Figs, Peaches, &c. Potted Vines, placed the plants where they could have more light, and gave routine treatment as detailed in previous weeks.

FLOWER GARDEN.

Here daisy-kniving, rolling, mowing, and planting, have been the order of the day. Would have done more of the latter if the weather had not been so dry. Hoed among the bed planted to keep the surface rough and open. As already noticed, we have done the main ribbon-borders in straight lines this season, and think they will look well. There is one sloping border against a south wall between 300 and 400 feet in length. This border is 12 feet wide, and at the back is raised 2 feet above the pathway in front, sloping down to the verge. On the other side of the walk is a double-sided border rising also in the middle, 14 feet wide, and having slight iron columns 18 feet apart along its centre and 7 feet above the walk for chains to be suspended between each for creepers. On the wall border, which wall is covered with Roses, creepers, &c., the first line of ribbon is 4 feet from the wall, from thence to the verge are seven rows more, making eight in all. From the slope of the ground there is room enough for these to be massive in the rows, and they make more room for themselves as they grow. The object is to have every line distinct, and yet no space left between the rows, but the one to abut on the other. The rows are as follows, beginning next the wall—*Salvia fulgens*, 18 inches apart; *Ageratum*, 16 inches apart, strong bushy plants; *Trentham Rose Geranium*, 13 inches apart; double white *Feverfew*—fine strong plants—9 inches apart, but every other plant is nipped down to secure continuance of bloom; *Perilla*, not yet in, 1 foot or so apart; yellow *Calceolaria*, strong, 1 foot; *Brilliant Geranium*, 1 foot, strong plants; and next the verge *Cineraria maritima*, 1 foot apart, being the first time we have had it in a straight line.

The border on the other side is shorter, but is planted in the same manner, the line on the top of the ridge being *Salvia*, and then the seven others on each side.—R. F.

TO CORRESPONDENTS.

SOFTENING HARD WATER FOR PLANTS (A Subscriber, Devizes).—As you are compelled to use such, though a tank supplied from the house and greenhouse roofs can usually prevent such compulsion, we recommend you to have the pump water mixed with a little soda, such as washerwomen use—one pound to sixty gallons—and let it after the mixture be exposed to the sun and air for a day before using.

VINE-SHOOTS GANGRENED (T. J. S.).—We think the cause of the ends of the Vine's young shoots "fogg-off," or gangrening, as in the specimen sent is, that the roots have descended into a cold or ungenial soil. We would remove the soil down to the first tier of roots, and replace it with a mixture of equal parts light loam and decayed stable manure. If the roots are outside the house, cover the surface with mulch at night and during cold days, but have it uncovered during sunny days and warm rains.

SMELL FROM LIQUID MANURE (N. D.).—There is no offensive smell from any liquid manure except house sewage. The smell from this may be removed by mixing with it a little chloride of lime, but the earth itself is the most effective deodoriser. The smell of the most offensive liquid manure is gone in an hour after it has been poured upon the soil.

BOILER AND PIPING FOR A PIT (T. Record).—A small tubular boiler such as used to be made by Stephenson would suit your purpose, and so would a small saddle-back boiler. If you merely wanted Cucumbers and Melons in summer two three-inch pipes all round your span-roofed pit, 50 feet by 12 feet, would suit you, though, notwithstanding the extra expense, we would prefer four-inch pipes. We are supposing that you do not mean to give the Melons much bottom heat, though in such a long house a part might be shut off to have Cucumbers early; but then you would require pipes for bottom heat.

MYRTLES NOT FLOWERING (C. H. R.).—Like most things, Myrtles flower best when they have been exposed to the full sun, which gardeners are unwilling at times to allow these potted plants, as it browns the foliage. We have it flowering most seasons against a wall outside, and producing myriads of berries; and if your plants were well ripened the preceding season you would have flowers also, although, as stated above, the foliage might not be of so delicate a green.

GERANIUM REIDII (Idem).—We cannot affirm that the leaves you have sent are from *Geranium Reidii*, as we know but little of that variety, and it is difficult to name anything from leaves only, and bedding Geraniums, which are now so numerous, cannot well be named without seeing a full-sized plant. It is very likely your gardener is right, as it is a red-zoned variety somewhat in the way of *Blazer*.

BLIGHTED LEAVES ON PEAR TREE (An Old Subscriber).—These appear to be caused by the cold winds we have had of late, at a time when the young foliage was in a delicate condition. The return of drier weather is the best remedy, if not the only one; but if the foliage that is to come becomes in like manner blistered and diseased, then something else is the matter, and we will be glad to hear from you again.

WATER-CRESS CULTURE (Agricola).—The following system, which is that followed in the metropolitan counties, for the supply of the London market, we extract from "The Cottage Gardeners' Dictionary." The green slime of which you complain arises from the water being too stagnant. Let all the water off from each terrace occasionally, and keep a gentle flow constantly:—"The trenches in which they are grown are so prepared, that, as nearly as possible, a regular depth of 3 or 4 inches can be kept up. These trenches are 3 yards broad, and 87 yards long, and whenever one is to be planted the bottom is made quite firm and slightly sloping, so that the water which flows in at one end may run out at the other. If the bottom of the trench is not sufficiently moist, a small body of water is allowed to enter to soften it. The Cresses are then divided into small sets or cuttings, with roots attached to them; and these are placed at the distance of 3 or 4 inches from each other. At the end of five or six days a slight dressing of well-decomposed cowdung is spread over all the plants, and this is pressed down by means of a heavy board, to which a long handle is obliquely fixed. The water is then raised to the depth of 2 or 3 inches, and never higher. Each trench is thus planted annually, and furnishes twelve crops during the season. In the summer the Cresses are gathered every fifteen or twenty days, but less frequently during winter; care is taken that at each gathering at least a third part of the bed is left untouched, so that neither the roots may be exhausted, nor the succeeding gathering delayed. After every cutting, a little decayed cowdung, in the proportion of two large barrowfuls to each trench, is spread over the naked plants, and this is beaten down by means of the rammer above mentioned. After the Water-cresses have been thus treated for a twelvemonth, the manure forms a tolerably thick layer at the bottom of the trench, and tends to raise its level. To restore it to its original level, all the refuse should be thrown out upon the borders which separate the trenches from each other. These borders may be planted with Artichokes, Cabbages, or Cauliflowers."

CAMELLIA LEAVES PARTLY YELLOW (H. M. P.).—But for your statement we should have supposed that the larger leaf was going through its natural course of decay before dropping from the stem; for evergreens are to a certain extent deciduous, and part with their old leaves as well as deciduous trees, though not in winter as the latter do. From the details you give we are convinced that the plant is suffering from bright sun and condensed moisture or hot vapour. The remedies are shade in bright sun and air early in the morning, or rather on constantly, so that the leaves shall be dry, and no moist hot vapour about them when the sun reaches them.

COBEA SCANDENS FLOWERS ALTERED (Idem).—We have noticed the change into a five-segmented corolla of the flower of the *Cobea*, and the extra strength from standing the winter may be partly the reason. Though somewhat rampant, there are few more splendid climbers, and the large bell shows so many tints of colour.

LEAVES INJURED (L. N.).—We should attribute the holes in the Horse-chestnut leaves to insects or caterpillars. From what we could see of the Vine-leaves, which were much dried, they seemed to have been scorched, or rather scalded, by the sun shining on them when in a damp state. Air early in the morning or a little all night will remedy that. The Golden Hamburg would be better to be suspended 9 inches farther from the glass, or a little shading put on the glass.

ROSE-LEAVES (W. X. W.).—With spectacles on nose, and with a microscope to help, we failed to find one insect on your Rose-leaves. There were marks as if a scale had been on them, which must be washed off if there, and also marks as if thrips had been nibbling, and these must be smoked and syringed. We are not certain on either point as to these insects being present; but we must say that it is rarely an insect will come to us. If the leaf is merely put into a letter, it should be enclosed in a box or something, to prevent the insects getting away or being smashed by the post-office punches.

VINE-LEAVES BLOTCHED (B. A.).—The leaves were quite dried when we received them, and we have no doubt the blotches are produced by scalding—by the sun shining on the leaves when in a moist state, or from there being some scars or knots in the glass. In the latter case paint the scars over, or rub them with putty; in the former give air early, so as to have the foliage dried before the sun strikes powerfully on the house. The great vigour of the Vines would render them more liable to the casualty in either case.

BEDDING GERANIUMS FOR A COLD DISTRICT (B. H.).—We have no doubt but the kinds you mention—*Madame Vaucher*, *Princess of Prussia*, and *Christine*—will do as well as any other in such a situation. Generally speaking, the kinds most impatient of cold are the variegated kinds, especially the golden-edged varieties. In cold or late places old plants are better than young ones, and a tolerably good show will be had; but it is needless to say that in more favoured situations it will be better, although we are far from certain but that you will beat your more warmly located brethren in *Calceolarias* and *Verbenas*.

SOWING ZINNIAS, SWEET SOULTAN, AND ANEMONES (A Would-be Gardener).—It is almost too late, excepting under favourable circumstances, to sow the two first-named annuals; but if you have a hotbed, and can sow a quantity in separate pots, and thin them out when they come up, and gradually harden and plant out, they will succeed pretty well. *Anemone* seed may be sown when ripe. Cover very slightly, and do not water however dry the weather may be, and it is likely you will be successful.

DESTROYING DAISIES ON A LAWN (J. Searle).—We fear we cannot give you much hopes of entirely eradicating this inveterate pest. Taking up the turf and relaying it, or, what would be better, exchanging it for other turf less affected with daisies, and at the same altering in some measure the character of the ground by adding some enriching substance will partially remedy the evil; but the easier way is to cut off the heads of the daisies every alternate day with the "daisy-knife" described at page 378, which is by far the best tool we are acquainted with for the purpose. In the after part of the season you will be less troubled with these common-looking flowers, but most lawns are more or less troubled with daisies in early summer. Weeding is a tedious job and far from effectual, and ground favourable to the growth of daisies will produce them in spite of all ordinary preventives, that we advise the more frequent cutting of the heads as the best and cheapest manner of abating the evil.

FLUE-CLEANING.—The simple plan of heating a small greenhouse, described by "J. B.," is exactly suited to my requirements, and he would oblige by stating how the flue is to be cleaned, as I conclude it would not answer to break the mortar and remove one of the pipes.—A.

FERNS IN A PLANT-CASE (E. Payne).—You will see a work on the subject announced in our Journal to-day.

DWARF SWEET PEA.—I have often thought why a dwarf Sweet Pea has not been obtained as well as a dwarf eatable Pea. Can botanists or florists give a reason?—M. F.

DESTROYING THE BLACK FLY ON CHERRY SHOOT (An Old Subscriber).—If your trees be against a wall, it is good practice to bend the tips over and into a basin of tobacco water, so as to immerse all the part affected. A syringing of the tree will do some good, though not so much as dipping. Should this process appear too tedious, nipping off all the tips is the next best remedy. Cherries are generally infested with this insect.

REMOVING WHITE LILIES (A Would-be Gardener).—As soon after the flower-stem dies down as convenient, as at that time the bulbs are at rest. It is, however, better to plant them at once, and not lay them by for a season as is done with Hyacinths, Tulips, &c. They are not particular as to soil, and are often seen in cottage gardens in great perfection, where they have not been disturbed for years.

ROSE-LEAVES CURLING-UP (C. H. R.).—Cold winds will cause this at times when there is no insect, but generally the latter accompanies it. If it arise from the former cause there is no preventive for out-door plants; but insects may be destroyed by dipping each shoot in a decoction of tobacco, rubbing the leaves at the same time through the fingers. Taking the case in time is the best preventive. The evil is, however, a very common one, and generally is submitted to in large collections as being too tedious and expensive to overcome.

WATERING PLANTS (Old Subscriber, Hampshire).—No harm can be done by watering the roots of plants at any time of the day, but the foliage ought not to be wetted in the bright glare of sunshine. It would be a hopeless affair to leave all watering until the sun went down. In dry weather one or two men are watering here all day long. In the middle of the day potted plants that are needing it are supplied; and in the morning and afternoon (say after half-past four or later) those plants whose foliage must be wetted are supplied with water; but we are promised an article on this subject by one of our contributors.

MATCH BED TO CALCEOLARIA AMPLEXICAULIS (B. H.).—If the beds are near together, so that the eye will catch both at once, plant both with the Calceolaria; or if you have not sufficient plants, plant the centre of both with it, and the outside with Calceolaria Aurea floribunda, or some similar kind. The writer of this article is more in favour of symmetry than of multiplying varieties; and, assuming you to edge the bed with something else, the two kinds of Calceolaria will do very well for the centre.

VARIEGATED AGERATUM (Idem).—The white edge of this plant is not sufficiently clear to look well, but it flowers tolerably freely, the only difference being that it is dwarfer than the plain; but the variegation of the foliage is not white enough to entitle it to more than a second or perhaps third class place among plants of white or variegated foliage.

EDGE FOR A PERILLA-RED (Idem).—Seedling plants of Cineraria maritima, though for a time less white than cutting ones, are, nevertheless, preferable to variegated Balm; as likewise is variegated Alyssum, with its myriads of white flowers. A variegated Scrophularia also promises well; while the Centaurea candidissima is unquestionably the best white-foliaged plant we have for this and like purposes.

NAMES OF PLANTS (T. T.).—1, A Dacrydium, probably Mai; 2, Carmichaelia australis; 3, Dacrydium excelsum; 4, Ciantus puniceus; 5, Phyllocladus trichomanoides. (Philos, Pilkington).—6, Hippeastrum reticulatum, v. striatifolium. (Mrs. W.).—1, Alonsoa Warszewiczii; 2, A Gnaphalium, probably G. arenarium, but cannot be certain without knowing the plant's habit. (Subscriber).—1, Alchemilla vulgaris; 2, an umbellifer without leaves or fruits; 3, Veronica chamaedrys; 4, Lychnis diurna. (Eight-years Subscriber, Gravesend).—1, Hardenbergia menophylla; 2, Polygala Dalmatiana; 3, Abutilon venosum. Nos. repeated.—1, Asplenium filicoides; 2, Adiantum capillus-Veneris. (Tyro, Chesham).—Polypodium dryopteris. The book on exotic Ferns is in the press; you will soon see it announced and the price. (Juvenis).—1, Geranium Robertsonianum. The rest have no leaves. We cannot afford time to examine such specimens. Those who want this kind of information must take the pains at least to send decent specimens, and so packed as to come in good preservation.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

NORTH HANTS POULTRY SHOW.

The growth of poultry shows in connection with agriculture is slow. We must wait till we have such statistics as they have in France. Where, as in that country, a large sum is put down as the value of the poultry stock of the kingdom, attention will be drawn to the subject, and it will take the prominence it deserves. Few things are more profitable as food or more valuable; few things of as little money value and as inexpensive to keep will provide as much food. A hen that rears twenty-four chickens in the year has earned money, not only by this fact, but by the surplus eggs that are eaten or sold.

Poultry is kept on every farm, but it is not made a pursuit; nor is it studied. Every other description of live stock is turned to the best advantage. Times, seasons, and age are all studied with a view to the greatest productiveness and the best return for outlay. Not so the poultry. The chickens are killed off and eaten. The old stock remains year after year, becoming less prolific as they get older, and it is then declared poultry does not pay. We need hardly say with such feeling and such management there will not be pride enough in it to cause a desire to exhibit. Yet at every agricultural meeting the poultry is first visited—it forms the chief attraction; and many say they believe they have better birds at home than those that take

the prizes. To every other class the pursuit affords real pleasure. The clergyman, the physician, the solicitor, the merchant, and very often the statesman, make it one of their relaxations. Exhibitors grow from these classes because they watch their birds, and discover their merits, which the agriculturist, who has all the machinery for success at work, whether he will use it or not, cares for the Gallinaceæ only when chickens are wanted for the table or eggs are "desiderata" at the breakfast table.

We confess to a liking for an agricultural meeting. It is to the county what the Christmas gathering is to the family. It is a holiday in which all classes share. Though we do not go to the length they do in Ireland, as related in the *Times*, where the two-year-olds and the three-year-olds have handed down the feud that began about a cow from father to son till its sad records are written in the history of every assize, yet we are always amused at the delight evinced by those who come from the particular village or district that has produced the first-prize animal. There is a heartiness in the pursuit which is shared by all who are concerned in it, and there is an absence of selfishness which is a relief to many who have been for years subject to the close competition and comparative selfishness of those who have been their neighbours, and have followed the same calling as themselves in large towns. The man who has had charge of the horse, ox, sheep, or pig that has taken first honours has, perhaps, more real interest (apart from the money question) in the success than the owner. Hence it becomes a holiday for all.

The *Dorkings* were very good, and the exhibitors lay far apart—Somersetshire, Wiltshire, Buckinghamshire. Mr. Brown, of Chard, took first with very large birds; Mr. Fowler, of Aylesbury, second. All the pens were shown in excellent condition; but these two pens were remarkable in that particular. Among the *Cochins* there were, as usual, many faulty combs. The first prize went to Nottingham; Mr. Fowler took the second. It will speak for a good class of *Game* when we say that Mr. Rodbard could only win a high commendation. Mr. Sidney Dupe, of Bath, showed a remarkably good pen. He was hard run by Mr. Adams, of Basingstoke. Hampshire is strong in *Polands*, and the class did not belie the reputation of the county. Mrs. Pettat and Mr. T. P. Edwards left nothing to desire in their prize pens. With one exception, the *Spanish* were deplorably weak in quality. Mr. Rodbard sent a pen worthy of any exhibition in the kingdom. The second prize was withheld, as, in four others, the cocks had falling combs. There was strong competition in the *Hamburgs*—Mrs. Pettat took both prizes. It was hard to give only high commendations to Messrs. Brown, Keable, and Lamb—it was truly an excellent class. Mrs. David Smith showed one of the best pens of *Turkeys* we ever saw. Mr. Matthews was deservedly a prizetaker, and Mr. Boxall's were good birds. Where Mr. Fowler shows *Geese* he is generally successful. His pen weighed 55 lbs., and Mr. Mansfield's improved White Dorset weighed 48 lbs. The latter would have been a great weight some years since. There was a good entry of *Ducks*, and Mr. Fowler was again at the head with three birds weighing 21 lbs. Mr. Rodbard's Rouens were second. Mr. Fowler showed three ducklings that weighed 18½ lbs. Six pens of otherwise good Rouen Ducks were disqualified by the lead-coloured bills of the Ducks. There should be no mistake on this head. The Rouen Duck should in every particular but size be the counterpart of the wild Duck and Mallard, and no wild Duck was ever seen with a leaden bill. Among the extra stock were some exquisite Duckwinged Game Bantams belonging to Mrs. Pettat, and some very good Silkie shown by Mrs. St. John.

A lovely day, music, and a large attendance, especially of ladies, added to the liberal arrangements of the Show; and the untiring exertions of the Committee, with the tact, kindness, and urbanity of Mr. Downs, made this meeting a "very" holiday.

DORKINGS.—First, T. L. Brown, Chard. Second, J. K. Fowler, Aylesbury. Highly Commended, C. Smith, Salisbury; Mrs. D. Smith, Browning Hill House. Commended, W. B. Boxall, Strathfieldsaye.

COCHINS.—First, C. T. Bishop, Lenton. Second, J. K. Fowler, Aylesbury. Highly Commended, Rev. J. D. L. Simmonds, Chilcomb Rectory, Winchester; Mrs. St. John, Oakley Cottage.

GAME.—First, S. Dupe, Bath. Second, E. S. Adams, Basingstoke. Highly Commended, J. R. Rodbard, Wington, Bristol; S. Jesse, Basingstoke.

POLANDS.—First, Mrs. Pettat, Ashe Rectory. Second, T. P. Edwards, Lyndhurst. Commended, Mrs. Pettat.

SPANISH.—First, J. R. Rodbard, Wington, Bristol.

HAMBURGS.—First and Second, Mrs. Pettat, Ashe Rectory. Highly Commended, J. Keable, Thatcham, Newbury; J. Lamb, Highworth, Wilts; T. L. Brown.

TURKEYS.—First, Mrs. D. Smith, Browning Hill House. Second, H. Matthews, Sherborne St. John. Highly Commended, W. B. Boxall, Strathfieldsaye.

GESE.—First, J. K. Fowler, Aylesbury.

DUCKS.—First, J. K. Fowler, Aylesbury. Second, J. R. Rodbard, Wrington, Bristol.

Mr. Bailly, Mount Street, Grosvenor Square, was the Judge.

AGRICULTURAL HALL POULTRY SHOW.

THE poultry exhibition that has just been held in the Agricultural Hall, Islington, has had unusual difficulties to contend with, and, notwithstanding, has proved itself a most successful one. The time of year chosen is the one of all others most calculated to prevent an extensive entry, as adult birds are, in many instances, fast falling into bad feather now the laying season has so far progressed; and again, chickens however early hatched are as yet not sufficiently matured for public exhibition. Notwithstanding these obstacles, our readers will be pleased to learn that a collection of about three hundred pens of generally excellent birds were entered.

Black *Spanish* first drew the attention of visitors on their entrance to the Hall. In this class the lack of condition was perhaps more evident than in that of any variety in the Show—a shortcoming we were well prepared for, as this breed of poultry is considered as being the most susceptible of mischief from the effects of unfavourable weather of all others. Want of condition was consequently universal—a failing particularly developed in pen 13, which were undoubtedly first-rate, but had to content themselves with a high commendation from this cause alone. Viscountess Holmesdale took the first position in the prize list, with Mr. Wright and Mr. Rood closely competing. In *Grey Dorkings* the competition was excellent, Viscountess Holmesdale was here again successful with a most valuable pen of rosy-combed ones, adding to this achievement a second position with the pen so frequently exhibited by her ladyship last season, as to now require but little description. Although the establishing such a yard of *Grey Dorkings* must have been attended with great outlay at the outset, we believe the coming season will prove that to wrest away the Dorking laurels from Linton Park will be the most difficult of all poultry feats to Dorking exhibitors. Mr. Drewry was a very good third, and some of the highly commended pens were but little less deserving. In the Buff *Cochin* class, Mr. C. T. Bishop, of Lenton, near Nottingham had it all his own way; the pen he exhibited making it an easy “walk over” from everything in the class. We congratulate that gentleman on his possession of so excellent a pen of birds, and wish them continued success. We regret to find, however, so palpable a confirmation of a report recently current that Mr. Charles Felton, of Erdington, near Birmingham, purposed selling all his birds, and turning his attention exclusively to floriculture. The present owner, however, can well confirm the old axiom that “the wind is indeed a sorry one that blows good to none.” They are one of the best pens ever yet brought before the public. By some mistaken entry a pen of the best White *Cochin* chickens we have seen this year were shown in this class; but as the limit was to Buffs alone, they could not appear on the prize list. In the next class for *Cochins*, Any other colour, their position would have been a good one. In this latter class Captain Heaton exhibited a pen of partridge-coloured ones, of which that gentleman has reason to be proud. The plumage was not only excellent in colour, but the condition was most praiseworthy. There were many other first-rate pens of this colour, and some excellent white ones. The classes for Pencilled *Hamburgs* were a poor apology for those we met with a few years back. It is too evident we miss those noted breeders Messrs. Archer, Chune, Sharp, and Worrall. The opening is a good one just now to achieve renown by the careful culture of the Pencilled *Hamburgs*, and to restore this really useful as well as beautiful race of birds to the high position they lately held. But however great the imperfections of these classes, those for the Spangled *Hamburgs* made more than ample amends. In both instances they were quite as near perfection as any one can reasonably hope to attain. A sad misfortune to the proprietor of the first-prize Gold-Spangled pen arose from an indiscretion, against which we have so frequently guarded amateurs—viz., putting strange hens together. In this instance the master hen not only completely scalped her companion, laying open the skin of the neck for more than 2 inches, but proved herself a perfect cannibal by absolutely eating away in every direction the whole of the flesh from the back of the neck

bone. By the order of the Judges, therefore, after the skin had been carefully sewn together, this hen was removed to a place of quietude. She can never recover so far as exhibition is concerned. We mention it simply as a warning to prevent others falling into the same mistake. The *Game* classes were well filled, and with a variety of excellent birds, the Black-breasted Reds and Brown Reds being perhaps the most perfect of any. The *Game Bantams* and *Black Bantams* were very good. In the Extra variety class of these little favourites, were some perfect Black, and also White Japanese Bantams, some excellent Brown Silkies, a very unusual colour, some Frizzled Bantams, and some White Silkies. The Sebright Bantams looked below par, as is customarily the case just prior to moulting. A Sweepstakes for *Game Bantams*, the entrance monies being divided into three prizes by the rules laid down on the prize list, brought only three competitors, all of them very good. Their respective positions as to the honour of winning were easily appointed; the question of pecuniary recompence was one difficult to determine.

Neither Ducks, Geese, nor Turkeys were entered, as these classes had on this particular occasion been purposely omitted from the prize schedule.

We must not conclude without stating that the Islington Agricultural Hall affords one of the best opportunities of holding an extensive poultry show of any extant. The capabilities are indisputable. The arrangements for poultry were good, and the attention shown it was apparent. We were glad to find that at future shows a new set of pens will be in use, altogether avoiding the objection this time so evident—that the doors being so small, it was nearly impossible to take any bird out or replace it without serious injury to its appearance.

On this occasion these pens were used as the best at the moment attainable, and the difficulty will be easily provided against in future. We also suggest that had the knowledge of the Show being about to be held been more notorious, a vast increase of entries must have ensued. It is not improbable that the Islington Show will speedily rank among the highest of our poultry exhibitions.

We gave the prize list last week.

INTERNATIONAL DOG SHOW, ISLINGTON.

OUR opinion of this Exhibition will be best expressed by saying that we hope it will be annual, and that the only improvement we can suggest is that there shall be in future only two one-shilling days. A week is too long a time for a dog to be chained up, even in a place as large and well ventilated as the magnificent glazed structure in which this Show is held.

It was a great success in every way. The dogs, amounting to more than 1600, included some of the finest specimens of each variety. They were arranged uniformly on broad benches at about 2½ feet from the ground; were chained at distances uniform and effectual to prevent contests; were kept scrupulously clean; were well fed and watered; and the company was very numerous. The Prince and Princess of Wales were there on the opening day, the 25th; and then, and on the day following, we saw there a large majority of the gentlemen and ladies who are well known not only among sportsmen, but of those who are fond of superior domestic animals.

The kennel in the centre of the Hall enclosing the twelve couple of the Duke of Beaufort's hounds was of itself an exhibition. They were models of the high-bred Foxhound, unsurpassable in condition, uniformity, and that confident expression imparted by courage, and power of endurance, possessed by no dog of any other breed. The Russian Wolf-hound, swift, keen, and severe; the German Boar-hound, heavy, large, and powerful; the Slave-hunting-hound, slow but terrible, and making Englishmen sad to think of such a pursuit; Greyhounds made to cleave the wind, and in form without a heavy or ungraceful line; Pointers and Setters, prime examples of combined strength, activity, and docility; Spaniels all vivacity and courtesy; Sheep Dogs unmistakably intelligent; Mastiffs well worthy of baronial halls, and fitting helps to their warders; Mount St. Bernards hospitable in look, and of frame telling of capacity to give help, and with voice that would reach from base to summit of the Alps; Newfoundland, calm yet resolute and strong; Bulldogs, best tempered, most enduring, and most ugly of dogs; smooth Terriers of varied vivacity; Skyes all gentleness; Dandy Dinmonts ready for sport; Maltese, all ill-temper like spoiled children; Toys of all forms, and as varied in disposition; all these well represented their especial classes.

Such were the characteristics which seemed prevalent in each variety; but for the first time at a dog show, there seemed an aristocratic bearing even pervading the dogs, and telling that they were used to good society.

DOGS.

SUMMER gardens and theatres have opened their doors; the Horticultural Exhibition has fixed its tent in the Chaussée d'Autin, and has followed the canine show at the Gardens of Acclimatation. How many painters would be delighted to have before their canvass, how many sculptors before their statue, group or bust, the increasing crowd that was moved, captivated, and enthusiastic before a Terrier no larger than a man's fist! An invention, one of the triumphs to the recent Show, is the little animal shown under a glass-bell. The air we breathe is, doubtless, too coarse for its lungs. There were three we could name, that were only shown to the crowd through the transparent walls of their crystal palaces. They are no longer dogs—they are little gods. More than a thousand competitors appeared at this Show, and among them, perhaps, two hundred drawing-room tyrants. That which is microscopic and liliputian, wordly, useless, and untidy, is that which concerns and interests us most in this Show. We respect the watch dog; we love the sporting dog; we will speak highly of the Newfoundland and the "Saviour" of Mount St. Bernard, if ever the Monthyon prize should be extended to four-footed virtue; but the pocket dog, the shelf dog, the dog that on a pinch could be carried in a reticule—this is our great attraction. Greyhounds more chilly than Méry, the poet of Marseilles, and which seldom go out without their over-coat; small Terriers, clean, sharp, shining, and muscular, even their muzzles look fine and intelligent, and their ears trimmed to a point stand up provokingly; silky Spaniels; King Charles's with sensual faces, reminding one of some Roman emperor satiated with the luxury of the latter and falling days of his empire; dogs from Havannah, which would almost seem crossed with birds from their lightness, feathering, and even claws—these are our delight.

It is impossible to recognise in the importance assumed by the pet dog of an opulent family, and for which the chicken is not white enough, the cushion soft enough, the collar comfortable, nor the *bombon* sweet enough, unless each comes from the first house in the trade—it is impossible to recognise the little wretch you had seen a few weeks before hanging down its head, suffering from hunger, and furtively seeking a social position—canine Jerome Paturot!

To a certain degree the features of dogs and men change with their conditions. Suppose two similar individuals: give to one a noble, easy, and harmonious life, and direct the habitual course of his thoughts to the highest spheres; attach the other to some low and obscure pursuit, and fix him to it. At the end of a given time these two, although similar at the outset, will differ so much in expression, that even form will be affected by it to the extent that no likeness will be found between those who were at first mistaken one for the other.

Formerly at the "Barrière du Combat," and in its neighbourhood, the dogs met with were more like hyenas or wolves. The same may be said of solitary and dangerous parts of the external Boulevards. The dogs acquired the ferocity of the people among whom they lived. Every shade of the human family finds its representative in the canine species. You can find the parvenu, the real nobleman, the smooth, the rough, those difficult and those easy to please, the arrogant and the humble, the sincere and the liar.

Note that food occupies a larger space in the canine than in the human composition. Many years ago Charlet, the popular painter said, "The best part of a man is that which is like the dog." Another has said, "The better I know man, the more I like dogs."—(Translated.)

DRONES OF A DRONE-BREEDING QUEEN.

THE question which has lately been discussed in your columns as to the utility of the drones of a drone-breeding queen in spring, really lies in a very small compass. The object of producing them in anticipation of forming early artificial swarms will be found futile; and, at the same time, a heavy tax must be laid on the broken brood of flourishing hives to maintain the life of the drone population.

It was shown in a paper from a German bee-master, for the translation of which your readers are indebted to the kindness of "A DEVONSHIRE BEE-KEEPER," that fecundation takes place only in a high temperature: 70° has been the lowest at which I have observed it, and a bright sun after midday seems also essential.

This spring may be considered to have been a favourable one for testing such experiments, having been milder than the average, and yet up to this day, May 28th, the maximum temperature has been but 67°, while there have been drones from a strong hive since April 24. It may be thence inferred that it will prove labour lost in this climate to attempt to form artificial swarms earlier than the natural season of swarming, when a superfluity of drones may be insured by maintaining one or two stocks in high condition.—INVESTIGATOR.

BEE LAW.

HAVE I any legal claim to a swarm of bees of mine, which I followed to another person's garden and saw them enter a hive which contained empty comb?—S. B. T.

[We can only give the same reply that we gave to a similar query some years since. Blackstone, in his "Commentaries," says, "A swarm which fly from and out of my hive are mine so long as I can keep them in sight, and have power to pursue them; and in these circumstances no one else is entitled to take them." Indeed, if the rightful owner quickly pursues the swarm, and keeps them in sight, and any one else should hive and keep them, it would be a larceny. We believe that if the bees have been quickly followed from the hive whence they swarmed, and have never been lost sight of, their owner is entitled to follow them on to another man's land and hive them. If the man on to whose land the bees strayed took possession of the swarm, or prevented the owner from doing so, we think the owner would have a legal remedy against that man. Of this we are quite sure—no one who is honest will prevent the owner of a strayed swarm following and recovering it.]

TIME FOR HATCHING SHOW BIRDS.

WHY should I give over hatching Cochins and all other birds that are intended for show? Would not these be just as good hatched now as those that are hatched in February or March? How is it that most breeders are giving over hatching now?—INCUBATOR.

[We go on hatching. The reason why so many give up sitting their hens after this is that hens begin to lay badly, and the yards are full of chickens.]

OUR LETTER BOX.

DEATH OF HAMBURG CHICKENS (*L. O. U.*).—We think there is little doubt, from the rapid way in which death follows the attack, that poison has something to do with it. As the first brood escaped entirely and all since have suffered, and as all have been reared on the same spot, we think it likely either that some poisonous herb has sprung up or that something is thrown down that is injurious. This latter is probably accidental. The sudden death excludes the idea of disease, which is always more or less lingering. Move them to another spot.

POULTRY SHOW AT THE AGRICULTURAL HALL.—We have been requested to state that the sole management of this Exhibition was in the hands of Mr. Douglas.

BRABHA POOTRA EGG-BOUND (*T. P. W.*).—From the weight of the egg, your hen is constantly in the predicament of an egg-bound fowl, and unless you can alter this she will die. Give castor oil every other day—a tablespoonful. Feed on cooling food, lettuce, and ground oats mixed with cold water. Whenever the patient appears in pain, and about to lay, lubricate the egg-passage with a feather dipped in oil. This will facilitate the extrusion of the egg. Her present state is a certain forerunner of fatal disease if not speedily relieved.

EGGS NOT HATCHING (*B. H.*).—The fault has probably been with the hens. There was no fault with eggs that produced chickens, and the mould followed death. Stale or musty bran is bad to keep eggs in. A box or tray is the best place to keep them in, with a little dry moss in the bottom; or, if the bran be fresh, they may be put on it.

SPANISH FOWLS (*An Old Subscriber*).—We totally differ from you. As a whole we consider the second pen was better than any, except the pen to which the first prize was awarded. One of the Judges, we know, would show no partiality.

PRESERVING EGGS (*A Constant Reader*).—If you refer to page 286 (No. 107, April 14th), you will find the result of our experience.

GUAVA JELLY (*J. Ferme*).—Put the berries into an enamelled saucepan, and let them simmer for a few minutes, mashing them with a wooden or silver spoon; squeeze them through a cheese-cloth or coarse muslin until the skins and pips are dry. To every pound of juice add a pound of white sugar. Boil for a short time until the jelly is inclined to set, which is ascertained in the usual way; then pour into small jars.

INSECT EJECTED FROM A HIVE (*W. T. Blantyre*).—It is only a black humble bee which had entered the hive to steal some of the honey. The bees caught the robber and killed him.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 71.7° and 46.0° respectively. The greatest heat, 91°, occurred on the 15th, in 1858; and the lowest cold, 30°, on the 15th, in 1859. During the period 145 days were fine, and on 107 rain fell.

PLANS OF FLOWER GARDENS.

E have received recently from "G. W." and others, many plans of flower gardens, all more or less creditable, if first attempts, but none of sufficient merit to deserve engraving.

The failures in these induced us

to send them to Mr. Fish, and ask from him a few remarks generally applicable to such designs. The following is his reply:—

"All of the designers should have taken more time and sent their plans correctly drawn. I mention this because so many young artists and young writers make so many apologies for plans being made in haste, and articles written in such haste, that the haste is to be the apology for all errors and mistakes. Now, the haste is all a mistake. The public can quite well afford to wait their time and leisure if it insures accuracy. Unfortunately I cannot always command this leisure, but many of my contributions would be much more to the purpose, and more pleasant reading besides, if I could command the leisure to revise, concentrate, and improve them. I presume that the Journal's correspondents are more anxious about the results of its conductors' judgment and experience than even terse and correct writing, though the latter would always be an advantage; but that want of leisure must be no excuse for defective plans and careless writing in young beginners. I state this the more faithfully because there has been much of slovenly roundaboutism, instead of directness and concentration of thought lately. A slight circumstance will better exemplify my meaning than a laboured essay.

"My first attempt at getting into print was in the pages of the 'Gardener's Magazine,' and this secured me the acquaintance, when I was a stripling, of the noble-hearted Loudon. Passing Porchester Terrace, Bayswater, one day with an acquaintance who was somewhat dandified, stilted, and ambitious withal, I introduced him to the worthy veteran, as I had a free permission for entrance there at any time. Amongst diversified talk about Leigh Hunt, Charles Lamb, Beaton's review of Herbert's 'Amaryllidaceæ,' &c., we passed into a quiet talk about the writings and the writers to the Magazine, and my friend came out with the statement that if ever he wrote anything he must do it slapdash there and at once, and then send it off at once, for if he took time he was sure to make a muddle of it. I shall never forget the look of the keen-sighted Loudon when he replied, 'It is all very well to write quickly just as the ideas offer, but it is vastly more important to correct and revise at leisure.

No. 115.—VOL. IV., NEW SERIES.

All writings that have lived and exercised a potent influence have been the result of patient analysis and careful revision. As an evidence, single periods in Hume's 'History of England,' are known to have cost their author a whole day before he could finally settle upon the composition and the best arrangement of the words.

"I felt there was but little hope for me, though some of my articles had been written some six or ten times over, every *i* carefully dotted, every *t* crossed, and all the rest of it carefully finished. (I think I hear our worthy conductors and the printers say, 'I wish you were as particular now'.)

"Now, though, unless in some extraordinary case, the labour to me would be too much to rewrite an article or part of an article, the point at which I would arrive is just this, as showing the value of revision and concentration at an early period, that scarcely a single sentence that I intended for the public has been written without being ennobled with printer's ink, whilst the writings of my slapdash friend who did everything best in a hurry never appeared in the 'Gardener's Magazine,' and so far as I know only once appeared in the 'Horticultural Register,' and even with respect to that, I well recollect the worthy Editor of that time, the late amiable and accomplished Mr. Main, calling upon me and stating that he would be obliged if I could use the liberty of seeing the lucubrations of my friend before they were sent, as but for the bare ideas he would himself have written the article six times over before he could reduce it into anything like presentable shape.

"My days of plan-drawing, unless to suit myself, are now over, though I think I have as good ideas as ever as to the suitability of plants for definite purposes, but the lesson I wish to convey is simply this, that with plans and essays, and articles, our young friends who wish to excel should send off nothing to the press in a hurry; should turn the matter upside down, side to side, each way and every way, and in reading over what they had written, should consult not only their common sense, but the clinking as it sounds upon the ear, as they may rest assured, that everything that seems in the least obscure and inharmonious in the arrangement to themselves, will be ten times more disagreeable and obscure to a stranger reader. Many an article of our young friends, that with a little revision and careful arrangement would stand out as a gem, showing how much the younger generation is progressing over that past and soon to be passing away, is just glanced over, scarcely read, and exercises in consequence no influence.

"Facts, of course, in our profession are the chief things, and will be valuable, however coarsely or strangely communicated; but it is no less true, that facts, and axioms, and theories in gardening will gain in force in proportion to the terseness and elegance with which they are communicated, and no young writer can expect to realise that elegance and condensation in a first hurried copy of his ideas."

Upon flower-garden plans we would also observe that there is comparatively little merit in merely devising a

No. 767.—VOL. XXIX., OLD SERIES.

geometrical arrangement of beds—such arrangements can be had in endless variety by the aid of a kaleidoscope; the great merit is in planting the beds artistically.

Some persons are so mistaken as to think that the beauty of a flower garden is enhanced by the multitudinous variety of the forms of the beds. So far is this from being the case, that the beauty depends upon simplicity and just balancing both of the forms of the beds and of the colours which fill them.

Relative to form we may further particularise, that it is a great error to have many points and acute angles in beds surrounded by turf, for such points and angles can never be filled with plants. If the beds are enclosed by tiles or stone edging, such points are less difficult to leave occupied, yet even then curves and circles are always more graceful.

JUDGING GARDEN PRODUCE,

AND OF COTTAGERS' GARDENS MORE ESPECIALLY.

CONSIDERABLE discussion took place some months since about the points of merit which constitute a really good bunch of Black Grapes, Mr. Thomson, than whom it would be difficult to find a higher authority, not giving so much importance to colour as some others would like to do. My purpose, however, is not to revive this question on the mere subject of judging the merits of rival Grapes, but to open the general subject of judging horticultural produce of other kinds, in order that the anomalies which unfortunately now and then make their appearance may be fewer if not done away with entirely.

It is certainly no credit to fruit-growers as a body, that no code of laws deciding the points of excellence to be aimed at has been promulgated; while florists have to a nicety laid down the rules for guiding them on each of the subjects especially under their culture; and as now and then new members are added, like new colonies to an empire, new laws are put forth by which the new accessions have to be governed. Unfortunately, in fruits there is nothing of the kind, each judge sets up a standard for himself, and awards of an equivocal character meet the eye.

It certainly would be worth while some one putting forth a few simple rules indicating what points constituted excellence in a Pine Apple, Peach, Nectarine, Apple, Pear, Plum, &c., as well as in Grapes; and although it is not likely that any law can give all the minutiae in the exact proportions so requisite to each fruit, it is likely that amongst the multitude of councillors a more correct awarding may be arrived at.

Societies formed expressly for the testing the merits of fruits are, nevertheless, unwilling to put forth the rules they act upon in their censorship. That it would be difficult to adopt such rules in all cases is unquestionable, but something like Mr. Thomson's ten points might indicate to the public at large what to aim at in new varieties, or in growing those they already possess. As a suggestion to those who may be inclined to favour us with their views on this subject, I would suggest that the qualifications which constitute perfection might be divided into a tabular form, ten numerals being divided in such proportions amongst the various points of excellence as may be deemed most advisable. Some minor quality might only have half a point, while more important qualities may have two or three. This arithmetical way of acting is certainly the most easily explained, and carries greater expressiveness with it than any other mode that could be adopted.

It would be more difficult to embody anything like the above rules of action into the judging of collections of plants; but collections of fruit might easily be judged by some law analogous to that which governs the adjudication on single specimens. In this case a higher table of numbers might be used, and supposing every fruit exhibited was as near perfection as possible, the award ought to be given to the collection which contains the best specimens of fruits more choice than the others. For instance: Assuming 100 to be the maximum number of merit, and a basket of mixed fruits to be looked at, it would only be fair to place a well-grown Pine Apple at 90 or 95, while a Plum, even if as good as it was possible to grow one, should not stand higher, perhaps, than 15; a Peach, 40; bunch of Grapes, 70 or 80 or more; a Pear, 15; an Apple, 10; and other fruits in proportion to their choiceness and the skill required in growing them.

This is only an ideal approximation of what a really good collection might be estimated at, and the sum total of the figures added together might determine the point between rival col-

lections. Doubtless, some one may differ from me respecting the proportion above given to each fruit, and I am far from certain that it is exactly as I would give it myself when seeing the specimens exhibited; but I throw the hint out as something to found a set of rules upon.

Leaving the subject of the adjudicating on collections of plants to some one else, I will allude to another subject in which much difference of plan exists; and some for the want of any plan at all put themselves to much unnecessary trouble, and yet are liable often to decide more or less erroneously on the subjects they are directed to give an opinion upon.

It is more easy to decide a point of merit between contending objects when they are both before the eye of the censor in one place; but when he has to examine these objects at wide distances apart, and, perhaps, has to determine the respective claims of a score or more competitors, something more than merely carrying all the points of merit of each in the memory is necessary. This difficulty is much increased when the numbers are still larger, and the objects widely scattered. Notes of some kind or other are indispensable, and the simpler such notes are the better, provided they are sufficient.

A method which I have adopted for several years, and which when acting in conjunction with others I have always found them ready to adopt, although simple, may be worth recording in the columns of your Journal, for the assistance of others similarly circumstanced.

The laudable desire on the part of some noble-minded landowners in this neighbourhood, as well as of those whom I have the honour to serve, has for many years evinced itself in the giving of prizes for well-managed cottage gardens and premises, and in several instances shows of horticultural produce have been held and liberal prizes given. At these many of the products exhibited would have graced any show in the kingdom. Of this possibly I may say something hereafter, but it is more especially my purpose to treat on the prizes given for the good management of their gardens, which is a much more difficult matter to adjudicate upon than comparing the contending objects when exhibited together in a tent; and this difficulty is increased when a number of prizes of different values are given, and the gardens are scattered widely apart over a rural district, sometimes three or four together, but often solitary.

In propounding my plan I expect to be charged with a predilection for figures—a charge to which I at once plead guilty, as my plan is based entirely on figures, and in the case alluded to I rarely use any other notes. The way is this:—I place the ideal perfection at 100, and as I have never yet seen anything that in every point reached that position, I fix on the nearest number to it that the merits of the garden seem to deserve. Assuming, therefore, that the vegetable crops are good, the fruit trees healthy, hedges or fences trim, walks tidy, and the whole place in apple-pie order, a quick yet careful survey of the whole will with little practice soon point out to the inspector what number to assign to the holder of that garden, which may, perhaps, be 80, and if the two or three judges agree on the number to be affixed to the first object they inspect, it is likely the difference, even without any knowledge of each other's notes, will be but trifling throughout. Some very indifferent holdings may be as low in the scale as 30, or even less for a dirty disorderly place, while a great number will, in all probability, be represented by between 50 and 70. Still, at the conclusion of the inspection, a short time will suffice to arrange the respective positions of the whole—as A B, 85; C D, 83; E F, 78, and so on; so that whatever number of prizes may be awarded there will be no difficulty in awarding them by a reference to the table-form that has guided the judgment.

I have on more than one occasion assisted to award such prizes in which there were one first prize, two or three second prizes, and a still greater number of a third and fourth class; and also a fifth class has sometimes been added, where the number of recipients of prizes has been, perhaps, nearly one-half of the competitors. Of course each class decreases in value as it recedes downwards; and there may be some who may find fault with making so many prizetakers, but I unhesitatingly say that I entirely agree with it; for local circumstances, as a bad situation and other disadvantages, would make it hopeless for the most industrious and painstaking cottager at one place to compete with another more favourably circumstanced; but while he stands a chance of obtaining a prize he will try to do his best. I believe we have placed as many as eighteen names as winners in a fourth or fifth class.

Although the near or distant approach to 100 denoted the merit of the holding as a whole, I have not unfrequently used the same mode of figure in detail. For instance: A book, or, what is better, a sheet of stout cartridge paper, is ruled in columns for figures—one column may denote fruits, one flowers, one vegetables, one fences, and one the back premises, walks, &c., and a column for total. By entering in each column the respective number the supposed merits of each article indicate, the sum total will determine the position of the whole. This abstract way of doing the work has the merit of enabling the person who looks over the notes at last to ascertain the weak and strong points in each. Sometimes, but rarely, it may be necessary to append a few words as well; but I very seldom do this. A column for cleanliness ought, however, to be added to the above list of abstract ones, and the sum total may be the approximation of that which the whole may seem to deserve, which is better than appending the total number they will represent when all added together. The total absence of flowers ought not to depreciate the merit of the whole to the extent the figures would make it appear, for though their presence unquestionably adds much to the appearance, and ought to have due attention, still, in a cottage garden, they should stand second to vegetables and common fruits. It is, therefore, with a view of giving a just criterion of the condition of the place as a whole that, for general purposes, I would advise only one column to be used; or when more is advisable, nevertheless to let the one devoted to the "total" represent the figure it would do if there were no abstract ones.

Having extended these remarks to a greater length than intended, I have not space to say anything on cottage-garden produce as exhibited at horticultural shows; at another time, however, I hope to do so, and will explain certain features in such things which experience has taught me are not, perhaps, in every case sufficiently attended to. J. ROBSON.

THE ROYAL BOTANIC SOCIETY'S SHOW.

JUNE 3RD.

THE display of plants and fruit on this occasion was not only extensive but excellent, and another great attraction was likewise afforded by the splendid American plants of Mr. John Waterer, which will shortly attain their full perfection when they constitute an exhibition of themselves. The day was extremely warm—so much so as to render a long stay in the tents very oppressive, and the company was large, exhibiting an unusual preponderance of the fair sex.

In Stove and Greenhouse Plants several excellent collections were shown; but as they consisted of nearly the same species and varieties noticed in previous reports, it will be unnecessary to repeat the names of those which have been already adverted to. In the Class for sixteen Mr. Peed, gardener to Mrs. Tredwell, took the first prize with several splendid specimens, both as regards size and symmetry and the profusion of their bloom. Among the most striking were *Allamandas grandiflora* and *cathartica*, *Erica depressa*, *Pimelea decussata*, *Dipladenia crassinoda*, and *Tetratheca ericæfolia*. Mr. Green, gardener to Sir E. Antrobus, Cheam, was second, having his fine *Azalea Coronata*, and *Kalosanthus minnata*, the bright colour of which was very effective. Mr. Baxendine, who was third, had a fine *Coleonema rubra*, *Chorozeema Henchmanni* with an abundance of flowers, and a very fine *Aphelexis humilis rosea*.

In the Nurserymen's Class for ten, Messrs. J. & J. Fraser had a fine *Boronia serrulata*, the scarlet *Clerodendron Kämpferi*, and *Vinca ocellata*, the white and crimson flowers of which were very showy. Mr. Rhodes, of Sydenham Park, was second, and Mr. Outbush, of Barnet, third, both having in their collections good examples of *Phanocoma prolifera*.

The Amateurs' Class of ten was also worthily filled by Mr. Chilman, Mr. Wheeler, and Mr. Kaile. The first had *Aphelexis macrantha rosea* with fine large flowers, *Acrophyllum venosum* in full beauty, *Hedera tulipiferum*, and a nice *Pimelea Hendersoni*. Mr. Wheeler was second, and Mr. Kaile third; the latter having a brilliant *Kalosanthus coccinea superba*, and a nice bushy *Chorozeema Lawrenceanum*.

For collections of six Mr. Page was first; and Mr. J. Tegg, gardener to Baron Hambro', second, having, among others, good plants of *Allamanda Schottii*, *Pimelea decussata*, and *Ixora javanica*.

In the Class for six Fine-foliaged Plants the first prize was

awarded to Messrs. A. Henderson & Co., who had fine examples of *Dieffenbachia maculata*, *Dracaena ferrea*, the splashed-leaved *Alocasia macrorrhiza*, the golden variegated *Croton*, *Caladium Chantini*, *Ananassa sativa variegata*. Mr. Hutt, gardener to Miss Burdett Coutts, was second, and exhibited some of the large specimens which appeared at the Crystal Palace, such as *Latania borbonica*, *Rhopala corcovadensis*, also the curiously carved-leaved *Philodendron pertusum*, *Dieffenbachia variegata*, &c. Messrs. Jackson & Son had the Lace Plant, *Ouvirandra fenestralis*; the curious *Cephalotus follicularis*, or New Holland Pitcher-plant; and a fine *Todea africana*.

Of Cape Heaths the show was also good. Messrs. Jackson and Son took the first prize for ten, among which were *Bergiana*, a beautiful bushy plant completely covered with bloom; *florida*, also fine; and *ventricosa magnifica* and *tumida*, both of them striking plants. Mr. Rhodes, who was second, had *coccinea minor* and *ventricosa magnifica*, and good plants of other kinds.

In the Amateurs' Class for eight, Mr. Peed came in first, and Mr. Page second. Their collections contained good specimens of *florida*, *eximia superba*, *ventricosa magnifica* and *coccinea minor*, and *tricolor Wilsoni*. Mr. Baxendine was third, having also some good plants.

In six kinds the successful competitors were Mr. Chilman and Mr. Wheeler, the latter having *Bergiana*, a fine plant; and *ventricosa coccinea minor*, also very pretty.

Azaleas were not equal to those shown at the Crystal Palace and Kensington, although some of the same plants as shown at these places were recognisable. Mr. Penny, of St. Dunstan's, Regent's Park, was first in the Amateurs' Class, *Juliana* and *Madame Mieliez* being the most noticeable in his collection; whilst Mr. Green was second, the two finest in his six being *Iveryana* and *Præstantissima*, which formed a match pair handsomely grown, but not so well covered with bloom as desirable. Mr. Cross and Mr. Page also obtained prizes, and collections came in addition from Mr. Chilman, Mr. Peed, and Mr. Kaile.

In the Nurserymen's Class, Mr. Turner again took the highest position, his plants putting into the shade those of all other competitors; they consisted of *Juliana*, *Glory of Sunninghill*, *Ex-tranei*, *Chelsoni*, *Iveryana*, and *Criterion*. Messrs. Fraser were second, their finest being *Duc de Brabant*, salmon pink; and *Flower of the Day*, a fine white striped with rose.

Of Orchids, several excellent collections were shown; most of the plants, however, having already appeared at the Royal Horticultural Society's last Show, it will be unnecessary to repeat their names here.

In collections of twenty, Mr. Baker, gardener to A. Bassett, Esq., Stamford Hill, had the first prize. He had several fine *Ærides*, the yellow-flowered *Cattleya citrina*, *Trichopilia coccinea* and *crispa*, besides others previously noticed. Mr. Milford was second; among his plants were a fine *Ærides Lindleyanum* and *Cattleya Mossiæ speciosissima*, very showy. Mr. Peed was third. For a collection of eight, in which were the pretty *Ærides Lobbi*, a fine *Vanda tricolor suaveolens*, and *Cypripedium barbatum grandiflorum*, Mr. Woolley, of Chushunt, had a first prize.

In collections of twelve, Mr. Penny had the first prize, his specimens comprising a fine *Phalænopsis grandiflora*, *Calanthe veratrifolia*, and a noble *Vanda suavis*. Mr. Page was second; *Saccolabium retusum*, *Oncidium ampliatum* major with innumerable flowers, and *Lælia purpurata* being the most remarkable of his plants for beauty. Mr. Green had *Oncidium Lanceanum*, and the *Butterfly Orchis*, and received the second prize.

In the Class for six Orchids some fine *Ærides*, *Saccolabiums*, and *Cattleyas*, were shown by Mr. Wiggins, and Mr. Smith, of Syon.

British Ferns came from Messrs. Ivery & Son, of Dorking, who had a first prize for a collection of twelve, in which were included the elegant feather-like *Athyrium Filix-fœmina plumosum*, *Osmunda regalis cristata*, *Hymenophyllum Wilsoni*, *Scelopendrium vulgare sculpturatum*, and other rare and interesting kinds. A fine collection of seventy kinds was also shown by the same firm. Miss Clarkson received a second prize for her collection, which contained a very fine *Hymenophyllum tunbridgeense*, *Trichomanes brevisetum*, *Asplenium germanicum alternifolium* &c.

In exotic Ferns, Messrs. A. Henderson & Co. were first with a fine collection, comprising *Cibotium Schiedei* and *Barometz*, *Brainea insignis*, *Adiantum tenerum*, and *Cyathea vocoensis*. Fine collections also came from Mr. Lavey, and Mr. Young, Highgate, among which were some noble specimens.

Calceolarias were exhibited by Mr. James, of Isleworth, Mr.

Smith, of Syon, and Mr. Burley, of Limpsfield. Those of the latter were shrubby, and among them Prince of Wales, Dorel, and Primrose Perfection, were fine. The varieties shown by Mr. James, who had the first prize, were nearly the same as at the Crystal Palace.

In Fuchsias, the first prize was given to Mr. Gardiner, gardener to J. Stutter, Esq., Clapham Park, for Madame Cornelissen, Prince William of Prussia, Fair Oriana, Count Cavour, Rose of Castille, and Prince Imperial, all of which were in splendid bloom.

In Pelargoniums, Mr. Turner was first for twelve; Nestor, Viola, Symmetry, Desdemona, Guillaume Severyns, and Fairest of the Fair, being among the best. Messrs. Fraser were second.

In the Amateurs' Class, Mr. Bailey, of Shardeloes, had the first prize, his Lord Clyde and Glowworm appearing the most striking. Mr. Shrimpton's exhibition in the same class was also excellent.

In Fancies, both Mr. Turner and Messrs. Fraser had beautiful collections, taking the first and second places, whilst Mr. Bailey was first in the Amateurs' Class. Delicatum, Lady Craven, Ellen Beck, Crystal Beauty, Clemanthe, and Roi des Fantaisies, were a few of the finest.

Roses in pots were in splendid condition, particularly those from Mr. W. Paul and Messrs. Lane; Chénédolé, Auguste Mié, Lord Raglan, Paul Perras, and Charles Lawson, being some of the finest; and of cut blooms, extensive collections were shown by Messrs. Paul, Mitchell, Hollingworth, and Turner.

Verbenas came from Messrs. Treen, Turner, and Perry, of Castle Bromwich; Pansies from Messrs. Downie, Laird & Laing, Hooper, August, and others; and artificial blooms of the same flower from Mrs. Stoddart, of Victoria Station, which were so like natural ones that most people went away with the impression that they were real.

Messrs. Veitch had a new *Retinospora* with whitish foliage, the handsome *Cyanophyllum*-like *Sphærogyne latifolia*, *Miconia* (?) *argyrea*, and a host of other new and rare plants, which have been noticed elsewhere. Mr. Bull also contributed a large number of new ornamental plants, both as regards foliage and flower, among which were his beautiful new *Mimulus*, a fine Scarlet *Geranium* called Dr. Lindley, *Athyrium* F.f. *coronatum*, and *Chameranthemum verbenaceum*, with very ornamental silvery leaves. Mr. Williams had *Lastrea oreopteris cristata*, recently exhibited before the Floral Committee, as well as a choice collection of fine-foliaged plants. New Pelargoniums were exhibited by Messrs. Dobson, of Isleworth, and Hoyle, of Reading; one from the latter, *Diadem*, was a splendid flower, the lower petals of a fine magenta tinge. A shrubby *Calceolaria* called Bijou, said to be excellent for bedding, and of a crimson scarlet, was shown by Mr. Watson, of St. Albans.

FRUIT.

A considerable quantity of fruit was exhibited, and both as regards size and colour, the quality was excellent. A Providence Pine, weighing 9 lbs. 3 ozs., was shown by Mr. Young, gardener to C. Bailey, Esq., Aberaman, and one of 8½ lbs. by Mr. Bailey, of Shardeloes, both of which received prizes. There were also several from Mr. Jackson, gardener to Lord Scarsdale, one of which was 8½ lbs. Of Queens there were several weighing about 4 lbs. each, and some less; Mr. Barnes, of Bicton, and Mr. Horwood receiving prizes for fruit of that weight.

Melons were shown in considerable number, the favourite sorts being Golden Perfection in the Green-fleshed Class, and Scarlet Gem in the other. Mr. Simmonds, of Mickleham Hall, Dorking, had a fine Golden Perfection; and a very good Egyptian Green-fleshed came from Mr. Tegg; whilst Mr. Bailey had an Orion of 8½ lbs., and an excellent variety, the Trentham White-fleshed, was sent by Mr. Henderson of that place. Mr. Pottle, of Little Bealings received a prize for a small Scarlet-fleshed variety, and Mr. Simmons for George IV. Certificates were awarded to Mr. Bailey for Scarlet Gem; to Mr. Goldsmith for a hybrid, and to Mr. Bennett for Empress Eugénie.

Of Black Hamburg Grapes there were several very fine dishes, the best coming from Mr. Clements, Mr. Turner, Mr. Petch, of Chesterfield, Mr. Hill, of Keele Hall, Mr. Henderson, Mr. Jackson, and Mr. Pottle, all of whom received prizes. Fine baskets were also exhibited by Messrs. Hill, Jackson, and Clements. Fine bunches of Black Prince came from Mr. Hill, and good bunches of the same variety were also shown by Mr. Goldsmith.

Of Muscats, those from Mr. Turner had immense berries, but

not ripe enough; whilst Mr. Clements exhibited some of nearly equal merit, but not so large in the berry, and open to the same objection as regards not being ripe enough.

Prizes were also given to Mr. Hill for Buckland Sweetwater; to Mr. Petch for some fine Chasselas Musqué; to Mr. Drewett, Tenbies, Dorking, for White Frontignans; to Mr. Bailey for Bailey's Muscadine; to Mr. M. Henderson, of Coleorton Hall, for Grizzly Frontignans, to Mr. Hutt, and some others.

In Peaches, Mr. A. Henderson had Royal George, large and finely coloured; those from Mr. Evans being also very fine. Excellent fruit of Grosse Mignonne came from Mr. Turner; French Galande from Mr. Gardiner, and Early Dunmore from Mr. Carmichael, gardener to the Earl of Dunmore at Falkirk.

In Nectarines, the best were Violette Hâtive, from Mr. Petch, who had two dishes, both of which would have had a prize had it been allowable. Messrs. Horwood, A. Henderson, and M. Henderson had also very good dishes of the same excellent variety. Hunt's Tawny was shown by Mr. Turner, and Mr. Robinson, of Englefield. A good dish of the Downton was also sent by Mr. Tegg.

In Cherries, remarkably fine dishes of Elton and Circassian came from Mr. Henderson, of Trentham. Governor Wood, a white American sort, also received a prize. Some fine Reine Hortense were likewise shown, but unfortunately in the wrong class. They were not, however, sufficiently ripe. They came from Mr. Beck, who had also Black Eagle, good; and Mr. R. Wilson, of Warwick, had a prize for May Duke.

Large and very fine fruit of the Oscar and President Strawberries were shown by Mr. Turner; British Queen and Rifleman, by Mr. Pottle; Alice Maude and British Queen, by Mr. Horwood. Excellent brown Turkey Figs were exhibited by Mr. Smith, of Syon; magnificent spikes of Bananas, by Mr. Mart, fruiterer, of Oxford Street; and a large black-spined Cucumber, called William Brough, by Mr. Child, of Norwood.

FORCING ROSES.

It is difficult to select the six best Roses for forcing, there are so many of them; but, in addition to our correspondent "SUFFOLK'S" favourite Baronne Prevost, we may name Paul Ricaut, Edward Jesse, Géant des Batailles, Général Jacqueminot, Jules Margottin, and Madame Laffay. Of Chinese we would add Cramoisi Supérieure, Mrs. Bosanquet, and Fabvier; and of Teas, Devoniensis, Niphotos, Safrano, and Gloire de Dijon.

The success in forcing depends more on management than on kinds, and the two great secrets in management are keeping the plants free of insects, and bringing them on very gradually, never giving them a high temperature, commencing about 45°, and gradually rising to 50° at night, and never more, though a rise of 10° to 15° more will be advisable in sunshine, and with plenty of air.

Summer Treatment.—Presuming the plants have been forced or are potted now, it would be well to plunge the pots during the summer in an open sunny spot, but so that the roots do not go out of the pots, and to be well supplied with mulching and water during the summer. Flowers during summer should not be thought of or valued, and the chief attention should be given to secure healthy even-balanced wood by nipping all the stronger shoots and thinning-out any very weak spray, sturdy rather dwarf shoots to be preferred to long ones; and the nipping of the points of all may take place about the end of August, which will swell the back buds without causing them to start. In September, if the plants are strong and in rather small pots, they may be repotted into larger, using loam three parts and rotten dung or leaf mould one part, adding for Teas a little peat. Duly encouraged, the pots will be pretty well filled with roots before November. If the plants are in pots big enough for blooming, then in the beginning of September examine the drainage, remove surface soil and a little at the side of the pot, and redress with compost rather richer than the above. To have such plants in bloom in January, they should be pruned and regulated after the middle of October, placed in a shed, and kept rather dry until they are breaking, when the plants may be placed in a house in the beginning of November, where they will receive a low moist temperature. If the pots are plunged in a bed of sawdust, or spent tan, so that the roots will average 70° whilst the tops will average 45° to 50°, the plants will come on very nicely if the heads are damped with the syringe.

In pruning in summer, care should be taken not to start the lower buds; but if some of the Perpetuals are thus started in autumn—as *Géant des Batailles*, &c., and the bulk of the Chinese—and the top old shoots are merely pruned away, these young shoots will bloom in ordinary greenhouse temperature without getting any heat worthy of the name of forcing; and by this means, with little trouble and preventing blooming in summer, most of the Chinese section and the hardier of the Teas would bloom all the winter in a temperature averaging from 45° to 50° at night. In pruning in autumn, weak growers should be cut pretty close, and strong growers should have the weak twigs either removed or pruned back to a bud; the stronger well-ripened shoots should merely be stopped a little and bent a little so as to cause the buds to break regularly.

In winter water should be given only as the plants need it, and never lower in temperature than that of the house. As the leaves expand freely and the buds begin to show, weak manure water may be given alternately with clean water. Very little water will be required until the young shoots are fairly started.

Successions will be easier managed than the first lot of early ones. When the plants are done flowering they should be protected in a cold pit until they can be put out of doors in April and May.

The more air the plants have after they are started the better, provided the air is moist and mild; but in winter in very sunny days, when the air is frosty and parchingly dry, it should not play on the young foliage or buds until it has been heated and moistened; and hence, under ordinary circumstances, it will often be better to shade a little, and damp the floors and stages in such cases instead of giving a great amount of air.

In most cases a little green fly may be expected, and smoking is the best remedy, though some prefer drawing the shoots affected through weak tobacco water and syringing with clean water the following morning. There are also two opposite evils to be guarded against: If the air should be harsh and dry the leaves may have a visit of the red spider, and moisture and the syringe and not too much heat are the preventives. The other is mildew if the weather should be very foggy and moist; and the remedies are dusting with sulphur, but chiefly a little dry heat, to disperse the fog and promote a brisk circulation of air.

Does your *Cyanophyllum* stand near the heating medium and where there is an evaporating-trough? If so, and the plant get very dry, the leaves would be browned. We have also seen a plant a little affected in the same way from the sun beating on it fiercely, when the leaves were damp and air had not been given soon enough in the house.

R. FISH.

FLORISTS' FLOWERS

AT THE ROYAL HORTICULTURAL SOCIETY'S EXHIBITION.

MAY 27TH.

"*Iterum, iterum, iterumque*," one may indeed cry out at this the third great Exhibition held in the merry month of May. From the Regent's Park to the Crystal Palace, and thence to Kensington, has been the lot of many an *Azalea*, *Pelargonium*, and *Rose* this season; until at last we should think, "blushing and suffused with rosy tint" must be descriptive of them all, if they can hear the loud praises bestowed on their personal charms. "What a lip!" "What a lovely form!" "How delicate!" "Did you ever see so charming a colour?" heard on all sides from gallant cavaliers and fair maidens—bestowed by royalty, nobility, commoners, and the *bourgeoisie*, must surely have been too much for even the native modesty of *Flora's* fair subjects, and leaves but little after the detail I gave of the Crystal Palace Exhibition for me to say. What can I say, for instance, in *Pelargoniums*, but that Mr. Turner with the selfsame plants took as usual first prizes, and the Messrs. Fraser a good second—that the *Roses* of Messrs. Lane and Mr. Wm. Paul were again very nearly matched, but that the freshness and novelty of the latter's gained for him the first place—that *Tulips* and *Pansies* not coming within the patronage of the Society were absent, with the exception of some sent by one or two growers for sale—that the same seedling *Pelargoniums* were there as at the Palace, and placed very much in the same position as they were then placed?

There were, however, two collections, which, although not amongst florists' flowers, were to my mind as interesting as anything there—Messrs. Ivery's collection of British Ferns, and Mr. Salter's of variegated plants. Anything more delightfully fresh than the former collection it is impossible to conceive;

and I question if a collection of exotic Ferns would exhibit more beautiful and varied forms than did this of native species. Messrs. Ivery are so well known for the magnificent collection in their possession, that we need hardly say that rarity and excellence of cultivation characterised their productions. I noticed amongst them especially the following:—*Asplenium marinum*; *Allosorus crispus*; *Athyrium Filix-femina apuense*, crispum, depauperatum, diffusum, Fieldiae, Frizelliae, molle incisum, multifidum, plumosum, thyssanotum; *Ceterach officinarum*; *Cystopteris fragilis*; *Lastrea Filix-mas crispa, cristata, incisa, Jervisi*; *Osmunda regalis*; *Polypodium dryopteris*; *Polystichum angulare proliferum*; *Scolopendrium vulgare crispum, endiviatifolium, fissum, multifidum, ramosum, corymbiferum majus*. In Mr. Salter's collection of variegated plants were *Funkia undulata variegata*; and variegated forms of *Acer negundo*, *Hedera helix*, *Ruta graveolens*, *Scrophularia nodosa*, *Hesperis arabidæfolia*, *Tussilago farfara*, *Salix caprea*, *Spirea ulmaria*, &c. This collection was also a hardy one, and thus suggested how much may be done in adorning our gardens with this section of ornamental-foliaged plants.

As there are many who are interested in the *Pelargonium* I give here the names of the winning plants, although it is nearly a repetition of those of the Crystal Palace. Mr. Turner was first in 12 Show *Pelargoniums* with *Fairest of the Fair*, *Roseum*, *Desdemona*, *Bacchus*, *Rose Celestial*, *Guillaume Severyns*, *Sunset*, *Lady Taunton*, *Viola*, *Empress Eugénie*, *Candidate*, and *Picnic*; the Messrs. Fraser second with *Carlos*, *Desdemona*, *Sir Charles Napier*, *Sanspareil*, *Roseleaf*, *Leviathan*, *Mr. Mar-nock*, *Etna*, *Ariel*, *Festus*, *Saracen*, *Empress Eugénie*. Amongst Amateurs—for Fancies, Mr. Weir, gardener to Mrs. Hodgson, the Elms, Hampstead, was placed first with *Delicatum*, *Lady Hume Campbell*, *Madame Sontag*, *Emily*, *Carminatum*.

In Fancy *Pelargoniums* Mr. Turner was again first with *Cloth of Silver*, *Roi des Fantaisies*, *Lady Craven*, *Clemathe*, *Delicatum*, *Ellen Beck*; and the Messrs. Fraser second with *Aeolus*, *Celestial*, *Clara Novello*, *Cloth of Silver*, *Bridesmaid*, and *Multiflora*.

Messrs. E. G. Henderson and Mr. Bull sent collections of new hybrid *Mimulus* and *Zonalis Geraniums*. Amongst the Messrs. Hendersons' were some pretty tricolor-leaved varieties—*Italia Unita*, *Sunset*, *Mrs. Pollock*, and *Countess*. Mr. Standish again had his new Japanese *Clematisses*; but novelties were, as you justly said last week, not very numerous.

What, then, about the Exhibition as a whole *per se*, and as compared with the others of the season? This must be a matter of taste; but for beauty of appearance I question whether the palm will not be universally given to the Royal Botanic Society. And as to the plants there can be but little difference: the same exhibitors and the same plants are to be noticed at all of them, and arrangement must decide the preference. It seemed to me to be a great mistake, for instance, not to have had a slight covering of tiffany over the plants. It need not have been an awning; but a semicircular canopy springing from the back of the stages, and just reaching over the plants, would have greatly improved their appearance; for not only did the light deaden the colours, but the immense size of the building dwarfed the plants. A slight tiffany shading would have neutralised these effects. The wideness of the nave gave an excellent opportunity for moving about, which was increased considerably by the, to my mind, unfortunate arrangement of separating the music *in toto* from the flowers. If one band had been stationed at the majolica fountain, and the other left in the gardens, it would have enhanced the Exhibition vastly, instead of, as it did completely, cutting the matter in two.—D., Deal.

REDISCOVERY IN ENGLAND OF TRICHOMANES RADICANS.

Will you afford me space in your Journal for the announcement of my having discovered the *Trichomanes radicans*, or European Bristle Fern, in the neighbourhood of the Snowdon range in North Wales?

This may be interesting to your readers who take pleasure in the cultivation of Ferns, as there is no record of its having been found in England, Scotland, or Wales since the year 1782, in which year it was found at Bingley, in Yorkshire.

The only recorded habitats of this beautiful Fern which bring it within the category of British Ferns are some few places in the lake district of Ireland and in the county Wicklow.

For reasons which you will readily understand I am unwilling to indicate more precisely the habitat I found.

The plants, of which I secured several young specimens, are remarkably fine, the fronds in many instances being from 12 to 18 inches in length; and as a justification of my having disturbed it I may say that it was very abundant in the spot in which I discovered it.

I shall be glad, if you think it necessary to verify my statement, to send you a dried frond.—JOHN F. ROWBOTHAM, *Town Hall, Manchester.*

SAM SLICK'S GARDEN.

I MUST add my testimony to that of "A FRIEND TO FLORICULTURE," in your Number of the 12th of May, when he alludes to the flower garden and grounds of the Hon. Mr. Justice Halliburton (the renowned Sam Slick), at Gordon House, near Isleworth. I accidentally visited this place in the summer of 1862, and I would advise both lady and gentlemen amateurs to ask permission to do so, which will be courteously granted.

The arrangement and planting of the flower-beds is a perfect study, and I will in a future Number venture on a brief description. The success of these gardens is, I am told, entirely owing to the taste and industry of the fair owner, who with very limited assistance (two men and a boy, I understood), continues to keep in perfect order 6½ acres of flower and kitchen garden.—A CONSTANT SUBSCRIBER.

NEW BEDDING GERANIUMS.

THERE are very few of your readers who do not regret the absence of Mr. Beaton's articles from your Journal. Those of us who are interested in the cross-breeding of flowers, especially bedding plants, have felt disappointment as week after week your Journal has appeared on our tables, and no lively pleasant page with the well-known signature at the bottom. Though personally unknown to me, I for one desire to express my regret at the blow by which, I hope only for a time, Providence has deprived floriculture of one of its most learned professors. It is not many months ago that Mr. Beaton announced in your pages his possession of a variety of seedling Geraniums of all colours except yellow, that he hoped to obtain even that, and as yellow as a buttercup, and that already he had one of a true orange. It was by the aid of his very accurate article in your Journal, descriptive of the bedding-out at the Crystal Palace, that last August I was able to find out all the novelties which he had sent to be tried there. That same article, by-the-by, sent me on a fool's errand, for no sooner had I seen the Crimson Minimum and Lord Palmerston, especially the latter, than off I went to the nearest nursery in hopes of obtaining both. But I was told at once, "Oh! you are too fast, sir, by a year or two; those Geraniums are only sent for trial, and won't be in the trade for, perhaps, a year or two." That same Lord Palmerston, however, has appeared this year, and if I mistake not, I have also the Crimson Minimum of the Crystal Palace. I bought it last year of Messrs. E. Henderson & Co. under the name of Minimum Nosegay. Lord Palmerston is a magnificent Geranium. There was, I believe, only one bed of it last year at the Crystal Palace, on the east side of the Rose Mount—one of the round beds—it caught my eye directly. Its colour is very bright, and the trusses are absolutely immense. For large beds and where a strong and attractive effect from a distance is required, it is the finest of the whole breed. I confess, however, to a weakness in favour of a more dwarf style of growth. If such a truss as Lord Palmerston could be obtained on a more prostrate-growing and shorter-jointed Geranium, I should say that, so far as that colour is concerned, we had reached perfection. Now, Mr. Beaton mentioned a seedling of his which, as far as my memory goes, was to beat anything—Cybister or The Tumbler was, I think, the name. I want it for breeding from. Now, who has that? Is it only in Mr. Eyles' or Mr. Gordon's keeping yet? I do not see it in any catalogues. The Crimson Minimum is the Geranium which Mr. Beaton himself recommended to Mr. Fish in preference to Stella; and it is superior to Stella in my opinion, because though the colour is much the same as also the truss, the habit is very much shorter-jointed and dwarfer. In the mass, therefore, you would have more flowers.

From the nursery to which I went for the purpose of getting Lord Palmerston and Crimson Minimum—viz., Messrs. Carter

and Co.'s, Crystal Palace Nursery, I have received this spring—Lord Palmerston, Spread Eagle, Merrimac, and Miss Parfitt. The last three, especially Spread Eagle, are apparently very dwarf. Can any one tell me if any of these last three is Cybister or The Tumbler? I know nothing about their flowering capabilities or their habit of growth; but they appear, as most of the new Nosegay section do, to have a close relationship to the Crimson Ivy-leaf Geranium.

And now I have a secret to reveal which, if this should meet Mr. Beaton's eyes, will, I hope, give a fillip to restoring his health. The desire of cross-breeders, in one direction at least, has at last been produced. It may be seen at Messrs. J. & C. Lee's, Royal Vineyard Nurseries, Hammersmith. Having an hour to wait for the train at Kensington, I strolled into Messrs. Lee's delightful nursery. In one of the smaller span-roof houses devoted to bedding Geraniums I saw, I could scarcely believe my eyes, a white variegated Geranium with a white flower. "Five guineas for a plant?" "No, sir, it is not for sale."—F. M. ADEY, *The Cell.*

[The Editors will be readily believed when they say that no one feels more deeply than they do the illness which has withdrawn Mr. Beaton from their side. They hope it is only a temporary withdrawal, for Mr. Beaton is better in health, yet some time must still elapse before he can resume his pen.—EDS. J. OF H.]

FAILURES IN A VINERY.

HOT-WATER PIPES REQUIRED FOR HEATING A VINERY AND CUCUMBER-HOUSE.

I SHALL be obliged by your giving me your opinion on an alteration I intend making in a vinery, and also on the addition of a Cucumber-house to vinery. Three years ago I built what was intended for an "orchard-house" 20 feet long by 12 wide, lean-to, brick sides and ends, fixed roof, ventilation at front and back. Inside the house is 8 feet high at back, 3 feet in front, with a sunk path in the middle 2 feet wide, leaving the borders 5 feet wide. Partly from the ground being raised outside and the house built on very low ground, the surface of the border is quite 2 feet below the level outside, which I believe makes the border cold and damp. In May, 1860, I planted three Black Hamburgs at the end, which is nearly north by west, the house facing south-west. The Vines have made good growth. This is the first year of bearing, and I have about forty bunches. Many of the berries have the spot, and are becoming gangrened, to remedy which I would propose in September carefully lifting the Vines, which are inside the house, and there is no means for the roots to go outside; to remove the soil down to the stone rubble, &c., at bottom of border, to place a hot-water pipe there, well covering it with rubble; and to remake my border, and have it as high as the outside ground; also to make a border outside in front for the roots to run through the arches. I presume the mischief arises from want of root-action.

In 1861, at the south-east end, I planted three Muscat of Alexandria Vines, but they have made but very little growth. Would they answer better planted in the centre of border as Sanders recommends? In the event of my moving them, would it not be best to plant them in front, to do away with centre path, and to put it at back of house?

At the north-west end is a brick pit with six lights, so I cannot allow the Vines to run out there; and at the south-east end I wish to join the Cucumber-house. The Cucumber-house to be 12 feet long by 9 wide, with a kind of hip-back or half span-roof, glass in the front under the eaves, and brick at the back, and glass end at south-east—path 3 feet wide in centre, border on each side 3 feet wide, to be heated by hot-water tank. What size pipe must I use to heat Vine-borders, and how many pipes to heat the house? Also, what pipes to heat Cucumber-house?

I wish one boiler to do the whole heating, and to be placed at the back of the two houses. Will you be kind enough to advise me? What I require to heat is not of any extent, and another thing to be borne in mind is that the gardener has never had experience with hot water.—EDGARLEY.

[We do not think that your Vines need have suffered if the ground had been properly drained, though it will be an advantage to have the inside ground equally high with the outside. We should never think of planting Muscats in a mere orchard-house. They could only ripen in a fine sunny summer and autumn. Your Hamburgs may be suffering as much from deficient venti-

lation as deficient root-action; but if you are satisfied that the latter is the cause of disease, the lifting and replanting will be in their favour, and the same may be said of the Muscats. We do not know if you intend your house for forcing early. If so, the pipes below the border will be a great advantage, but if you let your Vines come on nearly naturally you will require no pipes below the roots. If you raise the inside border we presume you mean to raise the house as well, as from 5 to 6 feet is no great height. It matters little where the Vines are planted, whether at the front or more in the centre, with pipes below. We would prefer the centre, though it is of little consequence.

For early forcing you would need two four-inch pipes for bottom heat, and at least three four-inch for top heat. Less would be required if you commenced in March or the end of February. As to boilers, the simplest tubular or saddle-back will suit your purpose. Our own opinion is, that for continuance there is little difference between boilers if properly set and properly wrought. We have little faith in the wondrous tales some people tell us when under the influence of enthusiasm. If you want Cucumbers in winter and early spring you will need two four-inch pipes for bottom heat, and the same for top heat; if in May or so three-inch pipes will do. Your best plan would be to have a boiler sunk deeper by a foot or 18 inches than you wish the pipes for the border to be, take the one flow-pipe to an open cistern, and from that take a pipe to all the places to be heated, each of these joining the return-pipe to the boiler.]

LIFTING APPLE TREES FREQUENTLY.

WILL it be possible or convenient to you to let this meet the eye of "C," who wrote a very interesting account of his dwarf Apple orchard, which was published in No. 636 of the COTTAGE GARDENER AND COUNTRY GENTLEMAN, December 4th, 1860? I will accept it as a great kindness if he will favour me with the information—which will, no doubt be valued by other readers—whether the mode of lifting his trees biennially after about nine years' experience is still satisfactory, and if they bear well with it, but more particularly whether it has prevented canker from appearing in his Ribston Pippin Apples; the main drift of my writing is to learn that.

Last autumn I planted a portion of my garden with a number of Apples and Pears on the Paradise and Quince stocks, and amongst the number one Ribston Pippin. I wished to have had more, but was afraid of the canker, for a few years ago I lost a nice Hawthornden Apple tree from the same cause. The Ribston has never been grown in this neighbourhood that I am aware of; but as the Hawthornden cankers in my soil, I fear the same will happen to the Ribston, unless a periodical lifting of the tree will prevent the disease, as some assert it will. My soil is nearly like that of "C.'s" garden. If the annual or biennial removal of that valuable Apple will prevent the canker in wet soils and induce fruitfulness, it is information which ought not to be hidden—when practically proved—from us Lancashire people, who cannot grow to perfection the finer fruits, such as Peaches, &c. An answer to my questions I doubt not would be very valuable information to many amateur gardeners whose garden soil is wet, and the major part is I believe so. As I wish to fill all available space in my garden this autumn, will he please to state, now that his trees must be by this time pretty well grown, whether 3 feet by 4 is sufficient room for his dwarf trees? Mine is a small garden, and I want them kept in little compass. I never had the pleasure of seeing a full-grown orchard of dwarf trees, so I have but little idea what space they require when matured.—A. Q., *West Houghton*.

RAINFALL AT LINTON PARK, KENT.

A CORRESPONDENT having inquired how the rainfall of the past three months corresponds with that of similar periods in former years, I have been induced to give the following table, taken from a register kept here, by which the deficiency of the rainfall in the present season will be easily seen. I may further add that the rainfall of May up to the 29th has been 1.59 inch, and falling in eight days. The greater part of this fell on the 19th, 20th, and 21st, and was accompanied at that time with a very cold north and north-east wind, which was also strong and proved very hurtful to vegetation. The windward side of forest trees in full leaf has been bruised and destroyed,

and now looks as if scorched; delicate things, even when sheltered, suffered more or less. The cold continued several days and nights. The night of the 25th-26th May was unusually cold, the thermometer sinking as low as 35° in the garden, and in some exposed places in the park it was quite a frost. There have been various changes of wind, that from the S.W. not having been always so mild as could be wished. The general opinion is that the rain of the 20th only benefited the more hardy vegetation, the cold by which it was accompanied neutralising its otherwise useful properties. At the present time (the 29th), the atmosphere has more of a summer character; but extreme changes have been so common of late that it is impossible to say what may next follow.

JOHN ROBSON.

JOHN ROBSON.

HAS THE CLIMATE OF ENGLAND CHANGED?

WE are induced to take up this subject from the fact of hearing very lately, whilst in the west of England, more than one landowner express in most decided terms his opinion on the deterioration of the weather—an opinion that we conceive to be very injurious to the best interests of the country.

In this note we intend to confine ourselves to an investigation of the temperature. In a former article, on the rainfall of England (*Mark Lane Express*, April 28, 1862), we showed that there had been no increase in the annual amount of rain during the past forty years.

The following mean temperatures of every year since 1815, grouped in ten-year periods, exhibit no signs of any change: there are merely the ordinary fluctuations, some above and some below the average, that are evident in all statistical tables of this nature, where the series is not long enough to obliterate the effect of individual exceptional cases.

In this and the subsequent tables the whole period—viz., from

1815 to 1860, has been divided into four ten-year periods and one six-year group. By including ten years, the extreme jumps of temperature between one year and another partially disappear; whilst the five mean groups are ample to show that no radical change has taken place.

We might have gone back much further, but were unwilling to admit any evidence on which we could not place the most perfect trust; and thermometer readings anterior to the commencement of our table we did not consider so accurate as those of the later date.

The mean temperature of the ten years from 1815 to 1824, both inclusive, was 49.8°, for the next decade it was 50.4°, for the following 49.2°, then 49.8°, and for the six years it was 49.0°. Here we perceive no difference to any material amount, and we might for all practical purposes consider the readings to be identical, which, were the series sufficiently long, no doubt they would be.

But, it may be remarked, if the winters have become warmer and the summers colder, no difference may be shown between the yearly average temperatures of one ten years and another; although the effect of such a change in the seasons would be of the utmost moment to the progress of vegetation. True! and to guard against this error, let us examine each month, taking the mean of every ten years for each month of the year; we shall then see if the individual months have altered at all, or if, on the contrary, each has received, on the average, its normal amount of heat.

Table showing the average monthly temperature in ten-year groups, from 1815 to 1860 inclusive:—

Years.	Jan.	Feb.	Mar.	Apl.	May	Jun.	Jul.	Aug.	Sep.	Oct.	Nov.	Dec.
1815 to 1824...	38.1	40.1	43.2	47.2	53.0	58.2	61.1	61.5	59.0	50.8	45.5	40.4
1825 to 1834...	37.3	39.9	43.0	48.0	54.6	60.2	64.0	61.6	57.2	52.1	43.9	42.5
1835 to 1844...	37.8	38.8	42.4	45.9	53.2	59.1	61.5	61.9	56.9	49.5	43.9	40.0
1845 to 1854...	39.2	39.7	41.2	46.2	53.1	59.0	62.3	61.0	56.6	49.5	44.3	40.4
1855 to 1860...	38.1	37.8	41.3	45.7	51.9	60.0	62.4	62.4	57.1	51.4	41.7	39.2

Looking over this table, the eye fails to discern any approach to a descending tendency, or, indeed, to discover any periodicity whatever in the results. Here is a number above, there one a little below the average, but nothing to indicate any regular march either of increase or decrease.

If it be necessary, let us make out another table, in which we will calculate the average temperature of the seasons for each decade. The following will then be the statement:—

Table showing the average temperature of the seasons, in ten-year groups, from 1815 to 1860 inclusive:—

Years.	Spring.	Summer.	Autumn.	Winter.
1815 to 1824.....	48.5	57.4	57.1	41.3
1825 to 1835.....	43.7	59.6	57.0	40.2
1835 to 1844.....	42.7	57.9	56.1	41.6
1845 to 1854.....	42.4	58.1	55.7	41.3
1855 to 1860.....	41.4	58.1	57.0	39.7

Here is a striking uniformity between the mean temperature of one decade and another. Were the series sufficiently long, we have no hesitation in saying that even these slight inequalities, which exhibit no law amongst themselves, would disappear, and the number expressing the temperature of either season for such a period would be identically the same for all averages including the same number of years. It is needless to remark that, in compiling tables of this kind, the most rigorous exactitude is required: one false reading would throw a doubt over the entire table, as would also a single inaccurate observation.

To sum up in a few words, the only conclusion we can arrive at is, that there has been no alteration in the temperature of this country, nor have the seasons changed their characteristics. "Seed time and harvest" have never ceased nor exhibited any tendency to encroach one on the other; the laws of meteorology are as stable as those of astronomy, and the regularity of the heavenly bodies is not more strictly maintained than that of the recurrence of the phenomena of climate. We shall be glad to see the popular error, that the winters are warmer and the summers colder than they used to be, fade and die out; such a belief is calculated to do much harm, and therefore, on the ground of expediency, should be thrown aside, even if the bare recommendation that truth always brings with it were not sufficient to secure a place in all men's minds.—(Mark Lane Express.)

ALYSSUM SAXATILE COMPACTUM.

DURING the month of April, when riding on one of the omnibuses which run from the town of Leeds to the out-townships, I saw in one of the villa gardens which line the road some plants of *Alyssum* quite different from any which I ever saw before; their dwarf growth and close compact-flowering habit was quite the reverse of the plants in my garden at home. Thinking that the soil had something to do in the matter, and not being able to make inquiry on the spot, I allowed the thought of them to pass out of my mind. Since then, when on a visit to Shipley, near Bradford, walking with a friend past the Shipley Nurseries, and having a few minutes to spare we walked into the nurseries. Here, again, I met with the dwarf plant, labelled *Alyssum saxatile compactum*, in full flower, the flowers quite covering the leaves, and forming an object very pleasing to look upon. The grower of hardy herbaceous plants will not make a mistake in growing this early spring-flowering plant, and the bedder will do well to grow this shrub in his beds at a season of the year when they are naked and dull. It is a plant which must be a favourite, even if it to some growers be an old favourite. I would have secured some plants, but Mr. Dean was engaged with some customers, and the short time allowed me having rapidly flown away, I was forced to hurry off empty-handed.—RUSTIC ROBIN.

HEATING GARDEN STRUCTURES.

(Continued from page 401.)

FLUES.—In houses of some size—say 36 feet by 18 feet, where a forcing temperature is required to be kept up, two flues are required; the one, a single flue, takes the front, and the other makes two or three journeys along the back. The flues here are constructed of brick dished in the middle like a press-brick, but the hollow penetrates fully an inch into the brick. Three of these placed on edge form the sides of the flue. The bottom of the flue was formed of bricks 15 inches square by 2 thick, and these were laid on a single thickness of common brick at the joints of the flue-bottom only. These bearers were laid on a foundation of bricks levelled with the plumb-bob. The covers for the flue were 15 inches square by 3 thick, dished out like the side bricks, and would hold when filled nearly three pints of water each. The flue at its entrance into the house was formed for a yard of fire-bricks at the sides and top, and then fire-tiles were used for covers a yard further, which part was entirely covered by flagstones to prevent the heat from scorching the plants in the vicinity. Bear in mind this was the front flue passing along both ends and the front of the house. The furnace was 2 feet 3 inches long, 1 foot 3 inches wide, and 1 foot 3 inches high above the grate. It was built entirely of fire-bricks, and the top was arched. The top of the furnace was level with the bottom of the flue, so that the smoke or heated air rose 1 foot 3 inches from the fire, after which it went at a dead level, and rose no more until it entered the chimney. The flue at the back of the house was similarly constructed, only it went three times along the back, and like the front flue was covered with dished bricks. In the hollows water was poured when a moist heat was desired, and pieces of stone were placed therein, on which pots containing Orchids were placed. I have seen some very fine plants of *Bletia Tankervilleæ*, and other old-fashioned Orchids, grown in this manner, and French Beans were regularly forced, the pots being placed on a wooden trellis made on purpose. Some of the finest *Amaryllises* were grown on the front flue, and no place was ever more calculated to suit them than this. The plants were in the midst of a moist atmosphere when growing, and literally baked when at rest. The position was marked out by Mr. Herbert, of Spofforth, near Wetherby, as a fit and proper place for that tribe of plants, and I believe the greater part of the plants were had from him. I regret to say that they have lately been thrown away as unworthy of a place amongst so many fine plants as we have at present in our hothouses.

Now, those flues were made about 1820, the houses being, I think, completed in the autumn of 1821; and they cost £9 11s. the pair, labour and everything being considered. Five of such houses with similar flues were put up at the time, so that the cost of the heating apparatus alone was £47 15s. The range was divided into four Pine-stoves and a vinery. There were Vines in three of the other houses.

Fine Grapes were grown in those houses, specimens of Black

Hamburgh weighing 4 lbs. per bunch, the berries as large as moderate-sized violet Plums, and quite as black. Pines, too, were grown there of large size, some Providences weighing 6, 7, and 8 lbs. commonly, and in one instance 9 lbs. 11 ozs.; Queens, Montserrat, Antiguas, Sugarloafs, Black Jamaicas, and others, were proportionately large, and this thirty years after the houses were built. The flues had not cost more than 10s. each annually in sweeping and repairing during that period—that is, on an average. The account-books verify this statement, and I may finish the Cr. part of the business by stating that the same flues were in successful operation in 1858, the last time I saw them, and plants certainly did come out of the houses that year which won first prizes at the autumn show of the York Horticultural Society. In the Dr. account of the flues in question, I find £26 10s. worth of coals consumed annually, and £15 worth of tanner's bark, or, in all, £41 10s. as the cost of heating. The coals were brought by water some sixty miles, and the tan came nearly twenty miles by the same means. In the thirty years seven flues had burst, destroying something each time, and the soot in the flues took fire times out of number, and subjected a plant or two to a roasting temperature. I mention these flues to show what a flue was when they were in their prime, when gardeners considered how to build them so as to meet their wants.

Pausing for a moment, I will tell of another kind of flue erected in 1830 and now doing good service. At this period they ran all their flues horizontal, and not as some people do now—rising from the fireplace with one end on the floor and the other on pillars, as if the flue were too proud to lie and too idle to stand. Well, the flue in question was built of common bricks placed on edge; the bottoms and covers were clay tiles made on purpose, 2½ inches thick. On the top of the flue a brick was laid edgewise parallel with each side of the flue, and on those bricks a flagstone for a shelf or table on which to place the plants. In the stone shelves openings were cut so as to let the heat out of the chamber below into the house, 3 inches by 1 foot, and a foot apart. By this plan the house was not soon heated nor the plants roasted. I have seen good Grapes—nay prize Grapes—grown in the house where this flue worked.

But a flue as it is built now, what is it? More frequently a failure than a success. I have had a flue boiling water in a saucepan after it has traversed across one end of the house, melting lead where it entered the house, whilst at the other end next the chimney it was neither warmer nor colder than a lamp-post—so much for the absorbing powers of brick. And all that heat to keep out an ordinary winter's frost! I have grown Ferns, stove, and greenhouse plants with flues, ripened Grapes and other fruits with them, and given satisfaction to my employers; but I do not like flues for several reasons—a few of which are: They consume more fuel, require more attendance than hot-water boilers, are soon hot and soon cool, dry the atmosphere too much (causing it to be saturated at one end with moisture, whilst it is like that of a malt-kiln at the other), emit sulphurous vapours inimical to vegetation, are liable to get out of repair, and are sure some time or other to blow up, or something will happen to cause unpleasantness to all concerned. Besides, when a flue becomes aged the mortar decays and the smoke is apt to follow a new route. See your plants are suffocated, and you feel that you are to blame for it—neglect has done it! A gardener cannot always find time to examine a flue; and, if he has the time, I very much doubt whether he can detect a flaw in time to save his master's plants. I never could. I never could tell when a brick was mouldered away out of sight at the back of a flue, nor tell when an ill wind would rise. I like flues at a distance, for I never felt sure of carrying my plants successfully into specimens nor my fruit to maturity, and when confidence in one's self is gone the worst place to look for something to cause a return of it is a rickety old flue. We very often hear it stated that flues are cheaper than hot water, and are more easily tended—that is, any sort of a bungling fellow can mind a flue furnace, but it requires one with some skill to attend a boiler. This is the reverse of fact. A flue furnace requires double the care of a boiler furnace, and this peculiarity alone is a point in fact much against flues.

I remember having fourteen flues to attend to, and I know there was trouble enough with them, and at times as many as twenty-two fires fell to my lot. In winter those fires were to look at every morning at six o'clock, to stoker; if out, to light, which with the aid of a labourer occupied at least half an hour. Then the temperature of the houses must be seen; but it often had to be taken before the fires were touched—that is, before

six o'clock, a piece of extra work falling on the young man. Of course a minimum temperature must be had at that time within a few degrees, a few too low being better than many too high; but if the temperature was wrong the head-gardener was sure to come blustering, though he was silent as most when all was square. Then some of the fires would want touching up again before breakfast, some requiring an extra touch, and then you could get your breakfast as content as a king. The fires would now do until noon, or in bright days until 3 or 4 P.M., when they must be revived, and worked up into going order by 6 P.M. At 8 P.M. in ordinary weather they were made up for the night. In severe weather they require attendance at 10 as well; but in very severe weather a poor fellow must sit reading marks on the wall in the dark, with no light but a fire, and no books but your own purchased out of a paltry 10s. per week, after satisfying the craving of the stomach of a growing lad. You must trudge knee-deep in snow to look at the conservatory fires half a mile away; and then after a walk home meeting nobody, and seeing as little, you begin to muse, until, startled by the cry of a bird as solitary as yourself, you hasten to throw a few coals upon the fires without inquiring whether Pines, Vines, and the plants are too hot or too cold, and thus you manage to get to bed when your watch marks I.

So much for flues and the little skill and attendance they require. The cost of a flue depends on circumstances. Prices of materials vary in different parts of the country, and carriage forms an item that cannot well be estimated. The size and the purpose for which the flue is intended is another consideration, but to heat a house 21 feet by 15, to be kept at greenhouse temperature, it is necessary to have one flue all round, or at least along two ends and one side, or in front, if a lean-to, and by all means all round if a span.

Fire-grate, doors, and damper	£0 19 0
Fire-bricks	0 8 4
Common press-bricks for flue, chimney, &c.	0 16 8
Bottoms and covers for flue, tiles or flags	0 12 6
Chimney-pot	0 2 6
Ash-pit digging	0 3 0
Mortar, sand, and slip for fire-bricks	0 8 4
Foundation for flue, materials	0 5 0
Mason's account for building	1 1 0
	<hr/>
	4 16 4

The estimate given above includes carriage of materials, some of which had to be brought ten miles. All the materials are of the best description, calculated to last the owner's lifetime, and to cause little expense in repairs beyond sweeping, &c.

In building flues, it is necessary to secure a good draught, and that can be done better at the fireplace than at any other point along the flue. Allow the fire to rise at least 1 foot into the flue from the furnace. The heated air will rush into the flue, and as it will not descend, there is no danger of the flue not drawing; but if the flue be level with the fire, and then rise gradually from that point, the smoke and heat will take the highest point, and that being the top of the fireplace as well as the top of the flue, it escapes at the door. True, it may burn if the wind blow in the same direction as the flue runs, but if the wind be opposite, it will blow down the chimney, and the smoke will come through the ash-pit rather than go up the flue, and if the latter is not smoke-proof the house is soon full of injurious gases.

Botching up a flue out of old materials, and giving an estimate of the cost as a fair sample of the cost of a flue is preposterous, and an estimate framed on bargains is equally deceiving. I have made a flue for less than £1 to heat a greenhouse; but everything belonging to it was lying about as lumber, and it only needed labour and brains to turn this to advantage.

Common pot-pipes 6 inches in diameter do very well as a flue for small houses, and, of course, small fires, for should the pipes get too hot they will crack like a clay chimney-pot. The furnace may be made in the ordinary way, fire-bricks used for a yard or so of flue, and then the pipes neatly connected to it; the joints of the pipes should be made up with mortar, and the elbows contrived so that they can easily be taken out, and a piece of wire run down the pipes with a kind of holly brush attached to it, so that you can clean out the flue in an hour without troubling sweeps or masons. A house 21 feet by 15 could be heated in this way for £2 14s.—viz., glazed six-inch pipes, £1 4s., fire-door and grate, 15s., bricks and mortar for furnace, 8s., labour, 7s.

But the cheapest kind of flue I ever saw was made of six-inch horseshoe drain-tiles placed on the bottoms as they are in land draining, the joints plastered with mortar on the outside

only, the tiles having previously been steeped in water to make them adhere to the mortar, and this only cost some 35s. or 37s., I forget which, for furnace, flue, chimney, and everything. This flue heated a house 18 feet by 11, and worked satisfactorily. Amateurs mostly covet such simple contrivances; their enthusiasm often helping them over troubles, and they make as little to do about many attentions as we gardeners make much. Their aim is to suit their ideas to their pocket, and ours is to suit our master's pocket to our craft. An amateur measures his pocket; he has £20, £30, or £50, that he can spend on a hobby, he is fond of flowers, takes a fancy to an orchard-house, likes to grow his own Grapes, and considers how he can do this or that for the least money. If he can build a house for £20, and heat it for less money than a gardener, or if he can plan so as to have a house twice the size of his neighbour's for the same money, securing the same or better advantages, why should he not have them? By all means, I reply, have your wish, but still to argue that your plan would suit Mr. So-and-So's gardener is absurd. Mr. So-and-So, perhaps, objects to your plan, he does not care for a few pounds if he can secure increased gratification, nor grudge a few shillings if he is able to say—"My plants are as good as those of anybody else, and a little better." There is no parallel whatever between an amateur and a gardener, for with one it is a question of obtaining the most for the money, whereas it may be the same with the other, but oftener, "I want the best house that can be had, at least, I shall expect to have things grown up to the mark, for £50, £100, or £1000," and for a gardener to begin patching up a house after this notice would be as bad as making a halter to hang himself.

I have seen an amateur, a clergyman, with his miniature greenhouse heated by a small stove costing but 25s. On inquiring the reason for having so paltry an affair, when he could afford a better, he was pleased to reply, "You know I am no gardener. I will just feel my way with this small house, and when I understand how to manage it, I will (D.V.) have a larger."

"Many clever people, let me tell you," continued his reverence, "go too fast; they begin running up hills, and are blown ere they reach the summit. Had I put up a house 50 feet long, stocked it with fine plants, and had one of your grand hot-water apparatuses, I should have wasted more money than I could spare, by killing plants for want of knowing how to grow them, and taken up more time than my parochial duties will allow."

"But your house, although small, is well built, the squares of glass large, and provision made to admit abundance of air. Why not have a good heating apparatus?" "There you are beat," replied the rev. gentleman. "I will tell you. When I understand this tiny thing I may put up a vinery, and then this house will make a two-light Cucumber-house, and a four-light Melon-house, by putting up a partition. I shall then have a boiler to heat the whole; but if I were to have a boiler for this small house, or even a flue, it would be a waste of money. I had the stove by me worth 25s., and so suited my mind to my means." I was mute.

"Could you tell me of a good boiler," resumed he, "one that will not consume too much fuel? I thought of having a flue, but flues are nasty-looking things, filling up a good deal of space, requiring an annual coat of whitewash, and very often are leaky after all. There are too many joints in flues for my fancy, and the smoke they emit is not very pleasant when the wind blows it into the drawing-room, and covers newly-washed clothes with smuts; besides a flue will not consume coke without attendance every two or three hours, nor cinders from the house, and keep in all night without some small coal mixed with them. A good boiler of small size that will do for hours without attendance, and burn anything, is a desideratum, especially for us amateurs who are as fond of having a good produce as most folk."

This homely conversation ended in my suggesting a plan of my own, as there was no boiler likely to suit him. He had a good boiler behind his kitchen fire, and to have the "grate bars cast hollow," would double the heating power. At one side of the fire place was the oven, and on that side the boiler was to be pierced for the pipe conveying water from the grate bars, and the return-pipe might enter the grate bars on the other side where it would be cast square, but hollow. He was a good mechanic, and could turn his hand to anything, so the making of a model was a pastime. The bars were to be 1½ inch, ¾-inch hollow, four bars at bottom, 5 inches in depth,

and 1 foot 6 inches long; to be cast at any iron foundry for £2, finding own model, and fixed for £1 more. This was calculated to heat 250 feet of four-inch pipe, and do the cooking business besides, and give hot water for household purposes into the bargain.

By this simple contrivance the well-paid artisan could have his greenhouse, vinery, or whatever he pleased without a costly, because separate, heating apparatus. A shopkeeper in the murkiest thoroughfare of London might take the slates off an attic, replace with glass duchesses, cover the floor with some waterproof material, convey an inch-pipe, lead or iron, from the kitchen boiler below, take it through the ceiling like a gas-pipe, or in the chimney, bring a return down alongside it, and then connect it to as many feet of three or four-inch piping, reckoning one superficial foot at a temperature of 212° to heat 50 cubic feet of space to a temperature of 60°. He might have his *Limatodes rosea* and *Lycaste Skinneri* in this attic-house, Ferns if he chose, Roses when he pleased, Violets all the winter, and his "better half" a few hours of delightful recreation daily, without spending more in a year by going to Sydenham, or in 10s. 6d. bouquets at Covent Garden, than would give at home what is sought abroad. Anybody can make a boiler after this model for themselves; but any of the trade patenting it will be prosecuted with all the rigour of the instructions my reverend benefactor gave.

It may be as well to say that I left that part of the country shortly after, and the clergyman was soon after preferred, so that I am inclined to think the suggestion would not be carried out. But it is there, and if I ever can manage to find time to make a model, and have it cast, I will do so, if it be for nothing but to prove whether water will not heat as soon in an horizontal as in an upright tube, which I have proved over and over again from the fact, that a horizontal tube will make as much steam in as little time as an upright.—G. A.

(To be continued.)

A DAISY-ERADICATOR.

WITH reference to your remarks to correspondents on the 2nd inst. under the head "Destroying Daisies on a Lawn," you give but little hope of exterminating these pests.

Having succeeded in utterly eradicating every one on a lawn of half an acre, allow me tell you how I accomplished the task.

With the assistance of a common blacksmith I constructed a simple but most effective Daisy-drawer (as annexed) which enabled me with the least possible trouble to draw out by the roots every Daisy, wild Marjoram, Plantain, &c., on the lawn, and they were not a few. The drawer is pointed, and enters the ground easily in moist weather, and the weed being caught in the fork is drawn out cleanly and more effectually than by any other implement I ever saw, and without making a large hole or disfiguring the turf.—C. B.

MUGWORT USED AS A CURE FOR EPILEPSY.

THE common English name for the plant is Mugwort; the botanical name is *ARTEMISIA VULGARIS*, and the local Irish names are *Bofulan ban*, *Bofulan liath*, *Bofulan liagh*, *Liath lus*, *Mongach measga*, *Buachalan* (but not the *Beanchalon buidhe*, or Ragwort), and *Buafanan*. It is known by these several names in the different localities in Ireland. The Gaelic name is *An Liath-lus*, and the Welsh names *Bydiawg lwyd*, and *Caweraidd lwyd*. It is important that we give the several names by which the plant is known in different places; and the following is a very brief description of it. It is an herbaceous perennial plant, dying down to the ground at the end of the season and spring-

ing up from the roots in the spring. In its young state it closely resembles the garden Chrysanthemum, and belongs to the same Linnæan class and order—Syngenesia superflua; natural order, Compositæ. Leaves wing-cleft, flat, cottony underneath. Bunches single. Florets of the circumference five. Receptacle naked.

Mr. Shephard, Bettystown House, Drogheda, says: Take three or four large roots, fibrous roots included, and the stems and leaves if in season—that is, the roots only in winter, and the whole plant, roots, stem, and leaves, in the spring and summer. The whole, when cut up into very small pieces, should be equal to a good large handful, and boiled in a quart of beer, three cupfuls to be taken three times a-day (we suppose this should be read, a cupful to be taken three times a-day), morning, noon, and night.

In hunting up the medicinal history of this plant, we find in Withering's arrangement of British plants that a drachm of the powdered leaves was given four times a-day by a Dr. Home to a woman who had been affected with hysteric fits for many years. The fits ceased in a few days. In this patient assafoetida and ether has been given to no purpose. The powdered roots have been recently prescribed with success in epilepsy on the continent; and he says, notwithstanding these favourable reports, Mugwort is rarely employed in England, and has been rejected by the London College. Wormwood and Southernwood, which are highly aromatic and medicinal plants, belong to the same genus—*Artemisia*, and may lead many to a discovery of the Mugwort, which grows plentifully in waste places, waysides, and amongst rubbish.—(*Irish Farmers' Gazette*.)

ACACIA SQUAMATA (SCALY ACACIA.)

Nat. ord., Leguminosæ. *Linn.*, Polygamia Monœcia.—A remarkable erect-growing shrub, branched, and having the appearance of being leafless. The branches are slender, terete, flexuose, somewhat glaucous. The leaves are of the form and thickness of the branches, stiff, slightly divergent, about an inch long, bearing in their axils a scaly bud. The branches thus appear to consist of a series of terminal buds seated in the forks of dichotomous branches; the apex of the leaves is slightly

recurved and mucronate. The racemes are short, and bear two or three globular heads of deep yellow flowers; these spring from the axils of the leaves, and issue from the bud of boat-shaped brown membranous scales. This interesting plant was introduced by Mr. Drummond, from the Swan River, and was first raised and blossomed by Messrs. Low in 1848. Like the other Acacias, it blooms in early spring.—(*Gardeners' Magazine of Botany*.)

VINES STARTED WITH A TEMPERATURE TOO HIGH—FORCING STRAWBERRIES.

IN the middle of March when my Vines were started, I changed the kind of coal after a few days' firing. That last adopted was considerably hotter than the other, and the water in the boiler and pipes became overheated: consequently the expansion-chamber which stands at the end farthest from the furnace boiled over and steamed the house. This happened before the eyes had burst. They, however, rapidly developed themselves within a few days, but subsequently to the shoots attaining the length of from 4 to 6 inches, they have almost stood still, and where bunches did show they have since shrunk and dropped off. Will you oblige me by stating whether you consider this to be the effect of a scale, and what is the treatment they should have now? A few bunches remain at the top of the house where the shoots are more vigorous and healthy.

Will you also say when Strawberries for early forcing—say to be ripe in March, should be struck in pots, if thumb-pots are best for this purpose, and if Carolina superba, British Queen, and Sir Harry, are good for the purpose?—D. P. B.

[If we are not mistaken, your Vines are an example that all such things as bursts and extra excitements, are seldom attended with any ultimate advantage. We have heard people boasting in how many days they would have Vines in bloom, from the period of lighting the first fire, even in January, and the result was a good deal similar to the case you state so clearly. Had your Vines received similar treatment in January, it would have been still more unfortunate for them, as the stored-up juices of the plant would have been sooner exhausted. The better the wood of Vines is ripened, the more time will they require to break healthily, and that from heat rising very gradually, beginning at 45°, and not going beyond 60°, until every bud has pushed 1 or 2 inches. If, as we gather from your statement, the Vines were not beginning to move when they had this hot steaming, then the injury would be the less, such as you will get over next season. If the Vines had broken, though only half an inch, the hot steaming might have settled them for the season, and injured them for a year or two to come by deranging the whole system of the plant.

If the vinery was merely shut up, and the buds not beginning to move, we do not think that the Vines should have suffered as you state, from one or two of such steamings, and then we should conclude there was something in the roots, and in the condition of the wood, to account for the standing-still of the Vines. But if from your first-rate fuel there was much of the boiling-over at the reservoirs or cistern, and the house was thus frequently filled with hot vapour, then that alone would account for the condition of the Vines. The buds through the stimulus of the hot vapour would break prematurely, and would go on pretty well, so long as they fed on the stored-up nourishment of the stems, but when that was not followed by a reciprocal reaction, there would come by degrees a want of support, and the shoots would stand still. In our young days we once saw the working of some Vines in January, where a high temperature was maintained inside, and the outside borders where the roots were, were frozen, and the same stand-still took place, and the Vines in bloom dropped their flowers, even though the gardener, but too late, had the borders covered with spruce branches for want of anything better. Much the same thing we suspect happened with your Vines, though in a less degree; the extra excitement worked up the nourishment in the stems before there was a reciprocal action between roots and branches.

Now, as to the remedies. Prevent over-heating by care and a suitable damper; no water in pipes ought to be near the boiling-point, 180° or so is quite high enough. If there is anything like danger from steaming, provide a larger reservoir to admit of the necessary expansion; and as to the Vines, water the border with water at about 90°, if at all dry, and keep the house cooler than usual, lessening the excitement. From 55° to 60° will be high enough at night, with plenty of air in sunny days, so that the heat should rise little above 80°, and if bright sun distresses the Vines at all, throw a little water over the glass with a syringe, the water being just coloured with whitening. In order to promote equal growth, stop the vigorous shoots near the top of the house, and this will throw the vigour back into the weaker shoots. If we understand your case, we think these measures will make your Vines all right next year.

The plants of Strawberries to have ripe fruit in March should be laid in as runners in small pots—say 60's, as soon as you can

obtain the runners. The small pot is filled with soil, set beside the old plant, and a runner fastened into it, with a pebble or anything else, and the soil is watered until the pot is filled with roots, the runner in its pot is then detached from the mother plant, set in a shady place for a few days, and then potted into a six-inch pot. The future treatment has often been given. Good established plants should be got into a house commanding fire heat about Christmas, and the heat being gradually raised, you may expect fruit in the first and second week of March.

We do not think much of Carolina superba for such early work, neither would we advise British Queen or Sir Harry, unless the fruit was wanted in the end of March, or the beginning of April. Keens' Seedling would be better, and a few of the Black Prince would come in earlier still.]

THE REPLY TO "A GARDENER'S LOVE LETTER."*

O, MY Sweet William, it quite gave my Heart-a-choke to hear how your Love-lies-bleeding, cut up, as it were, by the Cissus of Cupid, and all for me. And now it is my turn to confess that, although Phlox of fellows have followed me before, and only the other day there was a Gay-zany-here, who actually dashed his Bachelors-buttons because I wouldn't have him, all of them seem but Sickly-men and dwarf Dalliers compared with Yew, William; and as for their love-letters, "La-burn-'em!" says I to mother, as soon as ever I read your beautiful offer. Pa-sly as usual, immediately inquired about your resources, and seemed much pleased with what you said about being master of the Mint; and he then observed that he always preferred the Gold and Silver-edged sorts as Bedders. He seems to have had a presentiment that you would propose to me, as he remarked to mother, "The first time he Cedar I knew he'd Aster." He desires me to tell you that if Any-gal-is is worth having, or any Gal-hardier than another, you've Pick'd-her, and also that he wishes us good luck in the nursery department. Please to send me some more of your Lad's-love, and believe me to remain until death (long may it be, my William, before I go out Bill-burying with you), your Everlasting—ROSE-MARY.

P.S.—Forget-me-not.

[Since the above was received we have had another reply; but as its verses are not quite equal to those of Anacreon we will only quote from it six lines, which will suffice to demonstrate the writer's feelings are not forced.

"Thou master of the Mint and Thyme,
Come now and make me Holly thine.
Come now, and do not be so Sloe,
For you shall ne'er have cause to Rue.
Believing me for ever, deary,
Your most affectionate—ROSE-MARY."]

CROSS-BREEDING STRAWBERRIES—THE AMERICAN SPECIES.

MOST persons suppose that all Strawberries will hybridise with each other, and there has not been any European or American author but what has inculcated this erroneous idea, until I controverted the fiction *in toto* in the *Horticulturist* of January last, a truism which I had very long since recognised, but had not previously found time and a suitable opportunity to fully enunciate. It is now two hundred and fifty years since the first interchange of European and American Strawberries, and during this entire period there has never been produced a single hybrid between the species of the two hemispheres, nor between the three species which are natives of Europe. The six North American species blend sexually with each other, and the two South American species blend sexually with each other, but these two sections present a normal aversion to any hybridisation with those of the Eastern hemisphere. Messrs. Hovey, of Boston, attempted such hybridisations twenty-eight years ago; Professor Huntsman and myself have tested them for a similar period; neither could succeed. No such hybridised seedlings have been presented in America, in France, or in England, and all pretences of producing any such hybrids now are delusive notions arising from an ignorance of normal facts.

The characteristics of the six North American species are acidity and great productiveness; and the characteristics of the *Fragaria grandiflora* and *chilensis* of South America are large

* See JOURNAL OF HORTICULTURE, May 26.

size, sweetness, and perfume. Of the one hundred and twenty selected varieties of the *F. virginiana*, *iowensis*, and other North American species, there are but about twenty-five now under cultivation in our gardens which have sweetness predominant, and only fifteen which have perfume or aroma; and these are the best selections from thousands of seedlings during the last thirty years.—(Mr. W. R. Prince, at American Pomological Society.)

PORTRAITS OF FLOWERS, PLANTS, AND FRUITS.

ZOSTEROSTYLIS ARACHNITES (Cobweb *Zosterostylis*).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. This Orchid is peculiar to Java and Ceylon. Petals dull green, lip yellowish dotted with purple.—(*Botanical Magazine*, t. 5381.)

COCCOLOBA FLATCLADA (Flat-branched Lobe-berry).—*Nat. ord.*, Polygonaceæ. *Linn.*, Octandria Trigynia. This remarkable plant was discovered at Wanderer Bay, Solomon's Islands, by Mr. Milne, during Captain Denham's voyage of H.M.S. "Herald." "Being throughout the year covered with innumerable blossoms, generally interspersed with bright red, and finally dark purple berries, we regard this plant as one of the most interesting acquisitions of our gardens. It is readily multiplied from cuttings."—(*Ibid.*, t. 5382.)

HIGGINSLIA GHEISBECHTII (Gheisbecht's Higginsia).—*Nat. ord.*, Rubiaceæ. *Linn.*, Tetrandria Monogynia. Probably a native of New Grenada. Leaves rich velvety green above, and reddish-purple beneath. It is a handsome stove plant.—(*Ibid.*, t. 5383.)

ANGULO A RUCKERI (Mr. Rucker's Anguloa—blood-coloured variety).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. The original species is a native of Columbia. This variety is in the possession of Messrs. Rollisson, Tooting. Flowers yellow and crimson.—(*Ibid.*, t. 5384.)

PLEUROTHALLIS REYMONDI (Reymond's Pleurothallis).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Native of the Caracae, at an elevation of 6000 feet above the sea. Flowers purple but small.—(*Ibid.*, t. 5385.)

ASPIDISTRA PUNCTATA ALBO-MACULATA (White spotted-leaved Dotted-leaved Aspidistra).—*Nat. ord.*, Liliaceæ. *Linn.*, Octandria Monogynia. Native of China, imported by Mr. Bull, Plant Establishment, Chelsea. Flowers in the greenhouse during February.—(*Ibid.*, t. 5386.)

FEERN-LEAVED CHINESE PRIMROSE.—Raised by Messrs. E. G. Henderson & Son, Wellington Road Nursery. It is crimson-flowered, and has the unusual property of coming true from seed.—(*Floral Magazine*, pl. 149.)

HYACINTH SAN FRANCISCO.—Yellow-flowered.—(*Ibid.*, 150.)
AZALEA SURPRISE.—Called also *Madame A. Verschaffelt*. Flowers pale pink, rather frilled, conspicuously blotched with deep crimson on the upper segment.—(*Ibid.*, 151.)

AURICULA PRINCESS OF WALES.—Raised by Mr. C. Turner, Slough. Purple self with white paste.—(*Ibid.*, 152.)

MIMULUS MACULOSUS.—Three varieties from Mr. Bull's Nursery, Chelsea. *Charm*, *Mamel*, and *Sparkler*, all bright yellow, variously spotted and blotched with crimson.—(*Florist and Pomologist*, ii., 73.)

PEAR BRITISH QUEEN.—Raised by Mr. Ingram, Her Majesty's gardener at Frogmore. Large, pyramidal, golden-coloured fruit, excellent for dessert, ripe in October. Had a first-class certificate from the Royal Horticultural Society's Fruit Committee.—(*Ibid.*, 80.)

THE FEAST OF APPLES.—There are many holidays observed by the Russian Church, but the most prominent are the Honey Festival, on the 1st of August, and the Apple Feast. Both are peasant festivals, and much regarded—at the former the honey is blessed, and at the latter the Apple. No Russian ever thinks of eating an Apple before the 6th of August (old style), when the day's ceremony has blessed the fruit, a restriction which must be attended with very good results in a country predisposed to cholera. The Cathedral of the Repose, Uspenski Sahor, was the first entered by Mr. R. S. Graves, author of a "Yatching Cruise in the Baltic;" and the congregation was pressing forward to the priests, who stood in front of the Ikonostast. The leading priest, most magnificently dressed, held a gold and diamond-studded cross to all who presented themselves to imprint upon

it their eager kiss. On his right stood another, who had dishes of blessed Apples on a table before him; and we observed that all who had kissed the cross received an Apple.—(*Scottish Farmer*.)

HESPERIS MATRONALIS FLORE PLENO.

DOUBLE ROCKET.

It may not be out of place, seeing that after the last bad season for what are called bedding flowers both north and south of the Tweed, and more especially as there have been indications among writers in the latter part of the kingdom of a desire to fall back upon some of the old-fashioned hardy flowers, and as this new periodical will most likely be read by every lover of flowers in the west of Scotland—to bring before their notice a few hardy flowers of real merit, which have been put aside or forgotten in the rage for ribbon-borders and masses of tender flowers, but which with a little care throughout the year would give a fine display of bloom from early spring to late autumn. A great variety of these could be named, both in colour and in height, and in their season of blooming, but I will only select one at present—the Double Rocket, as during this month (June) it will be in bloom, and there being variety enough in itself both in colour and height to form an excellent contrast. It is possible that it may still be found in some out-of-the-way corner of the herbaceous border, and if so, it will require no recommendation from me. As for the cultivation of it, no gardener worthy of the name requires to be informed; but I would just ask them to try a ribbon, of say the first row dwarf double white; second row of crimson; third, purple; fourth, tall or French white; or say a row of the double yellow *Barbarea*, and then a row of French white. Or, perhaps, a bed of any convenient length, and say 5 feet wide; centre row, tall white; next two rows, purple; and two outside rows dwarf white, 1 foot from plant to plant, or any such arrangement, and I am sure it will amply repay the trouble next June.

To the uninitiated, I would say, if there are old plants to begin with, cut down the flower-stems to about 6 or 8 inches from the ground as soon as the flowers are beginning to fade; stir the soil round the plant, and top-dress with a little light soil, say old rotten leaf mould and sand, in equal proportions. In the course of two or three weeks plenty of young suckers will have been formed from the old stem, and will be striking roots for themselves. These should be taken off, and either planted under a hand-glass or cold frame, in light sandy soil, in a shady corner of the garden, and watered carefully. If not rooted when taken off, they will soon strike in a cold frame or under a hand-glass. Cuttings may also be made of the flower-stems that are left, after cutting off the flowers; but in general, the suckers from the root will be sufficient. The plants thus obtained should be planted out in common garden soil, with the addition of a little old rotten manure in autumn, or if not convenient then, they may be kept over winter in a cold frame or nursery-bed in the garden, and planted early in spring, not later than March. If planted in what is called an herbaceous border, the dwarf white should be placed in the front row, and the others in the next. If the border is wide, the dwarf in the second row, and so on with the others; and, by a little care, they will make a fine display next summer. The only enemies they have are snails, and a small green caterpillar, which makes its appearance about the beginning of April in the centre of the young flower-stems, and its whereabouts is known by its drawing together the leaves. It should then be hunted out and destroyed. A little sharp sand placed close round the plants when planted, will help to keep the snails at bay.—ALEXANDER STORRIE, *Whiteinch, Partick*.

[From the first Number of "The West of Scotland Horticultural Magazine," which promises well.]

ICE TRADE AND MANUFACTURE.

THE trade in ice is now one of great and increasing importance. Ice has always been esteemed as a luxury in warm weather; and this early led to the storing of it in winter and preserving it for summer use. The Greeks, and afterwards the Romans, at first preserved snow, closely packed in deep underground cellars. Nero, at a later period, established ice-houses in Rome, similar to those in use in most European countries up to the present time. But these means were not enough to supply the luxurious

Romans with ice for cooling beverages, and they actually established a trade in snow, which was brought to Rome from the summits of distant mountains.

The trade in ice in this country has, until lately, been very limited, having been chiefly confined to the supply required by a few of the first-class fishmongers and confectioners—the private residences of the more opulent families being furnished with ice-houses, in which a sufficiency is kept for private use. But the North Americans have started a trade in this article in their own cities, which has extended to Europe and Asia, and has, in an incredibly short space of time, attained a surprising magnitude. The export of ice from America was commenced about 1820, by a merchant named Tudor, who sent ice from Boston to the West Indies. After persevering against many losses, he succeeded in establishing a trade with Calcutta, Madras, and Bombay; and now not only is it sent in vast quantities to those places, but also to Hong-kong, Whampoa, and Batavia. About fifteen years since, the Wenham Lake Ice Company commenced sending ice to this country from Boston, which is the great American port for shipment of this material; and since then, not only has there been a continually increasing supply, but the success of the Company has been so great as to tempt others into the market, and many cargoes now annually come from Norway and Sweden.

In America the ice is chiefly collected in the neighbourhood of Boston, Philadelphia, Baltimore, Washington, and New York, and the lakes which supply it form no small part of the property of those whose lands border thereon; these have all been carefully marked out, and the right secured, so that, when the winter comes, and the ice is formed, the harvest begins with great regularity. The ice is cleared from snow by means of an implement called the plane. An ice-plough, drawn by horses, and driven by a man riding upon it, is then made to cut deep parallel grooves in the ice, and these are again crossed by other grooves at right angles, so that the whole of the surface is deeply marked out into small squares, measuring a little more than 3 feet. A few of these square blocks being detached by hand-saws, the remainder are easily broken-off with crowbars, and floated away to the ice-storehouses, which are usually built of wood, on the borders of the lake. Some of these are of vast dimensions, and contain vaults of great depth; the walls are double, and sometimes treble, being altogether as much as 4 feet in thickness, and having hollow spaces between to render them nonconductors. The blocks of ice are covered up with sawdust, a layer being placed between each tier of blocks. Many of these ice-houses are made large enough to hold from 40,000 to 50,000 tons of ice. When fully stored, a large quantity of dried marsh-grass is trodden in upon the top, to the thickness of several feet, and the doors are then securely closed. The domestic consumption of the United States in 1860 had reached very nearly one million tons, and the export trade exceeds 280,000 tons per annum, of which England takes, on an average, about 20,000 tons, costing £20,000. The total value of the ice which is stored in America has been computed at £900,000, and if to this we add the ice-trade of Norway, Sweden, Russia, which, from the slight data we possess, is estimated at £600,000, we have the astounding fact, that a value of one million and a half sterling is added to a comparatively small body of water by the mere act of freezing.—(*Chambers's Encyclopædia*.)

DOES THE OWL DESTROY GAME?

Does the owl kill any other quadruped or even biped except the mouse, and, perhaps, in certain stages of its growth, the rat?

The velvetten Dogberrys of our game-preserves have ever answered such queries as the above in the affirmative; but as to the cause why these sober effusions are not generally accepted we know not, save that a little prejudice may influence the evidence of the aforesaid keepers.

But whether this be so or not, certain it is, that I am not influenced otherwise than favourably towards our useful pest-exterminator—the owl, even though I am about to charge him with habits not calculated to promote his well-being generally. I say habits, yet we have no proof that it is habitual with him to destroy game; and did I think that the incident I am about to relate as having occurred beneath my own eye, would cause any to meditate future injury to him, I would certainly regret having been influenced by the wish to assist in arriving at a proper conclusion as to the real nature of his doings in this way.

At that calm time, the close of eve, I recently halted in my walk round the mansion to fondle the warder dog, when suddenly the noble fellow attempted without ceremony to spring from my hold. Upon looking up I saw passing close by a hare followed by two leverets, each about six weeks old, at the same instant a light object fell with unerring swoop upon the hindmost. A cry of pain was heard, and before I could recover my surprise the dog had approached the two objects, when away flew the white one, "an owl!" Two minutes had not elapsed before again a similar cry of pain shot through the air; away again bounded the dog to repeat his rescue of the second mortally wounded leveret. I availed myself of the opportunity of inspecting the leveret without the dog having touched it. It was dead, each leveret had a wound about an inch in circumference precisely in the centre of the back. Doubtless, the owl has young owlets whose requirements incite the old ones to adopt unusual practices in their efforts to procure food.—W. FARLEY, *Digswell*.

WORK FOR THE WEEK.

KITCHEN GARDEN.

HOEING, forking, and surface-stirring to be diligently persevered in; the advantages derivable therefrom are manifold: weeds are exterminated, slugs disturbed and destroyed, moisture retained at a time when it is most needed, and a healthy action kept up between the roots and the atmosphere, which is the principal cause of the success which follows these operations. Trenching vacant ground to be prosecuted where required; and if manure is wanted on the ground about to be planted it is best to lay it on the top after trenching, and then fork it in. Let all green refuse be removed from every part, and either dug in or taken to the char-heap. *Asparagus*, to maintain the strength of the grass for next year no more of the produce should be cut. Late and close cutting is one of the principal causes of weak grass. *Cauliflowers*, the plants that are now forming their heads to be watered and mulched with short litter, this will cause them to come close and compact. *Celery*, continue to plant successional crops into trenches; take up the plants with as much earth about the roots as possible, and by no means shorten any of the leaves. Immediately after the planting give them a good soaking with water. The earliest crops to have the earth loosened about their roots, as the frequent waterings they require harden the surface and prevent them from receiving the benefit which they otherwise would receive from future waterings. *Cucumbers*, those on ridges to be supplied with plenty of water, and liquid manure occasionally. *Endive*, make a sowing for the main autumn crop. Plant-out a few of the early sowing; keep them watered until they get root-hold. *Herbs*, some of them will shortly be fit to cut for drying: the best time for doing so is just as they are coming into flower. *Lettuce*, keep a quantity tied-up for blanching. Make another sowing in drills where they are to remain. *Spinach*, sow a few rows for succession; if the weather continues dry water the drills before sowing, and again after covering them. Plant-out the forwardest Brussels Sprouts, Green Savoys, and Buda-kale; if the weather keep dry the roots to be dipped in a puddle consisting of earth and water, worked up to the consistency of thin mortar, before being planted. *Sea-kale*, the buds on the old roots to be thinned-out considerably. Young seedlings, if any, to be thinned, and the thinnings planted if required. *Saladings* of all sorts are now in great request; look well to successional sowings, and see that they all have copious supplies of water to induce crispness and mildness.

FLOWER GARDEN.

During the continuance of dry weather frequent waterings to be given, not only to the recently-planted trees and shrubs, but to the bedding-plants, annuals, &c. In watering it will be better to give the soil a good soaking once or twice a-week in preference to a mere sprinkling on the surface daily, which has a tendency to make the surface bake; mulching, whenever practicable, to be adopted, as well as damping the foliage of newly-planted things each evening. Go over the beds frequently, and keep the young shoots of *Verbenas*, &c., nicely regulated and pegged down until the ground is fairly covered, after which the shoots may be allowed to grow more freely. *Carnations*, *Picotees*, and herbaceous plants, with the taller-growing bedding plants, to be staked and tied-up to prevent injury from high winds. Remove suckers from *Roses*, and give them plenty of manure water to keep them in a healthy and vigorous state. Mildew is some-

times troublesome at this season, and no time should be lost in dusting the infected plants with sulphur; for if neglected the evil will soon spread and destroy the foliage, and ruin the plants for blooming in autumn. Mulch Dahlias with rotten dung, and give plenty of water in dry weather. Propagate Pansies by the side-shoots.

FRUIT GARDEN.

The recent hot weather has brought out the insect tribe in abundance, and they must be met with timely remedies. A good garden engine or syringe should be kept in frequent use amongst Currant bushes infested with aphides and honeydew. Fruit trees on walls would also be benefited by a good syringing. A fumigating on a large scale is sometimes practised by collecting a good heap of rubbish on the windward side of the fruit trees, and when ignited the great smoke is productive of good effects. Where practicable the Strawberry-ground to be thoroughly soaked with water; such is the excessive heat of the weather at present, together with the drought, that without a liberal supply of water the fruit will most probably ripen prematurely. Thin the young wood on wall trees to the quantity required for bearing next year, and nail or lay it in carefully, taking care that the tender shoots are not bruised. Pinch the points out of the young shoots of Fig trees when they have made five or six joints. By such means more stocky and fruitful wood will be obtained.

GREENHOUSE AND CONSERVATORY.

The sprinkling of the soil and the paths to be often resorted to during bright weather, and a thin screen of some kind should be thrown over the roof or portions of it from eleven o'clock to nearly three. This will retard the specimens already in bloom, and prevent too great a demand on the energies of the plants. When arranging the plants let there be no crowding, but allow every specimen full place, especially hardwooded plants. Large specimens of the hardier kinds of greenhouse plants may now be placed in a sheltered situation out of doors. Those that require repotting to be kept in the house after shifting until the roots get hold of the fresh soil. Attend well to young stock, which will now be growing freely; keep the shoots nicely regulated and shaped as may be necessary to secure well-formed specimens, and use every care to give them a moist atmosphere, sprinkling them overhead early on the afternoons of bright days, and reducing the air; but we may repeat that young stock will be better in pits and frames than in greenhouses. Specimen and choice plants when nearly done blooming to have the faded blooms picked off, and to be well washed with the syringe, to be then placed in a cool shady place to recover themselves before potting, which, as before advised, should on no account take place until a fresh growth has commenced. Spare room, if any, may be occupied with Fuchsias and softwooded plants for the conservatory.

W. KEANE.

DOINGS OF THE LAST WEEK.

Tanks.—The weather still very parching, for though rains have fallen not far off, none have come our way. The 30th and 31st ultimo looked promising for a drenching, but all passed away, and the same may be said of the 3rd inst., though the barometer is gently falling. Why mention these matters? Just because they have so much to do with our doings, as water is now the most important matter with us, and not only are gardens, but the villagers all round here, are feeling the want of water very much. We cleaned out our large tank yesterday, so that when rain does come, we will have plenty of clear, sweet water. We found some small cracks in the side, which were fresh pointed with cement, furnishing a hint that large tanks of great length would be the better of a wall across them in the middle as a stay, as when the water is low there will be less or more of pressure from the earth outside. This tank is, inside measure, 6 feet deep, 24 long, and 12½ wide. There is only about 9 inches above the ground level, surface of the water all exposed. The ground dug out was clay, the surrounding ground clay. The walls are 14 inches thick laid in cement, with the exception of three courses or so at top, which are 9 inches, and covered with rounded ridge-bricks. There are besides piers outside at the four corners, and two on each side. The bottom was concreted, then a layer of bricks in cement covered with tiles in cement, and then a coating all over bottom, ends, and sides, of cement. We mention these particulars to meet the wishes of several correspondents, who see the necessity of saving the water that falls from their houses, and just to hint that it would be false economy to build such tanks with walls of four-inch

work, as two friends propose doing, if the tank is to be any size at all. Nine-inch walls will not be too much for a tank half the size of the above. For many years, though fully exposed, we never saw the slightest mark of a crack in it; but then it was more supplied with water than for the last two years. The pressure of the clay when swelled with water outside was, therefore, more resisted by the water inside. In such circumstances, as an improvement in such a long tank, we think it would be true economy to have a wall across the middle from side to side, with openings below for the water, or an arch or a couple of arches abutting on the sides, would have the same strengthening effect. The walls are also built perpendicular, but we question whether strength would not be gained by inclining them outwards—say 6 or 9 inches in a height of 6 feet. The clay was well rammed against the walls. We would, however, prefer common earth to clay, as it swells less when wet. The two or three cracks in the sides are very trifling, not the sixteenth of an inch, yet we are convinced that before noticing them we lost water through them. There is nothing of the kind in either end which convinces us that a wall across the centre would be advisable. To prevent the clay outside being soaked, we have covered part of the surface near the tank with tar and gravel.

Two or three questions more. A says he cannot make a tank near his glass house and sheds. Ours is a considerable distance off, with connecting-pipes between them. B fears that if exposed the cement would be thrown off by frost. Such tanks would be best covered in winter by placing poles across, and laying thatched hurdles over them, with more litter in severe frost. Ours was protected for two years. Since then we lay long straw round the sides, hanging 2 or 3 feet over the water, and poles placed over the straw to keep it in its place, and the tank has not been injured by frost at all. If the frost was very hard, we would cut and remove a part of the ice in the middle, and that would save opening the ice-house. However, covering would be the safest. C would prefer a tank to be arched over out of sight altogether. To this we say that the expense will be much more, and for gardening purposes the water will be far inferior to that standing in an open tank. For years the water in a covered tank will be hard, from the cement, but that may be remedied with a little lime or soda. For domestic purposes the covered tank would be best, and should be supplied with filters, as all extraneous matter is then excluded. We have another nice tank 20 feet long, 9 wide, and 5½ deep, which we are afraid to empty out, and several rough receptacles besides, to receive the water from walks, roads, &c., and we begin to think we must have still more contrivances if we wish to be safe and keep crops going on as they should do.

Put out some Lettuces on north slopes to keep them cool, and scattered short grass that had been heated in a heap between the rows. Shaded Turnips with laurel branches to keep them a little moist. Scattered short grass over rows of Peas lately sown and well watered, to keep the moisture in. Removed the last of Broccoli, and moved part of covering off Vine-border for ground to be dug for the last general sowing of Peas. Watered Peas bearing and in full bloom, and placed short grass and litter along the rows to keep the moisture in. Littered in a similar way quarters of Cauliflower, and if we cannot water more will strew a little clean straw or hay over the heads to prevent the leaves getting slaty-coloured by an excess of evaporation. Sowed more Turnips and Radishes, the first 2 feet apart in rows and the Radishes between, and covered with wattled hurdles to keep off the full force of the sun. These, to be crisp and nice, should be sown often, the one crop put in as soon as the other appears above ground, and sowing only little pieces at a time. The White Dutch transplanted is tubering very well. We never tried it much before, though long conversant with the fact that the Swede does first-rate transplanted. Planted out Cauliflowers that had previously been pricked out, and as they were lifted with good balls will suffer little from moving, and need but little water. Pricked-out more, and sowed a little more for the autumn crop. Gave all seed-beds of Greens a watering from the cleaning-out of the tank. But for the weather many of them ought to be out. In general, notwithstanding the long drought, crops are looking well. Our last-sown Beet does not yet show, and we cannot help it by watering.

FRUIT GARDEN.

Forked the ground slightly between and around young trees of Apples, Pears, &c. Gave a potful or two of water, and then mulched with half-rotten leaves, which will keep in moisture and entice the roots to the surface. The scuffing of the surface

of the ground had kept the soil moderately moist beneath among Strawberry-rows, but still they seemed as a stand-still, looking woe-begone and refusing to swell kindly, so managed to give them a watering along the rows after strewing the ground slightly with soot and lime. Covered up immediately close to the plants with long litter, well shaken to get out most or all of the droppings; and, if the dry weather continue, will cover that again with a sprinkling of short grass that has been heated dry in a heap. This, from making the covering closer, will still farther prevent evaporation. We used at one time to use short grass from the lawn for thus protecting Strawberries and keeping them clean; but, among other objections, there was almost the certainty of getting afterwards, all over the ground, a green sward of Daisies. By throwing all such material in a heap, it will heat and ferment so violently as to kill all the seeds, and it then may be shaken out and used for this purpose, or mulching any growing crops, as Cauliflowers, Peas, Beans, &c., and every shoveller will wash some nitrogenous matter into the soil. A clergyman, who seems to be at home in gardening, told us the other day that the very best thing he ever found for mulching and keeping the fruit of Strawberries clean was rough fresh tan from the tanyard; and a moderate layer being used, very little moisture would evaporate from it after the surface was dry. In answer to our inquiry, he stated he never perceived the least taint in the fruit from the fresh tan. Very likely, just as in the case of our litter, it would generally be washed several times before the fruit was ripe. We should like those near tanyards to give the plan a trial, and report the result.

Gathered lots of Gooseberries for bottling, as they much needed thinning owing to our having pruned little last season. Observe fly clustering on the points of some of the young shoots, and sent a lad to nip the points off, and then burn them; and will syringe or engine with clear soot water to keep them at a distance, as when such fly gets a-head the berry is scarcely presentable. Tied-up canes of Raspberries that had been blown down by the wind, and thinned the young shoots. Stopped the points of the stronger shoots of Pears, Plums, and Apples, especially dwarf standards, and cut back very strong shoots to a few buds from their base, or removed them altogether where wood of moderate growth was not wanted. To keep trees dwarf and full of bloom-buds young shoots should be pinched when from 6 to 9 inches in length. This will swell but not start the buds near the base, and many of these will be bloom-buds next season. Looked over a few Plum trees that were a picture in spring, and which the birds in a few hours left a wreck, scattering the ground with flower-buds, and wood-buds too, so that the shoots are thin, and many of them stronger than they ought to be; stopped the latter early to get serviceable twigs of moderate growth. Very few bloom-buds escaped the onslaught, so we must set this against the clearing of caterpillars from the Gooseberry bushes. We hope the caterpillar will not come a second time. The extreme dryness is causing Black Currants to be slightly affected with honeydew, and we must syringe, as we cannot water. This Currant is extremely fond of moisture, provided the moisture is not stagnant, and much the same may be said of the Raspberry. The best fruit we ever saw were wild ones on the shelving banks of a running stream with the shade of deciduous trees not over-thick above them.

Watered the trees, and moistened the borders in orchard-houses to keep them cool and comfortable. Went over Cherries against walls again, the points of the shoots getting black fly on them again, though they had been dipped in tobacco and size water. We never found any plan of dipping or washing of much use unless adopted in time, as what is strong enough to kill the insects is generally sufficient to kill or blanch the leaves. Many of these leaves and young points may be pulled off at once and burned, and save much bother; and for insect-destruction, after all there is nothing like nimble fingers catching them and squeezing them, and shortly afterwards getting rid of the debris from such destruction by a good syringing with warm water. Such water at times may be used safely at 120°, but not too often, and must be used when cloudy or in the evening. Plums received much the same treatment. Those in pots and well shortened-in the previous season are some of them better supplied with fruit than wood-buds. Went over Apricots, thinning wood, nipping the points of moderate-sized shoots, and shortening back to a few buds very strong ones when they appeared. Fruit thin as a whole, owing to the wood being imperfectly ripened last season. A great object in such circumstances is to secure moderate-sized wood, and to keep it and spurs

as close to the wall as possible. Next to ripe wood and buds, dryness and sun and heat when the trees are in bloom, with plenty of air, are the chief essentials for a crop. The best and most regular crops we ever saw were on the gable ends of houses facing south, south-east, and west, with a fireplace and chimney on the other side of the wall. In cold seasons it was easy to see to what beneficial width the warmth of the chimney extended. For Apricots, therefore, if building, we should like a hollow wall heated with pipes or flues, and no other protection given except in severe weather. A very ingenious friend has just been telling us—nay, showing us—how a twelve-inch hollow brick wall can be built with three per cent. more bricks than a solid nine-inch wall, and every brick be tied and held firmly in its place, which is not the case with the common nine-inch hollow wall.

Moved the whole of the Strawberries out of the houses (vineries and Peach-houses) to cold pits, where they could get more light and air, as in shade they were getting soft and rather flavourless in the houses. The houses will now have some room in them, and not before it was wanted. The fruit, swelling and ripe, will keep much longer in such pits with plenty of air, and will keep us going until we get them ripe from the front of an orchard-house. Thinned grapes, tied-up shoots, and gave a good heat to the late house now in bloom, in addition to drawing a dry hand over the Muscats every day. Other vineries will average from 55° to 60° at night, and in these bright days will range with air given early from 80° to 90° during the day. The late house has rather less air and more artificial heat, ranging from 70° to 85° and more during the day, and averaging 65° to 70° at night, or a few degrees more, until the fruit is set, when we will let the temperature decline at night. The 70° and 75° at night for any continuance we consider more than mere waste of material in the case of Vines in general. High temperature in sunlight is a very different thing.

Regulated Melons setting, and those swelling and ripening were placed on inverted pans or saucers. They had been placed on the top of pots, but were changed to saucers or slates, as we always think that a Melon, like a bunch of Grapes, is best when the foliage protects the fruit from the full force of the sun. Some Cherries in pots have come in useful, and neither they nor those on short standards out of doors have been troubled with fly, like those on walls out of doors. Watered Fig-house; a very heavy, too heavy, crop now swelling fast and ripening; and removed the covering of leaves, and the tar and sawdust jacket from the Vine-border. A few places exposed were very dry, but all under the jacket was just nicely moist. However hot the jacket no moisture would rise from it, and the heat of the sun acting on the hard smooth surface, would bring moisture to the roots from long distances. Once we let a jacket of concrete and tar remain on a border for four years, and only removed it when we found the Vines getting far too fruitful, giving more bunches than fair-sized leaves. If we have cold evenings, will cover the border with litter. It is just moved on the surface to take a little warm rain if it come.

Attended to plants in conservatory, and those planted in flower garden, but have delayed finishing bedding plants, Dahlias, &c., as they are so much easier watered in groups close together, than if planted out.—R. F.

TO CORRESPONDENTS.

* * * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

FLORA OF THE NILE (*Mary*).—We are not aware of any special work upon this subject. It is probable there will be some information on the subject in the account Capt. Speke and Grant will publish of their discovery of the source of that river. Mr. Wyld, Charing Cross, has published a map showing their track as well as those of Rebmann, Livingstone, Andreen, Moffatt, Burton, Du Chailu, and others.

WOOLLY-ICE IN TANNERS' BARK (W. M.).—The woolly-ice like old tan. If you could move the tan you would get rid of a good many. If that cannot be done you must destroy them thus—water the bed over except about 6 inches or so at the sides; they like dryness, and will congregate there; to encourage them more, place some dry hay along the sides. Get some boiling water ready in the morning, move the hay, and as you do so pour the boiling water on the myriads you will see. Turn the tan so as to present a dry surface, place more dry hay, and repeat the process, and go on and you will beat and annihilate the enemy if you have patience and perseverance.

PEAR LEAVES BROWN-SPOTTED (E. Steaine).—We think the spotted Pear tree in your orchard-house is suffering from fructive root-action and the extra force of the sun in this hot weather. Prune off the worst leaves; disengage the foliage, shade, and dig about the roots with a spade all night. You have the fat scale on the Orange trees. You must wash off with a sponge and soap and water, and syringe with clear water in a day or two afterwards. We are obliged for information about flies. Our own opinion is that if formed of pipes, such as flues never before less than 10 or 12 inches in diameter. Small pipes of 4 and 6 inches for such purposes are great nuisances. With bricks near the furnace, and a brick rest like a cesspool at the corners, any single house not requiring a high temperature may be economically heated by such pipe-flues, and with these rests covered by tiles the dust may never be moved.

VINS LEAVES WARTED (S. W.).—The brown marks or warts are the effects of high feeding and keeping the house in the temperature you speak of—70° to 80°, with moisture in proportion. Loosen the surface of the border, give more air, and let the house fall to at least 60° at night, and from 70° to 80° with sun heat; if it is a few degrees less the vines will do all the better; and as they are very healthy they will grow out of the warty fungus matter.

PEACHES MILDEWED (W. Nolan).—Your Peaches are far from ripening-point yet, and we fear, if the specimen sent, there will be little chance of their ripening. They seem to be taken up with mildew. On the first appearance of it on either fruit or leaves the parts should have been dusted with flowers of sulphur as a remedial measure, and the more sulphur that was used in painting walls, trellis, &c., the better. For a radical cure, however, the roots must be looked to. Two opposite causes will produce this mildew. First, a cold stagnant moisture at the roots, when the top is exposed to a warm dry air, or a very dry inactive state of the roots, when the top is exposed to the excitement of a hot moist atmosphere—in other words, the want of correlative action between the roots and the branches and leaves.

CUCUMBER-PIT HEATED BY DUNG (Patelin).—But for the expense of the chamber and the bricks there is nothing to be said against your house or pit, especially for late spring and summer work. We think that long ago Mr. Fish gave a plan of a Cucumber-house with chamber; but then there were means for letting vapour out of that chamber at will, and means also for giving dry heat at top when necessary. On the whole, then, we think your house would be improved by raising the back 18 inches, and the front 6 or 9 inches; by having several moveable doors, as 6 in the wall c, to let air into the atmosphere when desirable; and having tin pipes for top heat, such as one in front and one on top of wall c, these also furnished with evaporating-pans, and then you may dismiss your mounds of dung at each side. With your present plan of air-bricks you could not use that dung unless it was previously sweetened, as a rank steam will soon settle your plants.

DISEASED GRAPES (New Bedford).—The ulcer in the Grapes is called "the spot." The roots being grown over hot-water pipes, we fear they are too dry. Without knowing more, we can only say that this disease is usually caused by the action of the roots and of the upper growths not being accordant.

APPLES (Dr. Davies, Pershore).—We do not know the Comberton Pearmain by any other name. It is very like Scarlet Pearmain, but it is not usual for that variety to keep so long as these seem to do. The seedling from Sturmer Pippin is in good condition, and promises to be a useful late Apple. The Fern is *Cyscopia* is fragile.

DENDROBATE PAXTONI (Orchidophiles).—We would remove the shoots rooted from near the tips of the old stems, and either plant around the parent or make fresh plants of them.

LAPAGERIA NOT GROWING (Idem).—Give the Lapageria a good watering and try it a little longer, and then if it does not break it would be as well to take it up from the greenhouse-border and re-pot it until it made good growth. The want of a continued application of water is the probable cause of defective growth.

MELONS FALLING WHILE SMALL (S. E. L.).—Is there no want of bottom heat or moisture at the roots? Continue giving air freely, but try and give more water to the surface soil continues rather dry by making holes for filling with water.

PEACHES MILDEWED (Nescoe).—There is no doubt that your Peaches are mildewed, and sulphuring must be resorted to, as we have told another correspondent to-day. If the ground is dry, watering would be serviceable. Peaches are more liable than Nectarines to be thus attacked.

CHARITABLE TOMATOES MANAGEMENT (Amateur).—It is best to let it flower at the proper time, and then cut the flower off when perfect, as the plant looks better without it. As the summer advances, there will be some suckers rising from the side. Remove the distant ones, but let those in the line or adjoining it remain, and now and then thin the shoots with a knife, laying the remainder in the proper line and pegging it down there. Clipping ought to be avoided, as it is apt to kill portions of the plant and disfigure the edge.

HEAT REQUIRED FOR MELONS (Melon).—From 70° to 85° before air is given is not too much for dry heat; but there is no harm if the heat declines to 65°, or even 60°, at night, provided everything else is favourable. There need be no particular change of heat after the fruit is set; in fact, Melons will not thrive at all under extreme changes, and any omission in giving air or taking it away is often fatal. See what Mr. Fish says in "Doings of the Last Week," also Mr. Keane's "Work for the Week."

PANSY SEEDLING (Woodlands, S. X.).—If the colour has not been altered in drying the Pansy is different from any we have seen; but if when fresh the tips or spots are white (as is possible), it is similar to, if not identical with, the old Magpie.

NAMES OF PLANTS (Philanthes).—The plant in the Loek garden is *Collomia coccinea*, a hardy annual, native of Chili. (*Student*).—1, An *Allium*, no leaves sent; 2 and 3, mere scraps, and undeterminable; 4, *Asperula odorata*. (*M. A. S.*)—Your specimen is too small to judge from. It looks like a pinna of a weak frond of *Asplenium lanceolatum*, and is certainly some *Asplenium* of that affinity. (*R. A. L.*)—*Asplenium adiantum-nigrum*. (*G. S. A.*)—*Anthericum Liliago*, or St. Bruno's Lily. (*H. E. K.*)—*Ceanothus dentatus*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE BEVERLEY AND EAST RIDING OF YORKSHIRE POULTRY EXHIBITION.

THE sixth annual meeting of this popular Society was held on the 3rd instant, and proved to be most successful, the poultry exhibited being of the highest class; and the collection of Pigeons also was such as to fully maintain the high reputation of this department of the Beverley Exhibition, a feature in which, from the very commencement of this Society's efforts, its annual gatherings have always excelled.

It is not open to doubt that few poultry shows have so entirely won the confidence of the public as the one of which we are now speaking, for the Committee are both painstaking and industrious, so that the success of their meetings may be entirely attributed to the personal exertions of these gentlemen, who thus leave very little connected with the Show entirely to the care of subordinates. For reasons with which we ourselves are not perfectly acquainted, it appears, however, that a change in the general arrangements has now for the first time been attempted—viz., that of curtailing the public admission to a single afternoon—a feature, we should imagine, ill-calculated to increase the sum total of the receipts derivable from monies taken at the doors. We exceedingly regret, too, that from some misconception on the part of several competitors respecting the rule contained in the prize schedule as regards the time of admission of the poultry for competition—a regulation, by-the-by, so very plainly expressed that we can only attribute the mistake to overlooking the necessary condition altogether—many most valuable consignments of both poultry and Pigeons arrived not only long after the onerous duties of the Judges were absolutely completed, but some half dozen pens were so late in their arrivals as the day following the arbitrations, consequently after the Judges had left Beverley on their return homewards.

We can fully enter into the disappointment and annoyance of the respective owners of these birds, whose losses from this cause alone were not by any means trifling, nor can we do better than again call the particular attention of exhibitors generally to the simple fact that no point in the exhibition of poultry can be of greater importance than a thoroughly careful general review of the prize schedules, compiled by each Society for the government of the exhibition for the current year, before taking the first steps as to making any entries whatever; and it is well also to carefully put aside such rules for after-guidance and reference. The neglect of this important rule on this particular occasion no doubt threw at the least twenty prizes into other hands, besides causing cards bearing the words "Too late for competition" to abound in unseemly abundance throughout the show-room.

Beverley possesses many local attractions to visitors, its minister being one of the finest architectural buildings in the kingdom. It enjoys also another church of scarcely less high repute, together with some of the most lovely rural walks imaginable. Among the latter are "The Bushes," situate a little better than a mile from the town, covering a large space of many acres, the "bushes" being a collection of many thousands of hawthorn trees just now in full bloom. The fragrance produced by these immense masses of flowers thus mingled in pleasing contrast of both red and white "May" is scarcely conceivable except by its absolute enjoyment, and this opposition of colour happily prevents the eye from palling before so brilliant a display. In this truly lovely retreat a pair (or more) of Nightingales have this season taken up their abode to the no small delight not only of the good people of Beverley itself, but also of many visitors from a distance. The consequence is that nightly these public grounds are well filled with large numbers of individuals anxious to hear the sweet warblings of these universal favourites. Disappointment very rarely ensues; for, in spite of the hum of tongues and even the cigar-smoking at such times so generally indulged in, Philomel mounts her accustomed tree and delights her nightly audience

for hours consecutively. It is earnestly to be hoped that the general desire these truly interesting birds should still enjoy their liberty will be scrupulously complied with, being the course of all others most calculated to insure in future years a similar enjoyment, as Nightingales customarily return annually to their former breeding-place. These birds, too, are not by any means common so far north as Beverley, it being about twenty years since a pair located themselves in this neighbourhood before.

But to return more immediately to the Show of poultry. Its close connection with the Floricultural Fête adds most materially to the popularity of the whole affair. A most commodious tent—large enough, it is said, to accommodate a thousand persons to dine—is the receptacle of the flowers, whilst the closely-adjacent Assembly-rooms afford everything that could be desired for the reception of the poultry. By the kind permission of Charles Reynard, Esq., the tent was erected on the beautifully-timbered grounds connected with that gentleman's private residence, adding in no slight degree to the general attraction.

By leave of Lieut.-Col. G. H. Thompson, and the officers of the East York Militia, the band of that regiment enlivened the whole proceedings throughout the day; and as the weather happily proved all that could be wished, everything proceeded as gaily as possible, bringing the sixth meeting of this Society to a most satisfactory close.

The *Spanish* fowls were unusually good, so much so, indeed, that we unhesitatingly pronounce them the best class we have seen for a long time past. Their condition as a whole was also good, and the twelve pens entered would have formed a great attraction to any show.

The *Grey Dorkings* were also excellent, though in this class not a few pens came "too late for competition," that would, if they had been present in time, have materially altered the awards. Two pens of chickens entered in this class by the Rev. J. G. A. Baker, of Bedford, are well worthy of the remark; they are the best Dorking chickens that have been exhibited this season.

In *Cochins*, Mr. Felton, of Birmingham, obtained an easy victory in Buffs, whilst Capt. Heaton was equally a-head of all competition in Partridge-coloured ones. Some extraordinarily good White ones were also shown by Mr. Dawson, of Hopton.

The *Hamburgs*, at Beverley, in pleasing contrast to those of late shows, were one of as good features as any in the Exhibition, both Pencilled and Spangled ones being equally commendable.

In *Polish*, Mr. Dixon, of Bradford, stood quite aloof from anything approaching to competition. Still the class was a good one.

The *Game Bantams* were a nice class, though we have seen better. All the other breeds of Bantams competed together, Mr. Harvey Dutton Bayley standing foremost with a pen of Silver-laced Sebrights, little short of perfection; several other pens of Sebrights being also good. Whites and Blacks were also well shown in this mixed class.

As faithful journalists, we are reluctantly compelled to mention a case of painted legs in Pen 189, belonging to Mr. George Osgerby, of Beverley. It seems last year the same unprincipled deception was practised, and at once detected. The birds, therefore, were disqualified during the appointment of the awards at that time; but this year, by a more careful manipulation, the birds at the outset obtained a second prize; but as afterwards this attempt to obtain an award was discovered, the premium was necessarily transferred to another pen, and a card distinctly stating the cause for disqualification remained attached to Mr. Osgerby's pen during the time the Show remained on view. Although Mr. Osgerby, by this renewed attempt, shows how little exposure seems to affect his own feelings, we trust that public opinion will set in strongly against such endeavours to deprive the honest exhibitor of his due reward, and eventually call into action some more telling punishment for such misdoings.

To say the *Game* at Beverley were excellent, is simply to reveal what every poultry-fancier anticipated; Messrs. Adams, Boys, and Julian, retaining among them quite the lion's share of the Game prizes at Beverley. The condition of most of the Game fowls was perfect, and the prizes were consequently secured only with difficulty. Where all were so good, we need only say, perhaps the Brown Reds were the most deserving. We could not conclude without rendering the just meed of praise due to the Game hens that were entered at Beverley.

The *Pigeon* classes were quite equal to usual, and it would be almost invidious to say which were the best classes, for the eye, even purposely seeking it, could scarcely rest on an inferior

pen. To Pigeon-fanciers, perhaps the Carriers, Powters, Barbs, Jacobins, Nuns, Trumpeters, Owls, Turbits, and Fantails, afforded such a treat as they rarely have the opportunity of enjoying.

The show of *Canaries*, *Goldfinches*, and *Mules*, was very good, even better than heretofore, and was consequently very attractive.

GAME (Black-breasted and other Red).—First, W. Boyes, Beverley. Second, H. M. Julian, Beverley. Third, H. Adams, Beverley. Commended, H. Adams; H. M. Julian; Capt. T. Percival, Whitby.

GAME (Duckwing and other Greys).—First and Second, H. Adams. Third, H. M. Julian. Commended, F. Sales, Crowle; G. W. Langdale, Leconfield.

GAME (Any other variety).—Silver Medal and First, H. Adams. Second, W. Dawson, Selly Oak. Third, H. Merkin, Driffield. (The Silver Medal is an additional prize for the best pen in the three first Game classes.)

GAME COCK (Black-breasted and other Red).—First, H. M. Julian. Second, B. Adams. Third, W. Boyes, Beverley. Highly Commended, C. W. Brierley, Rochdale; H. Adams; Mrs. H. Adams. Commended, W. Boyes; J. Sunderland, jun., Halifax; A. B. Dyas, Maderley, Salop.

GAME COCK (Duckwing and other Greys).—First, H. Adams. Second, W. Dawson. Third, W. Scott, Hotham. Commended, J. Gibbank, South Dalton.

GAME COCK (Any other variety).—First, H. Adams. Second, J. Woodhouse, Bridlington Quay. Third, F. Boyes, Beverley.

SPANISH.—First, H. Beldon, Bradford. Second and Third, R. Teebay, Fulwood, Preston. Highly Commended, J. Dixon, Bradford. Commended, S. Cotner, Fulwell, Monkwearmouth; J. Shorthose, Newcastle; T. Birch, Cornhill, Sheffield; E. Brown, Sheffield.

DORKING.—First, E. Smith, Middleton. Second, R. M. Stark, Hull. Third, E. Barrow, North Cave. Highly Commended, D. White, Driffield. Commended, Rev. J. G. A. Baker, Old Warden, Bedford.

COCHIN-CHINA (Buff, Lemon, and Cinnamon).—First, C. Felton, Eddington. Second, E. Smith, Middleton. Third, H. Bates, Edgbaston, Birmingham. Highly Commended, C. T. Bishop, Lenton, Notts; W. Whitty and Sons, Cottingham.

COCHIN-CHINA (Any other variety).—First, Capt. H. Heaton, Lower Broughton. Second, W. Dawson, Hopton. Third, C. W. Brierley, Rochdale. Highly Commended, J. Shorthose, Newcastle; J. Bolton, Edgbaston, Birmingham.

HAMBURG (Golden-pencilled).—First, S. Smith, Northwram, Halifax. Second, H. Beldon. Third, R. Hemingway, shelf, Halifax. Commended, H. Pickles, jun., Earby, near Skipton; T. Birch, Sheffield; J. E. Powers, Biggleswade.

HAMBURG (Silver-pencilled).—First, S. Fielding, Birch, Middleton. Second and Third, H. Beldon. Commended, J. E. Powers.

HAMBURG (Golden-spangled).—First, also a Silver Medal as an additional prize for the best pen of any variety of poultry exhibited, C. W. Brierley, Rochdale. Second, J. Dixon, Bradford. Third, A. Newton, Selsden, near Leeds. Highly Commended, H. Carter, Upperthong, Holmfirth; J. Crossland, jun., Wakefield.

HAMBURG (Silver-spangled).—First and Second, H. Beldon. Third, A. Newton, Silsden. Commended, R. Teebay, Fulwood.

POLISH.—First and Second, J. Dixon. Third, H. Beldon, Bradford. Highly Commended, H. Carter, Holmfirth. Commended, W. T. Addison, Sunderland.

ANY OTHER VARIETY OF FARMYARD CROSS.—First, Messrs. H. & G. Newton, Garforth. Second, H. Beldon. Third, J. Dixon. Highly Commended, H. Adams, Beverley; Mrs. White, Thearne. Commended, Miss F. C. H. Hawke, Womersley Park; R. Teebay, Fulwood.

BANTAMS (Game).—First, J. Crossland, jun., Wakefield. Second, E. Yardley, Wisewood, Sheffield. Third, H. Adams, Beverley. Highly Commended, W. Gofton, Driffield. Commended, C. W. Brierley, Rochdale.

BANTAMS (Any other variety).—First, T. H. D. Bayley, Biggleswade, Beds. Second, H. Beldon. Third, E. Yardley, Sheffield. Highly Commended, Mrs. Foster, Molescroft. Commended, J. Crossland, jun., Wakefield.

SPANISH COCK.—First, H. A. Hudson, Onsecliffe, York. Second, H. Beldon, Bradford.

DORKING COCK.—First, R. M. Stark, Hull. Second, Mrs. Seamons, Hartwell, Bucks. Commended, — Cryer, Cottingham.

COCHIN-CHINA COCK.—First, R. H. Nicholas, Malpas. Second, R. White, Sheffield. Highly Commended, E. Smith, Middleton. Commended, H. Bates, Edgbaston.

GOLD OR SILVER-PENCILLED COCK.—First, H. Beldon, Bradford. Second, J. Dixon, Bradford. Commended, J. Bilton, Cottingham.

GOLD OR SILVER-SPANGLED COCK.—First, H. Beldon. Second, J. Dixon. Highly Commended, J. Murgatroyd, Bishop Burton.

GAME HEN (Black-breasted or other Red).—First, H. Adams, Beverley. Second, W. Boyes, Beverley. Highly Commended, J. Crossland, jun., Wakefield; H. Adams. Commended, H. M. Julian, Beverley; C. W. Brierley, Rochdale.

GAME HEN (Duckwing or other Grey).—First and Second, H. Adams, Beverley.

GAME HEN (Any other variety).—First and Second, H. Adams.

SPANISH HEN.—First, H. A. Hudson, Onsecliffe, York. Second, E. Brown, Sheffield. Highly Commended, H. Beldon, Bradford.

DORKING HEN.—First, R. M. Stark, Hull. Second, Rev. J. G. A. Baker, Old Warden Vicarage. Highly Commended, J. Dixon. Commended, Rev. J. G. A. Baker; E. Smith, Middleton.

COCHIN-CHINA HEN.—First, W. Dawson, Hopton. Second, T. H. Barker, Hovingham. Highly Commended, E. Smith, Middleton; W. Whitty and Sons, Cottingham. Commended, Messrs. H. & G. Newton, Garforth.

BANTAM COCK (Any variety).—First, E. Brown, Sheffield. Second, R. M. Stark, Hull. Highly Commended, H. Bates, Edgbaston. Commended, C. W. Brierley, Rochdale; Miss Foster, Molescroft; W. Gofton, Driffield.

DUCKS (Aylesbury).—First, Mrs. Seamons, Hartwell. Second, S. Campin, Cottingham. Commended, C. Pense, Darlington; Mrs. Seamons.

DUCKS (Rouen).—First, H. Beldon, Bradford. Second, T. H. Barker, Hovingham.

DUCKS (Any other variety).—First, J. Dixon. Second, J. R. Jessop, Hull. Highly Commended, R. M. Stark, Hull. Commended, W. Witty, Driffield.

PIGEONS.

CARRIERS.—First, G. Pasby, Hull. Second, H. Beldon, Bradford.

Third, H. Yardley, Market Hall, Birmingham. Highly Commended, J. Forth, Dewsbury. Commended, J. C. Hullock, Beverley.

POWTERS.—First, H. Yardley, Birmingham. Second, G. R. Potts, Monkwearmouth. Third, H. Beldon. Highly Commended, F. Key, Beverley. Commended, E. Brown, Sheffield; H. Yardley, Birmingham.

ALMOND TUMBLERS.—First, H. Beldon. Second, Mrs. E. Southwick, Beverley. Third, J. C. Hullock, Beverley.

TUMBLERS (Any other variety).—First, H. Beldon. Second, W. Southwick, Beverley. Third, F. Key, Beverley. Highly Commended, J. C. Hullock, Beverley. Commended, H. Yardley, Birmingham.

BARBS.—First, T. D. Walker, Hoyslake. Second, H. Yardley, Birmingham. Third, Mrs. Ellington, Woodmansey.

JACOBS.—First, F. Key, Beverley. Second, Mrs. Ellington, Woodmansey. Third, T. D. Walker, Hoyslake. Highly Commended, W. Carlton, Howden. Commended, D. Causar, Erdington.

TRUMPETERS.—First, H. Beldon, Bradford. Second, F. Key, Beverley. Third, J. W. George, Beeston Podge. Highly Commended, F. Else, Bayswater. Commended, W. Carlton, Howden; H. Yardley, Birmingham; F. Key.

OWLS.—First, F. Else. Second, H. Yardley. Third, M. E. Jobling, Newcastle. Highly Commended, H. Beldon. Commended, J. C. Hullock, Beverley.

TURBITS.—First, F. Else. Second and Third, J. R. Jessop, Hull. Commended, M. E. Jobling; H. Beldon.

FANTAILS.—First, T. C. Taylor, Middlesburgh. Second and Third, J. C. Hullock. Highly Commended, H. Beldon; J. R. Jessop; F. Key. Commended, F. Else, Bayswater.

NUNS.—First, H. Beldon. Second, F. Else. Third, F. Key.

ANY OTHER VARIETY.—First, J. Wade, Leeds. Second, H. Yardley, Birmingham. Third, T. D. Walker, Hoyslake. Highly Commended, T. D. Walker; F. Key, Beverley.

CANARIES.

BELGIAN CANARIES.—First and Second, Miss Jameson, Beverley. Highly Commended, Miss Jameson; — Tritschler, Beverley. Commended, R. Jameson, Beverley.

MARKED CANARIES.—First, W. Coates, Beverley. Second, J. Pearson, Walker Gate. Highly Commended, Mrs. J. Dales, Beverley; Mrs. Pottage, Beverley; Mrs. J. Campey, Beverley; Miss M. Campey, Beverley; Miss R. Willis, Chalk Villa; Mrs. J. Pearson, Beverley; Mrs. Hobson, Fleming Gate. Commended, M. Kemp, Beverley.

ANY OTHER VARIETY.—First, — Tritschler, Beverley. Second, Mrs. Issott, Beverley. Highly Commended, Mrs. Tritschler. Commended, Miss A. Campey, Beverley.

NEST OF YOUNG CANARIES.—First, J. Campey, Beverley. Second, T. Rippon, Beverley. Highly Commended, R. Bailey, Beverley. Commended, W. Barker, Beverley.

MULES.—First and Second, Miss J. Boulton, Beverley. Highly Commended, J. Whiddall, Beverley. Commended, W. Grainger, Beverley.

REDCAPS.—First, G. Coates, Beverley. Second, Mrs. K. Fidler, Albert Terrace. Highly Commended, T. Hasker, Beverley; Miss Jameson, Beverley; K. Dawson, Beverley; J. Procter, Beverley; W. G. Drewry, Beverley.

The Judges for Poultry were—T. H. Smith, Esq., of Skelton Grange, York, and Edward Hewitt, Esq., of Sparkbrook, near Birmingham. For Pigeons—W. W. Boulton, Esq., of Beverley, and Fergus Ferguson, Esq., of Walkington, who also distributed the premiums to the singing-birds.

PROLIFIC EAST INDIAN DUCKS.

WITH regard to these Ducks which you have already mentioned, I wish to say that when the ducklings were only one or two days old, though the mother did not really neglect them, she showed a decided preference for the company of the drake; so much so, that I thought it best to confine him, as I had only two Ducks, and one was yet sitting. I saw nothing remarkable in her treatment of them, though she did not seem the most affectionate of mothers. The other Duck hatched on May 8th; and as the first had begun to lay on the 4th, I put both the old and young together in an empty shippin, when the Duck that had hatched the last brood at once took charge of the whole—twenty-two in all—the other Duck still going with them night and day, and appearing quite comfortable, although laying every morning. She has now laid fifteen eggs, and always in the nest. In fact, I have never known either of them to drop an egg abroad.

The one that hatched on May 8th began laying on the 15th, and has laid every day since that time, and they are both at this time going with the young, and leaving an egg in the same nest every morning.

I have not allowed the drake to go with them since I took him from the first lot. I have spoken to a good many farmers and others, but have not heard of such a case happening before.

—JOHN DUTTON.

PROLIFIC SWANS.

ON the basins attached to the canal at its junction with the Avon are a pair of Swans belonging to Mr. Rogers, which have proved so prolific as to be worthy a passing record. They were hatched in 1858, and in the spring of 1859 were placed in the basins covering about two acres. In the first year they took

frequent flights in the neighbourhood, and have been seen half a mile away flying over the city at a height of at least 100 feet, as judged by the tall spire of a church. However, they never deserted their allotted water, though it is close to other basins apparently more eligible and close to the river. They are never fed artificially except when the pools are iced over. Mr. Rogers, fearing their departure now each year, pulled out some of their pinion-feathers to prevent their flight.

In the year 1860 the hen laid seven eggs, hatched six cygnets, one of which was accidentally killed. In 1861 she laid nine eggs, and hatched nine, all preserved. In 1862 she laid ten eggs, and hatched eight, all preserved. In 1863 she laid nine eggs, and hatched seven, all alive and thriving. In the four seasons she has laid thirty-five eggs, and reared thirty young.—B. J. S., Bath.

SWARMING DIFFICULTIES.

I KEPT last autumn one stock in a Neighbour's cottage-hive, very weak, and to them, therefore, I united two other stocks from hives which I wanted to take, and fed liberally during the autumn by bottle, in spring with barley-sugar; but this hive is still very weak in point of numbers, though strengthening daily.

Query 1, Have I managed them properly?

I have also a large sort of bee-house, which I made myself, and which I think from all I have read, ought to be about the best kind. It is about 8 feet long, 5 high at back, and 3½ in front, all boarded-in with quarter-inch stuff covered with felt; all the back, which stands north, opening with two folding-doors, allowing three hives to face south, one east and one west.

In this house I had last autumn a strong stock of 1861 in an old straw hive facing west, A; a very strong stock of 1862 in a bar-box next to it, but facing south, B; also a strong stock of 1862 in straw hives next to this, and with the same aspect, C. These were all fed moderately in autumn and spring.

Now for difficulties. C became very crowded about the 1st of this month, hanging out during rain, so that many were drowned. I knew that I must be away from home a good deal, and wishing to manage the bees myself instead of leaving them to servants, I drove a swarm from C into an empty hive, and shook them out directly afterwards into a new Woodbury bar-frame hive. Only about a pint remained. The weather became cold and windy, so I fed them on barley-sugar; but they never worked at all, hanging in a miserable small lump to one bar.

Query 2, Had not I much better have left them to swarm according to their own devices? This morning about ten o'clock I found that C was about to swarm; they alighted on a gooseberry bush, and within five minutes B the bar-box sent out a very large swarm, which alighted on the same bush. I hived each lot separately, and in about fifteen minutes proceeded to remove them to their positions, when on lifting the first hive I found it absolutely empty, every bee having joined the other swarm. Both lots were so large that they much more than filled an empty hive. What to do I did not know. I first shook nearly half into another hive, hoping one queen might be among them; but no; they were all back in a few minutes. Then I took the Woodbury-box with the pint of bees in, and tilted that up against the brimming hive, hoping to get a good colony there. The only result was to drive out every one of those few, and then they retired themselves. After much shaking, changing, and great vexation of spirit on my part, I have now one hive settled in new quarters, so full that I have been obliged to put on a small super. The rest, I believe, have returned to the parent hives, and I almost think C may swarm again to-morrow, as I hear a deal of piping there to-night.

Query 3, What could I have done in this unfortunate dilemma?

Query 4, Why did the bar-box B swarm? I kept the little round piece of wood off the top all the spring, setting a bell-glass over the hole, to keep them cool. For the last five weeks the crown-board has been removed, and an adapter with a bar-super, as recommended by "A DEVONSHIRE BEE-KEEPER" in your answer to my questions at page 285 of last year's volume, has been put on, and in which they had begun to work; and besides this, the back doors of my bee-house facing north are set open every fine day, winter and summer.

Query 5, In this bar-super mentioned in last query the bees had begun some comb on two bars, but they are also continuing combs upwards from below. I have removed one piece. Am I to do so with all, or how prevent it?—A. W. B.

[1. You appear to have managed the bees in Neighbour's

cottage-hive very properly. They may, probably, yet do well. Your bee-house seems a good one.

2. You had certainly much better have left your bees to their own devices; but the reason of your failure was, that the queen did not accompany the driven bees. When you next attempt an operation of this kind, take care to drive out all the bees so as to make sure of the queen; then put the depopulated hive in the place of another strong stock, which must be removed to a new position, and if altered in external appearance so much the better. The returning bees will raise a queen from the brood left in the depopulated hive, and you will have succeeded in making a strong artificial swarm.

3. We never had two swarms issue at the same time and unite together, and, therefore, have no practical experience on the point. Many bee-books give directions how to act, but we think we should follow your example and leave them together, adding a super or some other temporary enlargement to the hive.

4. We cannot tell why your bar-hive swarmed. Bees are apt in this matter to exercise some of the capriciousness attributed to their sex—

"If they will, they will you may depend on't,
If they won't, they won't, and there's an end on't,"

unless they are in a moveable comb-hive, in which case it is easy to examine every comb of the depopulated stock to ascertain that no queen is present, and cut out every royal cell. This done, return the swarm by knocking the cluster out on a table close to the front of the old hive (which may be raised a little from its floor-board to admit of more rapid ingress), and replace the super, which may probably be completed before royal cells are again constructed, even if the intention to swarm be not altogether frustrated.

5. There is little objection to bees working upwards as well as downwards in a super; but if you desire to prevent it, the cells should be scraped off as soon as formed.

We really see no reason why you should be disheartened. Honey can be had from swarms as well as from supers, and if during some seasons you find the latter too troublesome, you have only to accept the good the gods send you in the shape of swarms, the bees of which may be expelled by driving, and added to other hives in the autumn whilst their stores are appropriated by the apiarian.]

DARK LIGURIAN DRONES.

I OBSERVE a statement concerning dark Ligurian drones that appears in the Journal of the 26th ult., in reply to a correspondent "J. L.," to the effect that the purest Ligurian queens will occasionally breed dark drones, which in turn may be the fathers of a more than ordinarily handsome Ligurian progeny. This precisely tallies with my experience, which, with your permission, I will proceed to narrate for the information of "J. L."

I commenced the season of 1862 with a stock of Ligurian bees procured from "A DEVONSHIRE BEE-KEEPER," in the autumn of the previous year. The workers of this stock were handsome, well-marked, and presented that transparent appearance so characteristic of the Ligurian bee; and yet the drones were uniformly of a dark colour, and, except from their superior size, were scarcely distinguishable from the ordinary black drones. This stock thrived amazingly during the spring of last year, so that in May they completely filled the twelve bar and frame hive into which they were transferred from "A DEVONSHIRE BEE-KEEPER'S" apiary. On June 1st, 1862, I took three artificial swarms from this stock, following the directions given in the pages of THE JOURNAL OF HORTICULTURE. These stocks, with the aid of a little feeding, have survived the winter, and are now in a very thriving state. However, the distinctive characteristics evinced by them are sufficiently remarkable to be worth recording.

No. 1 has a population of which a few are pure Ligurians in appearance, others precisely resemble the ordinary black bee, whilst the majority are hybrids, being but faintly tinged with the orange-coloured bar or stripe on the back which distinguishes the Ligurian variety. I conclude that these bees are the progeny of a pure Ligurian queen with a black drone. The "cross" appears to be a very good one, for they are now busily storing honey in a large glass super placed over the hive about a fortnight ago, and are far in advance of some black hives over which I placed supers at the same time.

No. 2 has a population in all respects similar to the ordinary black bee. This apparent anomaly can be accounted for only on

the supposition that the bees which clung to the two combs taken from the parent Ligurian stock, in order to form the artificial swarm, destroyed the two queen-cells that were upon these combs and raised a queen from the worker-brood of a comb taken from a hive of black bees, and which was added to the artificial swarm in order to strengthen it. The queen of this hive, as I have ascertained by inspection, is an ordinary black one, as was also that which headed a swarm from it last autumn, and which I returned at once, only for it to issue forth again on the following day in my absence and be lost.

No. 3 has a population of remarkable purity and beauty, and which must be the progeny of a Ligurian queen with a dark drone of the parent stock. I propose taking two artificial swarms from this stock as soon as the weather is sufficiently genial to afford a fair probability of success. It thus appears that my experience is entirely in accordance with your remarks respecting the dark-coloured Ligurian drone; nor do I think that "J. L." need be under any apprehension that the beauty and purity of his Ligurian stock has been deteriorated by an admixture of black blood, because the drones of the stock do not present that golden appearance which a perusal of Hermann's book on "The Italian Alp-bee" may have led him to anticipate. —RECTOR.

OUR LETTER BOX.

DUCKS' EGGS UNFERTILE (*A Constant Reader*).—Your gardener is right, a pan of water is all that is necessary for the well-doing of Ducks, unless they are wanted to breed. In that case, they must have water 18 inches deep. The lack of it not only causes unfruitful eggs, but often ruins the drake as a stock bird. If the eggs were unfruitful, they would not be rotten, but would be what are called clear eggs—that is, such as would be laid by hens or Ducks that had been kept away from the male bird. No amount of sitting spoils them, and after six or seven weeks they will remain apparently as fresh as the day they were laid. The propensity you name is not confined to drakes reared under a hen, nor did we ever hear it ended in consumption.

MANAGEMENT OF COCHIN-CHINA CHICKENS (*A Young Beginner*).—We allow our chickens to remain under the hen, but we are careful to remove the empty shells. Assuming that all eggs are put under the hen at the same time, there will be only a few hours' difference in the coming-out of the first and the last. This will be made a greater certainty if they are submitted to the water test a couple of days before the time of sitting expires. The good eggs only will be kept, and the hen will not be divided in her attentions between the chickens and the bad eggs which she believes to be good. When the hen is off her nest, take a pail three-parts full of warm, not hot, water, and place all the eggs in it. They will, of course, swim. After a few minutes the chickens will feel the warmth, and give notice of it by kicking about. Every egg that has life in it will be in motion, and will travel about in the most grotesque manner. Ten minutes are long enough, and as a rule those that remain motionless at the expiration of that time may be rejected. This process also facilitates hatching. Your feeding on chopped eggs and scalded oatmeal and barleymeal is very good. You may add a little bread and milk, and to early chickens, in very cold or damp weather, you may give beer instead of water to drink. Cochins do not care much to perch. They will, however, use low perches. Perching is more likely to produce crooked breasts than roosting on the ground. If fowls that adopt the latter have them, it is natural to them.

FOOD FOR POULTRY FATTENING (*G. J.*).—The cheapest and most advantageous food to use for fattening every description of poultry is ground oats. These must not be confounded with oatmeal or with ordinary ground oats. The preparation of them is peculiar to our great poultry county—Sussex. The whole of the oat is ground to a fine powder; nothing of any kind is taken from it. It requires a peculiar stone, dressed in a peculiar manner, to prepare it; but, when properly ground, one bushel of the meal will more effectually fatten poultry than a bushel and a half of any other meal. Mr. Agate, of Slaughman Mills, near Crawley, deals largely in it. The greatest point in fattening poultry is to feed at daybreak.

POINTS IN SILVER-SPANGLED HAMBURGS (*Gallus*).—All chickens do not moult their tail-feathers the first year. We think if all the Hamburgs in a class had red deaf-ears the Judges would be justified in disqualifying them all. There are degrees in combs. A single comb would be as fatal as a red deaf-ear; but where other points are good a small hollow must be overlooked. No crooked or lopping comb can be tolerated, nor can a faulty or deformed pike. The lacing of the wing, although desirable, may be wanting, but the barring must be perfect. The tail should be white tipped with black; failing perfection, the nearest approach must be chosen. Mrs. Pettat shows the best Hamburg cocks we ever see. You are right as to the lacing of the wing. It is most difficult to get without smudging the tail.

CANARY HEN NOT MATING (*Xendal*).—Your bird is barren, and it is useless to keep her with cock birds any longer. There are no means of making her breed.

LONDON MARKETS.—JUNE 8.

POULTRY.

The supply gradually but slowly increases. If trade were as good as it mostly is in June, there would be hardly enough, and prices would be high. As it is, they are lower than they were at this time last year.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 72.8° and 49.9° respectively. The greatest heat, 93°, occurred on the 22nd, in 1846; and the lowest cold, 30°, on the 20th, in 1855. During the period 132 days were fine, and on 120 rain fell.

USING THE WATERING-POT.

ERHAPS there is no implement used in a garden requiring so much judgment in its employment as a watering-pot, yet it is very often put into the hands of the lowest drudge, and to him are entrusted the plants of which he knows little more than that he is set to water them, and who usually regards profusion as the test of merit, pouring as much water into a thumb-pot as he would give to the roots of a Strawberry plant in the ground. That failures often arise from this need not be wondered at, and the much-hackneyed phrase of "Death in the pot" is too often applicable to the water-pot as well as to that for which the phrase was originally designed. It is, therefore, needless to offer any apology for bringing this subject before the readers of the JOURNAL OF HORTICULTURE at a season when the need for the water-pot is usually most urgent, or, in other words, at a season when the very existence of certain productions depends on its due employment.

First of all I will take a survey of the general purposes the water-pot is put to, and the prudence or imprudence with which it is wielded. Practice, aided by a certain amount of skill called cleverness, will enable most men to accomplish all mechanical operations with more or less precision and dexterity; the operation is purely mechanical, and is often performed with unwavering certainty while the mind of the operator is, perhaps, occupied with something else. Now, simple as is the operation of pouring water out of the spout, the operator ought never to do it without well considering what he is about; for though the vital power with which plants are endowed will enable them in many cases to overcome the evil effects of an overdose of the precious fluid, a too frequent repetition of this dose brings with it disease and ultimately death.

A careless handling of the water-pot is, therefore, to be deprecated; but there are other evils as well, for some very grave errors are fallen into from the lack of proper knowledge on the part of those who perform the duty of watering, and as this class is unfortunately a numerous one, let us lay the matter before them and point out the mistakes which are made.

Having said that indiscretion in watering does more harm than carelessness, we have only to look to the effect produced. Look at a poor cottager who plants his Broccoli on ground that has been cropped with Potatoes, and which in a dry season appears completely destitute of moisture. To remedy this it is not unusual to witness the water-pot or its substitute delivering water in great excess at the place where the plants are intended to be planted; perhaps a couple of quarts or more are poured in at one place, sufficient to thoroughly wet the cloddy

dry ground to the full depth or more that the dibber has to go, and while it is newly wetted the plant is put in, and the wet soil around it is pressed and kneaded as much with the dibber as it well can be, the few fibres of the plant being in fact completely sealed up, and surrounded by a substance not unlike grafting-clay. Perhaps an additional watering is given at the same time; but if dry weather continues the wetted spot becomes drier by evaporation, and also by the adjoining ground absorbing a part of its moisture, and in drying the soil recedes from the plant, leaving an air-hole somewhat less than that made by the dibber, but quite large enough to admit air down to the extreme tips of the roots, which have had no chance to take possession of the case-hardened ground. To remedy this the cottager, or inexperienced person, gives another deluge of water—very probably cold, hard, spring water, unfit in every sense for such a purpose. This drenching is repeated until the plant either succumbs, or, if its constitution survive the ordeal and it is enabled to take a feeble hold of the ground, its doing so is attributed to the assiduous waterings it has received. That no greater delusion can exist is rendered evident by comparing the final issue with results from plants differently treated as will be shown.

By way of example I will suppose the plant so treated to have been a Broccoli or some other plant of that kind, and very likely before planting it had been drawn from a bed where it had grown amongst many others, and where, consequently, the ground was dry with the exhausting crop upon it. Assuming the plant to have been simply pulled up, most of its fibres or, at all events, the points of them will have been broken off, and the plant reduced to the condition of little better than a cutting, as the elongated underground stem is scarcely a root in the usual acceptance of the term. Now, as a cutting, what chance has it to succeed by being dropped into a dibble-hole, and placed there in the alternating mediums of dry air and cold spring water? for the shrinking and contracting of the ground when dry, and its swelling again when wet, subject the plant to these changing conditions. Such is a case in which it may truly be said that "Death is in the pot."

Let us take another view of the operation, and see what can be done to secure a contrary state of circumstances. The plan is simple enough, and in many cases is attended with much less trouble than the other, and the result is more satisfactory, one or two conditions only being necessary to insure its absolute success. It is this: Instead of making the ground wet, and planting when it is so, try the reverse plan, and plant when the soil is dry; for if the soil be crumbly there will be no need of the watering-pot until the plant is in its place, and one good watering then will usually suffice. The fine dry earth being supposed to fill in all the interstices between and around the roots, and that without the kneading, which consolidates the ground in the case first particularised into something like grafting-clay, and assuming the root of the plant to be some 6 or 8 inches deep, and the ground after it is planted to be wetted that

depth, the plant is not likely to want water for several days; in fact, it is likely not to require watering any more, as it will not absorb any until it begins to grow, and it is not likely the ground will part with all its moisture by evaporation. If, however, the adjacent part not watered be exceedingly dry, and dry hot weather still continue, the dry soil will abstract moisture from the wet, and it may require replenishing again. The second watering, however, ought to be done at a time when Nature lends some assistance that way also. Should a slight shower fall, then give a good, sound watering to everything wanting it, or a dull day may be chosen for the purpose, or in the evening or early morning it may be done with like good effect.

The above is one of the examples of good and bad watering; but there are numberless others, to which it is well to call attention. Supposing a seed-bed did not promise well during the past dry spring—and there were many which did not—it is not unusual to pour on deluges of cold spring water in bright sunshine, flattening and caking the soil on the top of the bed into a hard mass, through which the seedlings in vain try to arise, and to remedy this, repeated applications from the water-pot are made, the water each time making little channels in the smooth, or rather water-worn surface of the bed. Now, this is not as it ought to be. Bright, unclouded sunshine accompanied with a dry, parching atmosphere rarely follows immediately after heavy rain. Even the sunshine after a thunder shower differs widely from the same sun shining on a bed newly and heavily watered by hand. To give artificial watering as near a resemblance as possible to the natural, the ground watered ought to be shaded from the bright glare of sunshine, and also from the over-drying effects of a north-east wind, which extracts moisture from substances that have none to spare as fast as the sun itself.

It is, therefore, prudent on all occasions, when practicable, to shade seed-beds that have received heavy waterings in dry weather until such time as the seeds germinate, or, perhaps, a change of weather may render shading no longer necessary. Some slight and temporary shading will be all that is necessary, giving at the time the bed is watered as much water as will moisten the soil at least 3 inches deep. After that, if it be necessary to repeat watering, let the quantity given be a liberal one again.

Most seeds are fed by moisture drawn by capillary attraction, and they will germinate and live with a much less amount of surface-moisture than will suffice for small plants that are newly planted. For example, a bed of small Celery plants newly pricked out requires more constant attention in watering than any description of plants that have merely vegetated on the bed they are then occupying. The healthy and vigorous roots of an undisturbed seedling will search out its food with unerring instinct, and until it come in contact with other roots of its own or a kindred kind, against which it has to withstand a keen competition for the food it is in search of, it will flourish and do well; but mutilate this root and transport both it and the plant it supports to a place foreign to it, and unless the elements be propitious some artificial assistance from the water-pot will be needed.

The foregoing are only two of the commonest instances in which the water-pot is applied judiciously or otherwise, but there are many others. A newly-planted tree, of which the roots have been cut somewhat severely, requires water, or is supposed to do so, for I am not certain that the distress it evinces arises altogether from the want of that fluid alone. Water and the necessary juices to maintain a healthy growth are two different things. I will, however, suppose a deciduous tree to have been planted in the autumn or winter, and a very dry spring or early summer to follow; a good watering once will in most cases suffice, provided that something be done to prevent evaporation. A good mulching being the best obstacle to that, it is hardly likely to require repeating, as when the tree begins to withdraw moisture from the ground for its support, moisture will be forthcoming, and to encourage this to be put off beyond the proper time will only create a greater evil than that which it is attempted to avoid. Watering newly-planted deciduous trees need not, therefore, be carried out later than the end of June, in an ordinary way, unless in special cases, or where, as in the following instance, other causes render watering more urgent, perhaps, than any I have hitherto named.

Perhaps there is no case in which the use of the watering-pot is attended with so much real benefit as where the ground is exhausted by an overcrop. Let us take, as an example, a Peach-wall, the border of which has maintained a heavy and exhausting crop of Peas, Cauliflowers, or some such moisture-

sucking vegetable, to the great detriment of the Peach, and assuming the ground to be very dry, a good watering will be of service. In fact, we might add, that a good moistening with manure water will be highly beneficial by restoring to the ground in some measure what the vegetable crop has extracted from it, and will give the Peach and other trees a chance to restore themselves to the position they would have occupied had vegetable crops not usurped the fat of the land. In this case the watering-pot is of essential service, giving the ground a thorough watering, adding some warm water to the mixture, if pond water be not to be had, so as not to chill the ground too much; and in the case of Peach trees, I would not advise any covering of the ground, but as soon as the surface of the soil is dry enough let it be stirred so as to give the sun power to play on the loose mould, and thereby warm the ground, and not cake and harden it. Peach, and similar trees require all the warmth of our English summers to perfect their growth, which need not be prolonged late in autumn. Hardier and more common things may be treated differently, or rather they may be kept growing later in the season, and, after watering, their roots may be protected by a covering of some kind.

J. ROBSON.

(To be continued.)

CONSTRUCTING AND MANAGING A MUSHROOM-HOUSE.

IN answer to the inquiries of "AN OLD SUBSCRIBER," we would say that there is no better plan for a Mushroom-house than that given in the "Cottage Gardener's Dictionary," as adopted by the late Mr. Oldaker; and if the treatment there recommended is carried out, there can be little doubt of securing plenty of good Mushrooms. As an old subscriber we could not honestly recommend you any work on Mushroom-culture, which we considered more clear and trustworthy than the articles which have appeared in these pages; in which not only the best methods, and the best materials have been described, but also directions given how to make the most of unsuitable materials when the best cannot be had. As there are several inquiries on the subject, and these chiefly relating more to our own particular practice than to general details, it may not be out of place to throw a few particulars together on this subject, and many of our friends seem to have come to the conclusion that there can scarcely be highly refined cookery without the assistance of Mushrooms in one shape or another.

Position of House.—The house adopted by Oldaker, and generally followed, is a lean-to house facing the north. Ours is a lean-to at the back of theinery. It was originally a close shed; and when we grew Mushrooms in it we had no means of giving extra heat, except by placing a fermenting heap of dung and leaves in the middle of the house, and giving an extra covering to the beds. By this means we could get plenty of Mushrooms from the middle of October to the middle of June. After that time in summer we could scarcely keep the place cool enough, and the Mushrooms came thin and sometimes maggoty, as the afternoon sun beat strongly on the slated roof. This roof, owing to the steam from fermenting matter, became rotten and unsafe, and in putting on a new roof the rafters were made of well-seasoned larch; lath was tacked on the lower side for plaster, the upper side was close-boarded before receiving the slates, and the space between the boards and the plaster was stuffed tight with clean straw, alike to keep heat in and heat and cold out.

After the second smooth plastering of the roof inside, instead of being whitened, it was, when dry, brushed over with boiled oil; and this has prevented any moisture from the beds penetrating or affecting the plaster or lath. This house is 30 feet long, 10½ wide, 12 high at back, and 8 high in front, above the ground level. Four strong cross-beams go at regular intervals from the top of the front wall, and are let into the back wall. The inside of the house is sunk a foot below the outside level, and is paved with tiles at the bottom. A pathway is set off in the middle of 3½ feet, and beneath that are two three-inch pipes. A nine-inch wall separates this space from the lower beds, and spars of wood across resting on sleepers on the top of this wall, make the pathway on a level with the ground outside. We had hot water substituted for the dung, as many were deterred from going to the Mushroom-house before, on account of the dung-heap, which was necessary in cold weather.

Such a house is just the size for having three beds on each side, like Oldaker's; and there would be no difference in the

arrangements, except that we merely give air at each end at the ridge, and instead of other openings in the roof, we have several slides and openings in the front wall, and hot-water pipes under the pathway instead of flues, which pipes are heated by a small saddle-back boiler, which also heats a vinery. We have, however, been satisfied with two beds on each side, one on the ground floor, and one on each side above it, because we were sure these would give a plentiful supply; and because there would be more room for the man to work, and the trouble of carrying up the manure in baskets by a ladder would be avoided. The heating pipes, however, have less influence on the lower beds, and if our subscriber wished to have three beds on each side, the bottom beds would just be suitable for Rhubarb, Sea-kale, Turnip-tops, and blanched Endive in winter. We generally take eight or twelve successions out of these beds. Those on the ground floor are generally made about 18 inches thick, those on the shelves 12 inches at the front, and 15 inches at back. We always make the beds on the shelves first, and then the heat from the lower beds helps the upper ones.

We confess that on turning in the hot water we had formed visions of a stylish house—brick piers, or rather iron columns along the passage, with longitudinal cross girders of iron to support a bed with sides of slate or flagstone; but we were forced to be content with upright studs of oak fastened to the sill that kept up the sparred floor at bottom, and a longitudinal plate over the cross-beams already referred to. Cross oak pieces, 3 feet apart, fastened to the upright studs at one end, and entering the wall at the other, support the floor, which consists of oak rails, 2 inches thick, and 3 inches wide, with spaces left between of $1\frac{1}{2}$ inch. A board about 11 inches wide fastened to the studs forms the front of the beds, and with a little repairs every year these beds have lasted some time. One advantage of this wood-sparred bottom for the beds is, that if a little earth is scattered over the rough litter which is used for the bottom, there will frequently be a fair crop hanging down from the bottom of the bed, as well as a thick crop on the surface. We have sometimes from these openings seen clusters 8 or 9 inches long hanging down, and some ten or fifteen in a cluster; and if not noticed in time they would almost force the slips out of their places however firmly nailed. We have, therefore, been contented with a simple arrangement; but if "OLD SUBSCRIBER" wishes for a nice house, we would advise the use of stone, or slate, instead of wood. Every year in summer we clean the house out, smoke with burning sulphur and vitriol, expose freely, and then whitewash, or rather linewash all the walls. We cannot do this just yet, as one bed is still in bearing, and our first bed out of doors, in an open shed, will not be in for a week or a fortnight.

Now as to materials. We have frequently stated how many and varied are the materials used; but for the present we shall confine ourselves to what is best for such shallow beds in houses. For this purpose the droppings of horses fed on hard food, as oats and hay, are the best, mingled with about a third of the shortest litter. If a third of the mass should consist of dried nodules of sheepdung, deerdung, or even cowdung, it will be all the better. We can scarcely ever obtain more than a casing of horse-droppings; but our whole experience points to them as the best for the bulk of shallow beds for abundant and continued bearing. These materials will heat violently when thrown into a heap fresh, and many allow them to do so to get rid of the rankness; but we prefer instead, to let such materials lie rather open and thin in a shed, as the violent heating takes away much of the nourishing properties in which the Mushroom delights. The less heat, therefore, such materials have before being made into a bed, and the less the bed itself rises above 85° to 90° , the better the chance of fine Mushrooms. When the materials are thus turned about and moderately dried, it will be well to make up the bed, though thus shallow, at two or three different times, beating firm at each time, as the exclusion of air will tend to keep the materials moist enough and prevent violent heating. The material must not be dust dry, or the Mushrooms will be poor; but it should be dry rather than wet, as if too moist the spawn will run to threads and perish. When we have imagined the material too dry, a casing of moist cowdung after spawning has given consistence to the Mushrooms. When the material was too wet, as it may often be in winter, we have wrapped each piece of spawn in a handful of short dry litter, and had fine crops.

Spawning.—Keep in view that the less violent the bed heats the better for the Mushrooms. If by a stick or a thermometer

you find that the bed remains steady at from 85° to 90° , it may be spawned by inserting pieces about the size of a walnut every 8 inches all over the bed, and about an inch below its surface. Beat firmly down after spawning. If the bed rise in temperature, just move the covering off the spawn till the heat lowers again. If the bed fall lower and seem to cool, put another inch of fresh droppings over it, and that will revive it; then, after waiting a few days to see if all is right, the bed may be earthed over. Fresh rather stiff loam is the best. This should be put on about 2 inches thick, well kneaded and beaten, which will make it from $1\frac{1}{4}$ to $1\frac{1}{2}$ inch in thickness. When well beaten and levelled, water it all over slightly, and then draw a clean spade over it to give it a smooth firm surface. We also often use turf with most of the grass removed, put on the bed grass side downwards, and a sprinkling of riddled soil over all to fill and consolidate the junctions; and though it answers very well, we are not sure if it is better than using stiffish soil. This enables you to clean your bed at any time. The Mushrooms will generally come quicker with a slight sprinkling of hay over the surface of the bed to keep it warm, but in a house heated by hot water this is less necessary; and at any time, especially in winter, warm vapour from evaporating-pans on the pipes is much relished by the Mushroom.

The chief secrets for securing plentiful crops are having the materials neither wet nor dry, but rather dry; preventing them ever heating violently; spawning when at from 80° to 90° ; never allowing the bed to become warmer, though, when the spawn is running, that will raise it a few degrees; and never raising the atmospheric temperature in the house above from 55° to 60° . Thus managed the average time from spawning to gathering will be about six weeks. In a hurry we have gathered in eighteen days. When the beds were rather cool and no means taken to heat them, we have known them take from eight to twelve weeks. When you know the spawn is all right in the bed and rather dry withal, and too cool for a quick crop, bore small holes a foot apart, water with water at 100° , and cover the bed with 2 or 3 inches of litter, and this will soon bring a crop up. Over-heating, over-moisture, and over-dryness are the chief causes of failure. In one place the only Mushrooms we ever saw came up naturally in inside Vine-borders. All the Mushrooms the Mushroom-house yielded for three years would not have served some of our cooks for a week: the material was always too moist, and the spawn was overheated. In another place the materials had extreme care; the droppings were dried and heated, and knocked about until all virtue had gone out of them, were beaten hard enough, and then scarcely ever heated enough, and the drying process was completed with a roaring fire that dried the atmosphere of the house like a killogie for corn. That house, with the materials more moist, and evaporating-pans, and steaming from the flue, ought to have supplied a township.

In *gathering* it is best to twist the Mushroom out by the roots, and never to cut unless when they come in bunches of unequal size.

In *watering* much care must be exercised. In winter scarcely any will be required if the atmosphere is kept moderately moist. In spring and autumn it is best to make small holes and pour the liquid pretty freely at back and front, as there will be a tendency to crack there. If this is not done, a little litter may be thrown on the beds, and the liquid allowed to percolate freely through it. The water may average from 60° to 70° . Of manure water we think the best is that obtained from sheep or deer dung, and in a rather clear state. Any Mushrooms on the bed should not be touched with it. We never like watering overhead in-doors on the exposed Mushrooms, as it has a tendency to make the skins leathery. In summer we were obliged to syringe walls and floor to keep the place cool, but we now prefer at such times a cellar, an open shady shed, or beds out of doors under the thick shade of trees. For winter, &c.—say from October to June, nothing is equal to a house facing the north, heated by flue or hot water. Were we under the necessity of having them in such a house all the year round, and if neatness, efficiency, and ultimate economy were the chief considerations, we would have all the walls fourteen or eighteen-inch hollow work, and would have double roofs, and then we could pretty well defy the heats of summer and the colds of winter, with the assistance of hot water when needed; and instead of wood, so liable to rot and decay, we would have iron columns and iron girders and bottom supporters, and the sides and bottoms of the beds of slate some $1\frac{1}{2}$ inch thick. Such a house would last as long as one wished, and seldom need repairs.

Much of the success, too, will depend on the spawn. Some of the best makers sometimes are deceived. From one of these we once had a supply, and we wrote back that to us it was just worth its bulk of manure. Good spawn should present a whitish appearance when broken, but the individual parts or strings should not be larger than the finest down or hair. If the white lines are many of them as large as common muslin sewing-thread the spawn is too far gone. What shall we say of that which has no other appearance than that of dried manure? In late volumes will be found full details as to the making of spawn. It is of little consequence being a year or two old, or several years old, provided it is good, and has been kept dry.

For *out-door beds* there must be more material, and for the bottom of flat beds and the centre of ridge-beds we need not be so particular. For both shapes, well wrought and sweetened dung, such as would do for Melons and Cucumbers, though not so moist, will do admirably, with or without a casing of an inch of fresh droppings. No material, however, excels old linings of Cucumber and Melon-frames, where the manure has heated itself into a dryish, caky, half-decomposed state. This, well shaken and broken, and built firmly together, will make a bed into which the spawn runs greedily. The same care must be taken as to temperature at spawning time, and the necessary heat must be maintained by coverings. We never could detect much difference in the quality of Mushrooms grown in the dark and in the light, but those who like to see the beds in a house, without a candle, may have a small window or two.

We have grown Mushrooms in all sorts of places out of doors and in-doors, as in sheds, stokeholes, floors of greenhouses, vineries, &c., and in all with much the same results, if due attention were paid to temperature at spawning time. We observe that growing them in pots and boxes has been noticed. Such has been done ever since we remember, and a good old plan it is. The pots should not be less than 15 inches, and the boxes should be 14 inches deep at least, as much through, and about 3 feet long, to move easily. They just require the same treatment as to filling and spawning as a bed, but their moveability is a great advantage—for instance, suppose a score of such pots or boxes were filled, spawned, and earthed in September and October, they could be kept in a cool dry place, slightly covered, and be placed in a slight hotbed, or by the side of hot-water pipes or a flue in forcing-houses or greenhouses. They could also be placed in a slight hotbed in a shed, or under a frame at any time, where the bottom heat would not exceed 80° to 85°, and the top heat not above 55° to 60°. Years ago, when hard driven, we have moved such boxes to the side of the heating apparatus in an early vinery; and if the Mushrooms came too quick and fast, we moved the box again into a greenhouse or a close shed—in fact, either by such modes, or even by beds out-doors or in-doors, any one who has spare shed-room, or a spare stall in byre or stable, may grow Mushrooms successfully, except, perhaps, in the months of July and August, as these months we have found the worst times for Mushrooms, except under thatched sheds or in cellars.

R. FISH.

INAUGURATION OF THE LATE PRINCE CONSORT'S MEMORIAL—JUNE 10TH.

THE aspect of the day harmonised with the occasion—there were clouds and rain and sunshine struggling for the mastery, and the sunshine prevailed. So was there sorrow tempering the pleasure of raising a fitting tribute to the memory of the Prince; but the sorrow passed away as the tidings spread that the Queen had seen and approved of the tribute—that time was softening her grief; and no one who looked upon the Prince of Wales, his bride, and his brothers and sisters, as they passed gently up to the Memorial, but felt that the cloud is less dense which shadows England, as it always shadows our land when grief afflicts its ruler, if beloved.

Our pages are not for the details of ceremonies such as was that, and we must not linger over it further than to record that the whole was well planned, the minor arrangements correctly executed, from the assembly in the balcony to the uncovering of the Statue; that there were seats for 10,000 of the nearly double that number of spectators who were present; that the banners of the various nations and corporations planted along the course of procession, added gaiety and importance to the Commemoration; that the presence of the Royal Family, the nation's ministers, the representatives of all nations with which

we are in amity, and of such a mass of British people, all testified that that day was one vast tribute of the heart to departed worth.

We copy the following narrative from our contemporary, the *Times*:—

Precisely at four o'clock, with characteristic punctuality, the Royal carriages drove up to the western entrance of the International building. The rattle of arms was heard as the guards of honour of the Grenadiers saluted, the band struck up the National Anthem, and a loud cheer greeted the entrance of the august party. The Prince of Wales was in the uniform of a General officer. The Princess, radiant and smiling as usual, was dressed in a pale mauve silk, with a rich lace mantle. The Princesses Helena and Louise were similarly attired. Prince Alfred presented a manly figure in the most elegant of all uniforms—that of the Navy; and the two younger Princes, Arthur and Leopold, wore kilts of Royal Stuart tartan. The Executive branch of the Memorial Committee and a deputation of the members of the Royal Society having been presented by the Duke of Buccleuch to the Prince of Wales, the procession was immediately formed and with trumpets sounding passed halfway down the nave, and then, turning to the left and ascending the gallery stairs, filed into a large temporary balcony, gaily decorated with garlands of flowers and scarlet hangings, which overlooked the Horticultural Gardens. The Royal party took their seats in the central part of the balcony, which projected beyond the rest of the structure. The appearance of the Prince and Princess of Wales was the signal for renewed cheering from the mass of spectators gathered in the open air.

The Duke of Buccleuch, at the head of the Council of the Horticultural Society, then approached the Prince of Wales and presented an address, which like reports at railway meetings, was "taken as read." It contained congratulations to his Royal Highness on his marriage, an expression of profound grief at the loss which the Society had sustained in the death of the Prince Consort, and assurances of gratitude for the interest which Her Majesty and the others members of the Royal Family had manifested in the institution. The address then proceeded thus:—

"The selection of the site for the Memorial of the International Exhibition of 1851 within this garden is a source of gratification to the Council; we thereby have in the view of our Fellows a lasting remembrance of their late deeply lamented President, and of the efforts he made to promote the welfare of the people of this land by so happily bringing the Exhibition of 1851 to a triumphant close. In the gracious reply which His Royal Highness made to the address which we had the honour to present to him on the 5th June, 1861, His Royal Highness advised and directed the Council to the course which should be followed to bring the undertaking to a successful issue. The principles he then laid down we have carefully treasured up and are endeavouring to carry out. Speaking of the union of the fine arts with that science which it is more especially our province to promote, His Royal Highness said:—'That which last year was still a vague conception is to day a reality, and I trust will be accepted as a valuable attempt, at least, to reunite the science and art of gardening to the sister arts of architecture, sculpture, and painting. This union existed in the best periods of art, when the same feeling pervaded and the same principles regulated them all; and if the misuse and misapplication of these principles in later times have forced again upon us the simple study and imitation of nature, individual arts have suffered by their disjunction, and the time seems now arrived when they may once more combine, without the danger of being cramped by pedantic and arbitrary rules of taste.' The excellent collection of works of art which now decorate the conservatory and arcades, and which your Royal Highnesses have already done the Society the honour of visiting, will show that we have not been unmindful of the precepts of the Prince Consort."

The address concluded with a statement of the satisfactory progress of the Society, which now numbers 3450 Fellows, and some praise of the "beauty of the gardens" and the "success of the promenades and shows," which would, perhaps, have come with better grace from other lips.

The Prince of Wales briefly thanked the Council for their address, and stated that a reply would be forwarded to them.

The united bands of the Guards then performed Lindpainter's stirring "Procession March," after which Mr. Godwin, Honorary Secretary to the Executive Department of the Memorial Committee, stepped forward and read the following address:—

"May it please your Royal Highness,—

"In the year 1853 a meeting convened by the Lord Mayor of London, Mr. Thomas Chailis, M.P., and presided over by him, was held in the Mansion House, to consider the propriety of erecting some memorial of the Great Exhibition of 1851, in connexion with a tribute of admiration to its great founder, the Prince Consort, your Royal Highness's illustrious and lamented father. The propriety of the step was at once recognised; and it was resolved unanimously, as well by the country at large as by the meeting, that the Exhibition 'was an event of the greatest importance to the nations of the world, by enabling them to observe the relative influence of science, art, and national characteristics upon production, by furnishing the means of a valuable review of the past, and by marking a new starting-point for the future progress of productive industry and giving it an increased stimulus.' The meeting saw, too, with the wise author of the

undertaking, that its tendency had been to promote useful intercourse between all peoples, and to induce in them feelings of goodwill towards each other. Money was accordingly subscribed for the erection of a Memorial, and active steps were taken to obtain a place for the intended monument on the site of the Exhibition in Hyde Park. Artists of all countries were invited to submit drawings and models in competition, and ultimately, out of nearly fifty, the design sent in by Mr. Joseph Durham was selected. The endeavours to procure a site in the Park having failed, we, the Executive Committee,—who had met with difficulties that might not have been anticipated—sought the aid of the Prince Consort. This was at once freely accorded on the condition, characteristic of his Royal Highness's noble self-denial, that the Memorial should be in no way personal, but one to which he could himself subscribe. The Royal Horticultural Society granted the fine site before which we now stand, on land belonging to the Royal Commissioners for the Great Exhibition, and therefore appropriate, the Commissioners themselves concurring in the grant; and from that time till the very last his Royal Highness continued to give consideration and personal assistance of inestimable value in completing and carrying out the project. Guided by his cultivated judgment, and aided by an increase of the funds, the design was enlarged and improved to its present form; and the last public act of the Prince in London was the approval of the statue of Her Most Gracious Majesty the Queen, then intended to surmount the Memorial. A letter from your Royal Highness after the painful event that had plunged the nation into grief conveying the will of the Queen that instead of Her Majesty's statue that of her beloved husband should crown the Memorial, and offering on your Royal Highness's own part to present the statue proposed to be thus placed—a letter which touched the heart of the country—enabled us to carry out the original desire of the subscribers, which was emphatically to offer a public and lasting tribute in connection with the Great Exhibition of 1851 to the good Prince—"to whose far-seeing and comprehensive philanthropy" (as now recorded on the face of the Memorial) "its first conception was due, and to whose clear judgment and untiring exertions in directing its execution the world is indebted for its unprecedented success." We take the liberty of expressing our great satisfaction with the admirable manner in which Mr. Durham has executed the commission confided to him. He has produced a work that we believe to be honourable alike to himself and to the country; and we trust this feeling will be generally shared in, especially by those eminent persons who assisted in the Great Exhibition, and whose names he has consequently recorded on enduring granite. In concluding this brief account of our proceedings, we tender most grateful thanks to the Queen for the interest Her Majesty has been pleased to show in the progress of this work, and the all-important assistance thus rendered us in our self-imposed labour. And we pray heartily and devoutly that Almighty God, in His goodness, long preserve Her Majesty's life—a life most precious to her loyal and loving people. It only remains for us to acknowledge most respectfully the anxious readiness with which you, Sir, accompanied by the illustrious Princess whom all the kingdom welcomes with open heart, and by your Royal brothers and sisters, have graciously taken part in the proceedings of to-day. We offer in the name of the subscribers our earnest thanks, and we solicit that your Royal Highness will now be pleased to command the uncovering of the Memorial."

To this address, the reading of which was interrupted by repeated applause, the Prince of Wales returned the following answer:—

"Gentlemen,—I have listened with an interest, which I am sure will be shared by all present, to the details which you have given in connection with the Memorial to my lamented and revered father, which we are assembled this day to inaugurate. As a son I cannot but be deeply affected by that part of your address in which you have referred to the beloved parent whose aid and counsel were never wanting when work was to be done, or when difficulties were to be overcome. (Cheers.) I am confident that our proceedings in commemorating so proud a year in England's annals would have met with his approval, and I am sustained in the part which in obedience to the Queen's commands I have undertaken, by the conviction and grateful sense that the sympathy of the entire nation accompanies me. I have now the pleasure of directing that the Memorial—of which the artist may well be proud—be now uncovered." (Cheers.)

The last words his Royal Highness concluded were scarcely audible beyond the splendid circle which were assembled round him in the balcony, but, as if intuitively, the whole assemblage turned towards the covered monument, from which neatly and quickly, as the boom of the first gun sounded, the covering was instantaneously withdrawn, showing a Memorial of which, as the Prince truly said, the artist might well be proud. It is entirely constructed of red and grey granite, as far as relates to the artist's design. The under base of Portland stone does not belong to the Memorial proper, and would have been better if in unison with the granite work, and the arches, keyed with unmeaning marks, materially detract from the composition. It is, we believe, the first public monument in which both red and grey granite, accompanied with bronze work, has been combined, at least in this country, and is in other respects new in its architectural features. The bronze statues have been produced by means of electro-deposition, which in this instance gives decided evidence of its importance in rendering the correct handling of the artist, as well as preserving the exact size of the original models, which could not be the case where the old method of casting is used.

The form of the Memorial is that of a temple, with projecting bases at four equal distances, of sufficient size to carry seated figures of 8 feet high. The entire height of the Memorial, exclusive of the under work with arches, is 42 feet; the width across the angles of the granite, 18 feet. The entablature is broken to correspond with the projections of the base. The four

seated bronze statues represent the quarters of the world in an allegorical manner, but divested of the old conventional type.

Beneath, and in front of each statue, there is a bronze medallion inserted in the granite base, the four medallions being enlarged copies from the prize medals awarded to successful exhibitors of 1851. Behind each of these statues arise two pilasters and two pillars of the Corinthian order, from stylobates placed above the heads of the statues. The capitals and bases of the columns are of bronze, the shafts of polished red granite, the effect of which is very good as an architectural decoration. Polished red granite is also introduced with equal effect in the crescent side panels of the base, and upon the circular side panels of the body of the temple. Upon the four latter panels there are inscribed in gilded incised lettering the principal features and facts relating to the first International Exhibition, including a record of all those who were actually engaged in any responsible position connected with the management of that national event, commencing with the Royal President of the Commission, the late Prince, whose statue in bronze surmounts the Memorial. It is 10 feet high, and in the mantle and with the insignia of the Master of the Order of the Bath—the Queen as Sovereign, being head of every other illustrious Order.

The statue of the Queen, as personifying "Peace," was intended originally to have been the crowning figure, but has been exchanged for that of the Prince by express desire of Her Majesty.

The frieze of the Temple bears upon it, in gilded lettering, two inscriptions,—one from Isaiah, "Let all the nations be gathered together, and let the people be assembled." The other is from the Psalms, "I will remember the works of the Lord surely I will remember Thy wonders of old." On the north tablet is the dedication of the Memorial itself, as follows:—

Erected
By public Subscription.
Originally intended only to commemorate
The International Exhibition
Of 1851,
Now
Dedicated also to the Memory of
The great Author of that Undertaking,
The good Prince,
To whose far-seeing and comprehensive Philanthropy
Its first Conception was due;
And to whose clear Judgment and untiring Exertions
In directing its Execution
The World is indebted for
Its unprecedented Success.
ALBERT FRANCIS AUGUSTUS CHARLES EMANUEL,
The Prince Consort,
Born August 26, 1819. Died December 14, 1861.

"He was a man! take him for all in all,
We shall not look upon his like again."

JOTTINGS FROM PARIS, 1863.

L'EXPOSITION DE LA SOCIÉTÉ IMPÉRIALE ET CENTRALE D'HORTICULTURE, ETC.

VEGETABLES AND FRUITS.

THAT the French people are much greater eaters of vegetables than ourselves a glance at any of their dinner-tables will sufficiently show—of vegetables not eaten, as with us, as adjuncts to more substantial viands, but forming courses by themselves, and served up in ways unknown to the ordinary dinner-tables of English folks. Not that I by any means accord to the French any abstemiousness as regards eating. Considering what a substantial meal their *déjeuner* is, and the number of courses of which their dinners consist, I am quite inclined to think that they are as great eaters as ourselves. Of course it does not look so much to have one dish at a time placed on the table as it does to have it loaded, as it too often is with us. But after all I think even as much meat is eaten with them as with us. However, this is a digression, suggested at any rate by the subject on which I wish to say a few words—the vegetables and fruits exhibited at the Exhibition of the Imperial Society of Horticulture.

France, enjoying as she does in the southern part of the country so warm a climate, and closely connected with Algeria, has the opportunity of obtaining all vegetable productions much earlier than we have; and the great markets at Paris show how, assisted by railroads, those capacities are brought to bear on the wants and luxuries of the great Parisian public: therefore one was surprised at not seeing a larger display of vegetables at any

rate than there was at the Show. I do not know whether there was any restriction placed as to the places from whence productions might be sent, although I should think not; but from the catalogue it appeared as if all the exhibitors lived not very far from Paris.

The most remarkable vegetable was unquestionably the Asparagus, and of these some enormous heads were exhibited; but although Mons. Louis Libéaut called them "*ameliorées*," I do not think they deserved the title. The heads were quite 4 inches in diameter, perfectly blanched, except about an inch of the top, which was the only edible part of them; and as I had the opportunity of tasting them I can aver that they were insipid and poor; and it certainly seemed a parody on those giants to notice, as I did on passing at the rear of the Restaurant des Trois Frères, which is supposed to know what is "*the thing*" in cooking better than any other house in Paris, that the *garçons de cuisine* were busily engaged in scraping off a good portion of the stalk, so as to leave them of a decent size to send to table. There was an interesting exhibition by one of the Argenteuil growers of Asparagus in its different stages of growth, from seedling plants to those eight years of age, at which time it appeared to me that they considered the Asparagus to be in perfection. They had been lifted up, roots and all, from the various beds, and one was thus enabled to see the character of the soil. This appeared to be almost exclusively sand, which had been enriched with plenty of dung and copious supplies of liquid manure. On inquiring at the great central markets the price of Asparagus, I found that that from Argenteuil ranked the highest, and that in proportion to its size was its price; the largest costing about two francs the bundle of about fifty heads, while a much more eatable vegetable could be obtained at about one franc the bundle.

As the various winter substitutes "*barbe de capucine*," &c., were now past, Cabbage and Cos Lettuce were exhibited as the principal ingredients for salads. There was one collection of seventeen varieties of Cos sent by M. Meurice, and also a seedling variety of his own raising; but I did not recognise anything very desirable in any of them beyond what we have ourselves.

There came one or two collections of Artichokes and Cabbage, but nothing among them that deserved particular notice. One could not help thinking that if some of our enterprising English growers were living in the south of France they would have contrived to have had many interesting subjects at the Exhibition, for many other vegetables were to be seen at the markets, and at such shops as Chevê's in the Palais Royal—as fine Tomatoes as could be grown, French Beans, Potatoes of good quality, &c.; so that with a little more enterprise and expenditure a really interesting exhibition might have been produced. As it was, a much better display could be seen elsewhere.

If the vegetables were indifferent I cannot say much for the fruits. There is a M. Ferdinand Gloede, a correspondent of your friend Mr. Radclyffe, who has written prodigious things concerning Strawberries, and I expected when I saw his name amongst the list of contributors that one would see a wonderful collection. He had a basket containing twenty-four varieties—but what a basket! It was divided into compartments about 4 inches square, and in each of these were placed some half a dozen Strawberries, many of them—most of them, indeed, I should say—English varieties. But oh! could Mr. Smith of Twickenham, or Mr. Turner of Slough, have seen the Sir Charles Napier, Sir Harrys, Victorias, &c., they would have wondered that any one calling himself a Strawberry-grower could have sent such poor specimens of his skill. It was interesting, however, in one point of view—viz., as showing that there is a probability of the French having something better than the "*fraise de quatre saisons*," which up to this time has been the sole stay of the lovers of the Strawberry amongst them. But it will be some time before they can match Mr. Smith's British Queen, in my humble opinion the greatest triumph of Strawberry-growing to be seen anywhere.

There were two collections of fruits, one having Vines, Green Gage Plum, Cherry, and Pines in pots—this was contributed by Madame Froment (veuve), of the Route d'Orleans; and another containing bunches of Muscat of Alexandria, and Black Hamburgh or Frankenthal, but very, very far inferior to those which were exhibited at the Crystal Palace on the 23rd ult. The only things which struck me as at all remarkable were the Pines, and this not from their size, but the smallness of the pots in which they were grown. There were some very tolerable Smooth Cayennes grown in pots not more than 9 inches across and very

shallow—at least I presume they were grown in them. This seemed to me (in my ignorance, perhaps), a good plan, for the immense space occupied by Pines militates against their growth; and I remember one characteristic set forth in favour of the Hurst House Seedling was, that it bore fruit in a small state, and consequently took up less room.

On the whole, then, it will be seen that I have not formed any very exalted opinion of the productions of French horticulture. The magnificent fruit which one sees later in the year, the delicious Chasselas Musqué of Fontainebleau, and the magnificent Pears of Touraine, are due rather to the excellence of the climate than the skill of the producer. In a season when skill really tells, when the difficulties of climate have to be overcome—then it is seen how indifferently French horticulturists contend with it, or at any rate how little enterprise they throw into their gardening. The fault is not theirs. The laws of property and the habits of the people are against them; and were they the same amongst us I feel that, notwithstanding the energy of our Saxon race, we should very likely fall into the same ways that they have done; and where, but for the number of amateurs in our own country, would the skill and enterprise of our nurserymen be remunerated?—D., Deal.

STRAWBERRY FAILURES.

THE following letter from a correspondent we have put into the hands of one of our weekly contributors, and append his reply thereto. Our correspondent, "A. Z.," says:—

"I have tried in vain to procure a crop on the most accreted plans, and in many kinds of soil, moving my beds to all parts of a small garden which produces excellent vegetables, and many kinds of fruit.

"I need not trouble you with my failures during past years, but will describe my last futile attempt two seasons ago. Determining not to do things by halves, I rooted out all my old Strawberry plants, and procured runners of Keens' Seedling and British Queen from a neighbour, with whom they bore abundantly, and whose garden lies on the same light, sandy stratum, and slopes as mine, to the south. These runners I planted on the old beds, having dressed them with maiden earth, old hot-bed manure, and soot; at the same time I put in others, without any preparation, in every part of the garden. At first, the plants having been previously neglected, looked dry and withered, but by the spring they had become fine plants, and blossomed profusely, but bore no fruit.

"For two seasons, whilst giving the fairest promise, I found the large trusses of beautifully expanded blossoms, some carrying upwards of fifty heads, almost entirely barren. Now, what can I do? I am too true to the craft to give in; at the same time I know I have already tried all common and many uncommon experiments, and the plants whether grown on the richest or poorest ground, present the same result of fine foliage, and profuse but futile flowering. Do you recommend any other sorts? I would be content even with the small Alpine, but I once failed in raising it from seed. I mean to profit by your hint, and plant out a few pots I have slightly forced this spring. Some of these did not flower, may I keep those in the same pots for forcing again?

"Having detailed my failures, I should like to take this opportunity of recording my successes, and thanking Mr. Anderson, to whose kind advice I in part owe them. He may, perhaps, remember a little correspondence we held on the cultivation of plants and Vines in the same house. Acting up to his caution not to attempt too great a variety, I have confined myself to such plants (and they are among the most beautiful) as were best suited to my means, and thus by constant care and growing experience, I contrive to keep up an unfailing succession of fair and fragrant flowers, from January to December, without entrenching on the requisites of the Vines, or preventing their yearly produce of a well-balanced crop of highly-flavoured fruit."

Although it is not difficult to define the cause of the want of success in the present season, it is very much so to account for the failures of former years. On dry, sandy soils, as I understand yours to be, and in an unusually dry spring like the past one, the blooms of Strawberries either become abortive, or the plant lacks the vigour necessary to swell the incipient fruit into growth, and a poor crop is the result. Even in our own case, I believe we should have had a very slight Strawberry crop had we not watered them thoroughly about the middle of May, and

again about the 1st of June. Some rain falling about the 20th of last month, and again in June on the 6th and following days, did certainly more good than the watering; but the latter was unquestionably useful. Now, if rain has not fallen in your district, and I am told it has not favoured all places alike, and you have not assisted the plants artificially with that necessary, water, the cause of failure in the present season is at once accounted for by the dryness of the weather. To some other cause, however, must be attributed the want of success in former years.

Dry, sandy soils, though certainly not the most suitable for Strawberries, are, nevertheless, good in certain seasons. The best crop I ever remember seeing was on such a soil, the season, however, favouring growth up to the time of ripening. This was in 1847. I have been told they have never been so good since, and, I believe, had never been so good before. The plants had evidently been well grown and perfected the year before, and the spring and early summer being alike favourable, the result was good. Now, in this case, success was more due to atmospheric influences, than to the character of the soil; in fact, it might almost be said to be in spite of the latter; but such cases are exceptions, a soil of a contrary description being more generally adapted to the Strawberry, and at the same time a somewhat showery season, especially in May and June.

One feature of our correspondent's practice was also bad—that of planting a new bed on the site of the old one, unless, as he says, the dressing with maiden earth and dung was liberal indeed; but the plants elsewhere in his garden ought to have been better: therefore, something else must be looked for to account for the failure of the former year. This is the more inexplicable, as our correspondent says that he generally has good vegetables in the same garden, and that a neighbour of his has good Strawberries on a soil, and in a situation of a like kind to his own. Some unexplained cause must assuredly have given rise to the failure of Keens' Seedling. The British Queen so often fails elsewhere, that its doing so in this case is not to be wondered at. Failures in forcing Strawberries are also not uncommon, and several batches of those first subjected to that ordeal often produce only indifferent crops; but this ought not to be the case with Keens' Seedling planted in the open ground, and we can only account for it by recording the instances of failure that have occurred to our knowledge from a treatment which it is possible the plants now in question may have been subjected to, which is this.

In the general instructions given for the culture of Strawberries, that of not digging between the rows is very often disregarded; the anxiety to give the plot a tidy and neat appearance induces many growers to trim the plants and dig the ground, thinking that some dung they add will more than compensate for the injury done to the roots, and that cutting away the old leaves induces fresh ones to grow. Now, in some deep soils suitable to the Strawberry, a slight digging may do so little injury that the effects will not be observable, the roots of the plants occupying the ground below being sufficiently numerous and vigorous to support the plant in health and strength; but this may not, perhaps, be the case when the subsoil is a hungry pernickious gravel, and the roots, or, say the best of them, are near the top. To destroy these roots by digging in winter after the plant has set its flower-buds in the preceding autumn is certain to be followed by failure. A fruit tree suffers in like manner, the bloom-buds prepared well expand; but the plant, deprived of part of its food, is unable to support them either in the process of setting or swelling into maturity, and either no crop or an indifferent one is the result. Assuming, therefore, that our correspondent's want of success arises from this cause, it is easy to see how it is to be remedied.

Some other collateral cause may have had something to do with the failure likewise, not the least unlikely being that barbarous practice, but rarely followed now, of mowing off the foliage in autumn. This I hardly expect was done in his case; but assuming the soil they are grown in to be somewhat light, dry, and shallow, the digging mentioned above is quite sufficient to account for the failure.

For the future I would advise our correspondent to clean off all weeds and runners, and instead of digging to cover the ground with some short rotten dung in winter, and if rain does not fall in sufficient quantity to give the plants a good watering at the time they are in flower; give them a good watering by hand, adding a little manure water at the same time. If he has fresh beds to make, I would say, Trench the ground deeply, re-

moving a part of the subsoil if it is unfavourable to the roots of the plants, and replacing it with other mould, plant some early runners much thicker than is usually done, and let them run together in a close bed.

I have known this plan answer well for one or two seasons when the plants must be removed; its supposed, and, in fact, real advantages are, that the plants do not run so much to leaf and are more fruitful, for in light soils the Strawberry being in a great measure fed by the manurial substances accorded it, is apt to run more to leaf than it ought to do. If our correspondent has not tried this plan, I would by all means advise him to do so and report the result.

He writes too well and clearly to afford any reason for thinking he has not adopted most other modes of cultivation, but this old plan answers in some places admirably. It would certainly be more advisable to turn out the plants in pots into the open ground than retain them as they are for another year; perhaps he may have some fruit in September, or at all events he will have excellent plants for another year. I should like to hear from him again on the subject.—J. ROBSON.

THE NORTHERN COUNTIES TULIP SHOW.

THE Show this year was held in this town (Manchester), on Tuesday, May 26th, at the Mechanic's Institute, in the large room. I regret to say the number of blooms exceeded the number of visitors.

The first prize was awarded to Mr. W. Lea, for a pan of six blooms—viz., Slater's Masterpiece, Sir Joseph Paxton, Mrs. Pickerrill, Atlas, Mrs. Lea, and La Vandyke. The premier Rose prize was awarded to the Feathered Rose Mrs. Lea. The second to G. W. Hardy, Esq., with Demosthenes, Sir Joseph Paxton, Violet Amiable, Fanny, Heroine, and La Vandyke. The third, Feathered, three blooms, W. Lea, with Masterpiece, Adonis, and Heroine. The fourth, J. Morris, with Charles X., Maid of Orleans, and Aglaia. The fifth, G. W. Hardy, with Demosthenes, St. Patrick, and Aglaia. The sixth, Flamed, T. Mellor, with Sans Ives, Lord Denman, and Aglaia. The seventh, G. W. Hardy, with Sir J. Paxton, Queen Charlotte, and Vandyke. The eighth, J. Morris, with Polyphemus, Van Amburgh, and Vandyke. The premier Bizarre, to T. Mellor, with Sans Ives. Two blooms, W. Downing, with Charles X. and Sans Ives; T. Halden, with Sir J. Paxton and Willson's King; and W. Bentley, with Charles X. and Aglaia.

FEATHERED AND FLAMED CLASSES.

Feathered Bizarres.

1. Sans Ives; J. Haigh
2. Sir Joseph Paxton; G. W. Hardy
3. Duke of Devonshire; W. Lea
4. Paul Pry; J. Poulson
5. Morning Star; W. Lea
6. Masterpiece; G. W. Hardy
7. Shakespere; S. Barlow
8. Charles X.; J. Morris

Flamed Bizarres.

1. Charles X.; J. Thornbry
2. Masterpiece; W. Lea
3. Sir J. Paxton; W. Lea
4. Lord Raglan; W. Lea
5. Apples; J. Bromly
6. Unknown; J. Poulson
7. Duke of Devonshire; W. Downing
8. Surpass Cattifalque; L. Ashmore

Feathered Byblæmens.

1. Maid of Orleans; Mr. Headly
2. Violet Amiable; G. W. Hardy
3. Adonis; W. Lea
4. Surpassant; S. Barlow
5. Queen of the North; J. Thornbry
6. David; H. Steward
7. Beinfait; J. Morris
8. Baquet; W. Lea

Flamed Byblæmens.

1. Lord Denman; G. W. Hardy
2. Constant; G. W. Hardy
3. Princess Royal; H. Steward
4. Prince Albert; G. W. Hardy
5. Atlas; J. Morris
6. Queen Charlotte; W. Lea
7. Victoria Regina; G. W. Hardy
8. Norah; H. Steward

Feathered Roses.

1. Industry; W. Lea

Heroine; W. Lea

3. Mrs. Sharpe; J. Walker
4. Mrs. Lea; W. Lea
5. Count Vergines; W. Lea
6. Lady Lilford; S. Barlow
7. Sarah Headly; H. Steward
8. Lady Crewe; Brooks

Flamed Roses.

1. La Vandyke; J. Morris
2. Kate Connor; G. W. Hardy
3. Aglaia; W. Lea
4. Martin's 137; G. W. Hardy
5. Lady Catherine Gordon; G. W. Hardy
6. Camelles; W. Lea
7. Triumph Royal; J. Thornbry
8. Unknown; H. Steward

Bizarre Breeders.

1. Emperor Nicholas; W. Lea
2. Omar Pasha; W. Lea
3. Titus; L. Ashmore
4. Sir J. Paxton; S. Barlow
5. Masterpiece; S. Barlow
6. No. 5 (Barlow's); S. Barlow

Byblæmen Breeders.

1. Adonis; W. Lea
2. Sante Sophia; T. Mellor
3. Unknown; W. Lea
4. Goudet Partout; S. Barlow
5. Bridesmaid; J. Cush
6. Duke of Manchester; W. Lea

Rose Breeders.

1. Juliet; H. Steward
2. Queen of England; W. Lea
3. Mrs. Lea; W. Lea
4. Ann Hathaway; S. Barlow
5. Mabel; T. Mellor
6. Mrs. Lomax; G. W. Hardy

There was a large number of blooms which covered three tables the length of the room. The day was dull, and a large

quantity of the flowers were not well open. A few of those to which prizes were awarded were past their prime, many of the blooms were small, and it was plainly observable that the frosts and cold winds had made sad ravages with the flowers, and many cracked petals were the result.

The premier rose, Mrs. Lea, a seedling of Mr. W. Lea, is a fine thing, after the style of Lady Crewe, but better, having stouter petals. Another Rose seedling of his, named Industry, is good and does him much credit. A bloom of Slater's Kate Connor, a flamed rose, shown by G. W. Hardy, Esq., was done well.

The seedlings shown were too much like the flowers from which they were raised, and require no remarks. Upon the whole, considering the season and the locality, the Show was respectable and ought to have been better patronised.

I mention the locality above. I do not think it possible to grow and blow Tulips so well there as in the south—not but it is possible to blow them clear, but not so fine, strong, and clear as in the south. I will instance one flower, the old Polyphemus, I have never seen it bloom as in the south, it seems another strain here. Some years since a bloom was shown at a Tulip Show in the Botanical Gardens in this town, by Mr. Turner, of Slough, it was all that could be wished for. Mr. Turner told me it was in the stock when he came to the Slough Nursery.

This brings to my mind many bygone years, when I have gone over the Tulip-beds at that nursery with Mr. Charles Brown, who was a persevering and enthusiastic grower of the Tulip, and from whom I first gained the rudiments of Tulip-growing. Although I brought a great many bulbs to this town, so great have been the drawbacks I have experienced, that I have entirely given up growing any but a few early Dutch bulbs in pots for decoration.

There was one improvement upon former shows that I cannot pass over, which was the entire exclusion of dirty bottoms, at least I did not see any as in former shows, not but in some cases a stained bottom can be looked over, when we bear in mind that some of the exhibitors are poor men, mostly weavers; but to their credit they can grow a Tulip fit for competition, can make a pleasure of employing their spare time over their Tulip-beds and gardens instead of wasting it at the beer-shops—and can with pleasure join in chorus with the Poet when he sings—

“Not a tree,
A plant, a leaf, a blossom but contains
A folio volume. He may read, and read,
And read again, and still find something new,
Something to please, and something to instruct.”

—DAHL, *Manchester*.

TWENTY SELECT ANNUALS.

I AM induced by a remark made by a past correspondent in THE JOURNAL OF HORTICULTURE, to send a list, to use his own phrase, “of the best twenty annuals.” His suggestion has produced a variety of answers, as to what are good and useful in this way, though none have attempted to confine themselves to his direct inquiry, and I make the attempt rather in a spirit of inquiry.

- | | |
|-------------------------------|------------------------------------|
| 1. Calendrnia umbellata. | 11. Lupinus Cruickshankii. |
| 2. discolor. | 12. Leptosiphon densiflorus. |
| 3. Rhodanthe Manglesii. | 13. Clintonia pulchella. |
| 4. maculata. | 14. Portulaca caryophylloides. |
| 5. Martynia fragrans formosa. | 15. Globe Amaranthus. |
| 6. Schizanthus retusus. | 16. Abronia umbellata. |
| 7. Nemophila insignis. | 17. Datura ceratocaulon. |
| 8. Helichrysum macranthum. | 18. Bartonia aurea. |
| 9. compositum maximum. | 19. Dianthus giganteus Heddewigii. |
| 10. Nolana prostrata. | 20. Phlox Drummondii. |

—W. EARLEY, *Digswell*.

HARDINESS OF EURYOPS PUNCTATUS.

I THANK you for your information about my plant, Euryops punctatus; but I cannot find out anything about Euryops in any of my books of reference (Miller, Don, Sprengel, Paxton, and Cottage Gardener's Dictionary); De Candolle's book I have not.

You inquire about its proved hardiness. I believe it has only been exposed this last winter; but though on the whole this has been a mild winter, yet we have had some trying times during it. In November we had frosts so hard and continuous, that we had three days' skating; and I always find that November frosts (coming while the sap is still up), are most

destructive. Then we have had several short frosts, and one especially at the end of April; yet in none of these did the Euryops even droop its shoots, and it is now a good bush, 4 feet high and covered with flowers. At any rate I am sure it does better to keep it out of doors and to take cuttings from it, which strike very readily, and so keep up young plants.

I live between Bath and Bristol, which would be considered sheltered. No doubt I can grow many things that they could not grow in Yorkshire, yet we suffer very much from early frosts, and still more from late ones; for our plants shoot early and are then cut off.—H. N. E.

[Euryops is allied to Othonna. De Candolle thus describes this species:—Glabrous; leaves filiform, deeply punctured, often trifid, sometimes sub-pinnate, pedicel three or four times longer than the leaf; involucre scaly; achæmium downy. Found near a river in the Carras desert.]

FIXING AMMONIA BENEFICIAL.

IN the extracts you make from the Rev. C. Reynold's letter on ammoniacal liquors, published in your Journal of the 26th ult., there is one important point in which I think the writer is in error. I allude to his idea that it is equally beneficial to apply solutions of ammonia in winter, as to fix it according to Liebig, and use it when required.

It is true that cold water absorbs an enormous quantity of ammonia and gradually parts with it as the temperature is raised, and at about 70° or 80° little would remain; yet let the temperature be what it may, my conviction is great loss must occur by the evaporation with aqueous vapour, &c. I think it, therefore, far preferable to fix it; or in other words, convert it into a salt that at ordinary temperature is not volatile; and the sulphate as suggested by Liebig is the best.

The addition of gypsum (sulphate of lime) or dilute sulphuric acid will attain this object. It is necessary to be careful in purchasing gypsum, as I have known persons disappointed in having chalk and rubbish palmed upon them instead of the genuine article.

Chalk may easily be detected by its effervescing with acid; but the best plan is to purchase only of respectable vendors.—AMATEUR.

PERUVIAN BARK TREES.*

THIS is the first practical work upon the cultivation of the Peruvian bark trees which has ever been published; and although Mr. McIvor with judicious modesty says that he does “not presume to furnish a perfect guide to their management,” yet we can say confidently that any good gardener having this pamphlet in his hand—containing a full record of successful cultivation—need be at no loss as to how he should manage and propagate the species of Cinchona which furnish Peruvian bark. Site; aspect; climate; elevation; propagation by seed, layers, cuttings, and buds; formation of nurseries; cultivation; planting; species yielding different barks; and directions for transmission of plants, and their treatment when they are received, are all fully particularised and illustrated by six lithographs of some of the modes of propagation and pruning.

It is satisfactory to know that although the Neilgherry bark is from trees no more than two years old, yet it yields as much of quinine and cinchonine as do the barks from maturer trees in South America. This has been ascertained by Mr. Howard's analyses. It is also satisfactory to know that attention is roused in India to the culture of these trees as a commercial object, and that about 50,000 plants have been sold or applied for. Mr. Markham may well be gratified by this ripening result of his once-unjustly depreciated efforts.

The following is a list of the species, with particulars of their qualities, cultivated in the Neilgherry garden:—

“CINCHONAS YIELDING QUININE.

“*Cinchona succirubra*, the ‘Cascarilla colorada’ or ‘Genuine Red Bark’ of commerce. This species grows to a lofty tree, and is the most valuable known, being the richest in alkaloids, which generally amount to as much as 3 to 4 per cent., and thus ‘fair average samples are valued in the market at more than twice the

* Notes on the Propagation and Cultivation of the Medicinal Cinchonas or Peruvian Bark Trees (printed and published by order of the Government of Madras). By W. G. McIvor, Superintendent of Government Cinchona Plantations, Neilgherries. 1863.

price of *Calisaya* bark.' The present price of Red Bark varies from 2s. 6d. to 8s. 9d. per pound of dry bark. This sort is also hardy, its range of growth extending from 3000 to 8000 feet; the plant, according to Mr. Spruce, prefers open ground with 'plenty of air, light, and room, wherein to develop its proportions; the bark is thin in proportion to the diameter of the trees when growing at low elevations, and thick in proportion when growing at high elevations.' The amount of 'alkaloids' is also much affected by elevation. Mr. Spruce informs us that Señor Cordovez, who has analysed the Red Bark, collected at various altitudes, found that the greater the height at which the tree grows, the larger is the proportion of alkaloids contained in the bark.'

"*Cinchona Calisaya*, or 'Yellow Bark of Bolivia.' This species grows to the height of a large forest tree, and was long considered the most valuable of all the medicinal barks; and certainly it was so until the discovery of the Red Bark. The present price of *Calisaya*, or Yellow Bark, varies from 2s. 10d. to 7s. per pound. Of this species we have evidently two varieties very distinctly marked, even when growing under the same conditions. According to Mr. Markham and Dr. Weddell, 'the tree *Calisaya* grows on declivities and steep rugged places of the mountains 5000 to 6000 feet above the sea, in the hottest forests of Carabaya and Bolivia.' Subsequently, Mr. Markham, in writing of this species, states—'There can be no doubt that the correct method of cultivating the *Cinchonas* is planting them out in the open with plenty of light and air. They may require shade from the direct rays of the sun at first. The only really fine well-grown plant of *Cinchona Calisaya* that I saw in Carabaya was one that had been planted in a small clearing entirely exposed; those in the forest were poor straggling things in comparison.'

"*Cinchona Uritusina*, the 'Cascarilla fina,' or 'Original Lora Bark,' introduced by J. E. Howard, Esq. This species, which in the days of La Condamine was a noble and lofty forest tree, is now almost extinct, the trees of a large size having entirely disappeared from the Andes; it is rich in alkaloids, good specimens giving a total of 3.8 per cent., and in this respect it equals the *Calisaya* bark of Bolivia; it was common on the mountains of Uritusina, and grows at elevations from 6000 to 8000 feet. A general opinion prevails among the *Cascarilleros* that the bark of this species 'differs in quality according as it is exposed to the morning or evening sun.'

"*Cinchona Condaminea*, the 'Cascarilla Colorada del Ray,' or 'Cascarilla Amarilla, the 'Rusty Crown Bark' of English commerce, and of equal value to the preceding species, to which it is nearly allied, inhabiting the same localities, but perhaps growing at greater elevations. In the days of Pavon this was a slender tree of little more than 24 feet in height, and is considered to be the species that produced the bark which cured the Countess of Cinchon. At the present time, Mr. Cross informs us, 'but few trees are to be seen of these dimensions. The plants from which the bark of commerce is now taken are in general not more than 8 to 10 feet in height. When the plants are cut down three or four young shoots, or suckers, in general spring up; but this does not always happen, as some of the more industrious *Cascarilleros* frequently pull up the roots, and bark them also. The bark is taken from the smallest twigs, thus the annual growths are sometimes taken, especially if they are strong.' Mr. Cross also observes 'that the alluvial deposit in the ravines where this species is found growing, is shallow, and in many places not more than 6 inches in depth.'

"*Cinchona crespilla* (C. *crispa* Tafalla), or 'fine Crown Bark.' This species is a small shrub, and contains a smaller quantity of alkaloids than the preceding; still it brings a high price in the market, being a 'very fragrant and pretty-looking bark. It grows at great elevations (from 7000 to 10,000 feet) in a deposit of peat, and where the temperature sometimes falls to 27° Fahr.

"*Cinchona lancifolia* (from Java), or 'Pataya Bark.'—This is a valuable species, it is also hardy, and easily cultivated, inhabiting the high and cold regions of the Andes. Dr. Karsten observes that 'it descends only to a height of 2000 mètres (6170 feet) above the sea, from the cold summits of the mostly snow-capped mountains, where it sometimes reaches the upper limits of the growth of trees—that is, 3500 mètres (10,797 feet).' Mr. Howard observes that 'this species produces a bark which rivals in their rich product of quinine the barks of Bolivia, and, consequently, commands a very high price.'

"CHINCONAS YIELDING CINCHONINE.

"*Cinchona nitida*, 'Quina cans legitima,' or 'Genuine Grey

Bark.' This is a lofty tree, abounding in the higher regions of Huanuco; its predominant alkaloid is Cinchonine, and is, consequently, of less value than the preceding species, which belong to the class yielding quinine: the analysis of the bark from which our seeds were gathered gave 2.22 per cent. of alkaloids, consisting chiefly of Cinchonine; Mr. Howard has, however, found quinine in samples of the fine Grey Barks of commerce. This species grows in exposed places at elevations from 6000 to 8000 feet, and is said to delight in 'free air, cold, water, and sunshine.'

"*Cinchona*, species without name. Allied to the above, and raised from seeds gathered by Mr. Pritchett, near Huanuco. Mr. Howard is of opinion that this species may prove to be identical with *Cinchona obovata* of Pavon. It is said to be a 'good bark,' and extensively imported with the Grey Bark of commerce.

"*Cinchona micrantha*, the 'Cascarilla Provinciana,' or 'Grey Bark.' This is a lofty tree, inhabiting warm and damp forests, where it attains a great circumference; one tree frequently yielding from 200 to 250 lbs. of dry bark. The bark is generally rich in alkaloids, yielding as much as 2.70 per cent. principally consisting of cinchonine.

"*Cinchona peruviana*, the 'Cascarilla Pata de Gallinaza,' or 'finest Grey Bark.' This species attains the height of an ordinary-sized tree in the forest of Cocheros, where it is still abundant, growing at a lower elevation than *Cinchona nitida*, and yields a bark of considerable value; the bark of the trees our seeds were collected from, when analysed by Mr. Howard, yielded 3 per cent. of alkaloids, comprising chiefly cinchonidine and cinchonine. It thus ranks among the most valuable of the Grey Barks."

HEATING GARDEN STRUCTURES.

(Continued from page 416.)

A FLUE to heat a house 21 feet by 15 will consume four tons of coals on an average of years, some more, some less, for the purposes of keeping out frost and damp, which at 7s. 4d. per ton, the price we give, is £1 9s. 4d., sweeping, whitewashing, and repairing, 10s., £1 19s. 4d.; but as we have Vines as well as plants a little fire heat will not be amiss in cold weather when the fruit is setting, nor out of place when the wood is ripening: therefore, two tons more coal, equal to £2 14s. Should the house be kept at forcing temperature, at least a bushel of coals will be consumed per diem, and in severe weather nearer four than one. These matters are of small significance when compared with the amount of care and attention a flue requires, and the many misfortunes their owner and attendant are heirs to.

A house 30 feet by 18 may be heated by a flue as advantageously as one of smaller dimensions; but the fire necessary to heat it would heat the piping of three houses of its size, and thus effect a saving of two-thirds.

Three thousand feet of air are as much as can be heated with one fire to advantage, and in houses that contain more, one fire will not suffice to keep out an ordinary winter's frost.

We have a house containing 7640 cubic feet heated by two flues, and in the memorable year 1860, or winter of 1860 and 1861, it consumed one ton of coke per week on an average of fourteen weeks; and it is not exaggerating to state, that although the flues were red hot, perceivable in daylight, the house was barely frost-proof. In fact, on Christmas day at 8 A.M., when the thermometer outside registered 3° below zero, that in the house only indicated 36°, and the fires had been kept going all night like a blasting-furnace. Owing to my master's hospitality, I had my nervous system lulled, or the sight of a flame issuing from a flue 18 yards in length might have tried it severely. I was called out of bed to see a sight like this at 4 A.M., and to exchange courtesies with my worthy stoker, the policeman.

But to dismiss about flues. I have no hesitation in saying, that to heat a large space they are extremely troublesome; and I cannot see any reason for a gardener having to pass restless nights when a little contrivance and a few pounds extra would remove a great deal of anxiety, and prevent him dreaming of blown-up flues, frozen houses, and a "row" afterwards. Still, I do not say a flue will not heat a house of small size and give satisfaction. What I wish to convey is this—large houses and a number of houses can be heated more satisfactorily and economically by hot water than with flues of any kind, and that the quantity of fuel necessary to heat a flue, warming a house no matter how small, will heat piping sufficient to warm double

the quantity of space heated by the flue. Besides, where a high temperature is required a boiler is more economical than a flue.

HOT WATER.—To heat a greenhouse 21 feet by 15, it is necessary to have two four-inch pipes along both ends, and in front, if a lean-to, or all round if a span.

	£	s.	d.
Saddle or cylinder boiler, &c.	3	0	0
72 feet of four-inch pipe, best quality	3	12	0
Doors, grate bars, &c.	1	6	0
Boiler-setting, with materials	1	0	0
Chimney	0	12	6
Pipes fixing at 3d. per foot (if men come a distance something extra)	0	18	0
	£10	8	6

In the above estimate, everything is good, substantial, and calculated to last the owner's lifetime. But there are cheaper ways than this. Substitute a small Arnott-stove boiler for the saddle, use pot-pipes, cement the joints, and you will have a cheaper and a better apparatus than any kind of flue whatever, for any kind of hot-water apparatus is better than flues however well constructed.

A small Arnott-stove boiler can be had for 30s., and a yard each of four-inch iron pipe connected to flow and return, to which the pot-pipes are joined, is requisite. The cost of the whole for a house 21 feet by 15, is as follows:—

	£	s.	d.
Arnott-stove boiler	1	10	0
Doors, grate, &c.	0	16	0
Fire-bricks, common ditto, mortar and chimney, setting boiler, &c.	1	5	0
72 feet four-inch glazed pot-pipes	1	0	0
6 feet iron pipe	0	10	0
Cement for joints	0	8	0
Fixing pipes, tarred rope, &c.	0	11	0
	£6	0	0

The boiler can be inside at the option of the proprietor, and a hotbed can be formed there to strike cuttings and raise flower-seeds without the trouble of making a hotbed of dung; but the doors for the sake of cleanliness should be outside. In connecting the pipes to the boiler it is of importance to allow a rise of 1 foot from the boiler. Some do this along the pipes, gradually allowing them to rise from the boiler to the flow-box; but I prefer the rise at the boiler through a bend, and then carrying the flow as nearly level as possible—that is, only allowing a rise of a few inches so as to let the extremity be the highest point to let the air out of the pipes at the feeding-cistern, which is a somewhat novel contrivance—thus, being a bend with an additional branch, I do not see any necessity for a cistern, neither would I have one unless the boiler is large, and, consequently, requires a considerable quantity of water to provide for the waste arising from circulation and evaporation. All that is usually needed is a hole through which to pour water into the pipes (as at *a* in the engraving), and that, of course, should be at the highest point, thereby doing away with the necessity for air-pipes. The return-pipe will, of course, be raised from the boiler gradually, so that it will be of the desired height at which the pipes are to run by the first bend; and from that point allow a rise of 6 inches in every 7 yards. The flow-pipe will rest on the return-pipe until it comes to the point where the return falls to the boiler, when the latter will be carried to meet the flow at its junction with the boiler without dipping; but should it dip it is not improbable that in filling the pipes with water this will run up the return-pipe and meet the current coming down the flow at the dip, and so prevent the water from circulating owing to the air being confined there; but even should the air rise (as it may with a little pressure), to the feeding-pipe or cistern, the water will not circulate so freely as when it rises from the boiler without dipping, and not at all if air be confined at the dip or anywhere along the pipes so as to cause an empty space in the pipe. —G. A. (To be continued.)

ductive of a light and airy elegance that garden artists of greater celebrity would not do amiss to profit by. Unfortunately for good taste, gardens of this kind in general exhibit such a crowding, clumsiness, and incongruity of disposition in the several figures, as to render the *tout ensemble*, in good perspective, the very reverse of elegant, comprehensive, and dignified. Too many figures in a plan, or the separate parts of the latter too widely spread asunder, when the entirety should rather be expressive of nicety in design, can but result in deformity and dissatisfaction when displayed in practice on the ground, however well suited the same arrangement might previously have appeared on paper to the uninitiated in such matters.

The vignette exhibits in perspective the accompanying ground plan circumscribed with trellis arches about 9 or 10 feet high, formed of stout rod-iron, inserted into blocks of stone

beneath the surface of the ground; and a marble figure of "Flora" is presumed, not inappropriately, to occupy the centre of the parterre. The Pelargonium garden at Oakley, the Duke of Bedford's, is thus circumscribed with iron arches; and the airy elegance thus imparted, when entwined and festooned with hardy and summer greenhouse climbers in great variety, is not the least attractive feature of the scene. A seldom used, but most classic plant for this kind of decoration is the Grape Vine. And when in early autumn the foliage of various hardy species of Vitis assume a variety of tints, and ripe and unripe bunches of Grapes in "bacchanal profusion reel to earth," or rather depend from these arches, partly concealed by green, and red and green, and purplish foliage, the effect is extremely pleasing, reminding one of Byron's lines on Italy—

"Who love to see the sunshine every day
And Vines (not nailed to walls) from tree to tree
Festooned, much like the back scene of a play."

The only difference being that the sun, perhaps, does not shine so brightly as it does in Italy, and that our Vines, instead of being "festooned from tree to tree," are merely trained from arch to arch. In addition to the Grape Vine, Clematis, Jasmine, Roses, Virginian Creepers, Honeysuckles, and other hardy climbers, are rendered decidedly more elegant and graceful in summer time by having such half-hardy greenhouse creepers as *Maurandya*, *Lophospermum*, *Rhodochiton*, *Loasa*, *Tropeolum*, *Cobaea*, &c., planted at their base annually, and induced to loosely enwreath themselves and ramble over their more sturdy compeers.

The flower-baskets also constitute an interesting feature in connection with the Pelargonium garden at Oakley; and, since this particular kind of ornament is not in very general use, the following particulars relative to it may not be considered out of place:—The basket portion is composed of robust, closely-interwoven wickerwork, annually painted green, both for effect and for the preservation of the comparatively frail material of which it is composed. In form it is circular, and made to rest upon a substantial wooden frame or support, constructed with a view to strength as well as ornament. This ornamental stand is about 18 inches or 2 feet high, square in shape, with a circular top corresponding to the diameter of the basket bottom, and like the latter, is painted green to preserve the wood, as also to harmonise in colour with the superstructure which it upholds. The flower-basket itself is about 5 feet diameter at top, 2½ feet across at bottom, and about 3 feet in depth. The interior is necessarily furnished with a portable lining of sheet-iron next the wickerwork, perforated at bottom with numerous apertures for the escape of moisture descending through the soil, and since the basket itself is bottomless, the circular false bottom of perforated sheet-iron (though, of course, placed inside the basket), is necessarily made to rest chiefly upon the ornamental latticed frame which supports it. It is, of course, a portable contrivance *in toto*, being disposed in winter in some dry airy place for the

THE PELARGONIUM GARDEN.

FOR the preparation of the annexed plan I am indebted to my tasteful friend, M. H. Seitz, of Chatsworth. There is apparent in this garden a judicious blending of gravel and grass, pro-

sake of preservation from damp, and consequent decay, until again required for use as a summer ornament. Drainage and soil are, of course, renewed annually when re-introduced to the flower-garden; and albeit the species of ornament I have described is composed, in part at least, of frail materials; if painted over yearly and taken care of in the dead season it will last for many years.

At Oakley these flower-baskets are exclusively decorated with a miscellaneous assortment of choice hybrid and Fancy Pelargoniums, fringed with the trailing Ivy-leaved and variegated

kinds, which depend over the sides in rich profusion, producing a luxuriant and yet most elegantly unique appearance. Scarlet Pelargoniums are omitted from these baskets as being too conspicuous and glaring in colour, when thus elevated so nearly to a level with the eye of the observer: and the *coup d'œil* presented is more reposeing and softer in consequence of their omission. In planting them the plants are so thickly disposed as to confer upon these beautiful flower-stands, when in full bloom, an appearance of what in truth they are—magnificent tastefully-formed bouquets of Pelargoniums.

Plan of Pelargonium Garden at Oakley.

Reference.—The accompanying plan being uniform and pretty well balanced throughout, it will be indispensable, in order to obviate any violation of the effect as a whole, that the corresponding parts be arranged so similarly in respect of the habit, height, colour, &c., of the different varieties of Pelargoniums employed in its decoration, as to confer an expressive air of unity and harmony upon the entire disposition—the respective parts of the design being thus made to reflect, as it were, the corresponding ones. This is easy of accomplishment, provided the plan be carefully studied on paper previous to planting it; and which is assuredly well worth the pains, when it is known that any material mistake in the arrangement must inevitably prove destructive to the equipoise and harmony of the picture.

The fastigate tree and dwarf bush profiles indicated on the plan are intended to represent specimens of some strict-growing and spreading plants, as Irish Yew or evergreen Cypress for the former, and Phillyrea or Laurustinus for the latter. Doubtless, however, well-mansged examples of standard or pyramidal Pelargoniums would be equally as appropriate in these positions; and the small angular beds on grass, g, near which they are planted, might most appropriately be furnished alike with masses of the "Frogmore Improved" scarlet, zoned with some variegated Pelargoniums for effecting a suitable contrast with the grass.

The small square, c, within the circular figure, z, in the centre of the gravel parterre, a, and grass-plats, b, are consecutively the sites of the statue of Flora and flower-baskets shown in the plan. The circles, z, surrounding the basket-stands, being furnished with fragrant Pelargoniums, intermingled with Heliotropes and Mignonette; the base of Flora being planted with Pelargonium Lucia rosea, margined with the gold-leaf variegated variety: a, represents gravel walks, respectively, 8, 6, and 2½ feet in width; and b indicates the grass portion of the plan.

The dotted line extending round the circumferential border, f, shows the direction of the iron trellage arches exhibited in the plan, the border itself being filled with the most brilliant kinds of scarlet, margined on both sides with the variegated Pelargonium called "Mangles' Silver Bedding."

The small circles, e, are devoted to handsome full-grown specimens of pyramidal Pelargoniums, zoned with the old dwarf Frogmore Scarlet. The best and most select bedding varieties of the "choice" and "Fancy" hybrids, with a goodly intermixture of fragrant-leaved Pelargoniums, are apportioned to the beds, d, composing the large interior circle of the garden.—GEORGE TAYLOR, Chatsworth.—(*Garden Companion*.)

TYING MATERIAL WANTED.

HAVING on more than one occasion called the attention of the readers of THE JOURNAL OF HORTICULTURE to this subject, some apology is, perhaps, due for reverting to it again; but the class likely to answer the inquiry and furnish the article wanted, being distant travellers, are not likely to see our publication regularly, and may, consequently, have not noticed the "want"

pointed out. That a foreign article is needful will be generally admitted; for I fear our home-manufacturers with all their skill will not be able to supply us with anything cheap enough to meet the requirements of every day's business; and it certainly is no compliment to those who supply us with the article in general use, or rather to ourselves also, that we have not been

able to improve on the modes of our grandfathers. Garden mats were in their days used in the same way as now—i.e., cut up for tying purposes. Some years ago, however, another article was obtained in small quantities which for a time promised to supersede the Russian matting; but its quality seemed to deteriorate after the first batch, and it fell into disrepute—this was the Cuba bast; it was also more expensive than the usual garden mats.

Now, when we take a survey of the many substances that have found their way into this country in the last twenty years or so for the various purposes of dress, household economy, or of supplying our manufacturers, it is certainly no compliment to us that a better article than Russian matting has not been discovered for tying purposes. But assuming that the material of the mat answers its purpose tolerably well, which I do not deny, the question is, Why cannot that material be imported in a condition ready for its use, instead of being worked up into mats? What I want is bundles of the fibrous material merely tied up into something like a cable, and of any suitable length in which the material is most conveniently obtained—say from 6 to 10 feet long. By this means the trouble of weaving it into mats might be avoided, and we might thus hope to have the finest and best material selected for tying purposes; whereas at the present time we have to look over a number of mats to find one that seems likely to be a good one for the purpose.

This arrangement might easily be carried out by the merchants who import the mats giving instructions to their agents abroad to procure a few bundles of the fibre dressed a little, and selected as being good, tough, and strong. Thus to the consumer the article would be at once more handy and cheaper. I do not by this mean to assert that the inner bark of the Lime from which our mats are made is the best material in the world for the purpose we put it to, but in the absence of anything better, let us have it as good as can be had; and let our adventurous travellers in distant countries see if there is nothing amongst the vegetation of other places that will answer the purpose better. Assuredly some of the interminable creepers we are told connect the trees and shrubs of other countries together with a network of great strength and persistency might be made to do service in another place and in another way; or it might be some of the reeds or grasses, or the bark of some other tree than the Lime might be tried. Brazil furnishes materials for brooms, summer hats, floorcloths, and many other articles, and it might, no doubt, with a little further effort on the part of those who explore its natural riches, furnish an article to meet our wants also. I therefore make no apology for throwing out the hint, and whether we obtain improved bark matting from the North or a substitute for it from the Tropics, it will be equally welcome, and a boon conferred on the gardening community.—J. R.

IS AN EAST OR NORTH ASPECT BEST FOR A CONSERVATORY?

IN erecting a span-roofed conservatory adjoining a drawing-room, should it be on the north or east side of the house? Would the north side do for Camellias, Azaleas, Primulas, Cinerarias, and a few other such plants in winter, as no sun at all would reach it, and for Fuchsias, Pelargoniums, Balsams, &c., in the summer? Or would you prefer the east side for these things where they would have a little sun in winter?—J. E. H.

[We presume you have no other alternative, and in such case recommend decidedly the east side. You may bloom and keep the plants on the north side, but you will have much less success in growing them.]

WEIGHT OF FRUIT OF MUSA CAVENDISHII.

I HAVE read with interest the remarks by Mr. Robson respecting *Musa Cavendishii*. It may, perhaps, interest him to learn the weight of fruit that was cut from a plant here. The plant was brought here in a small pot by a lady, and planted the 14th of April, 1862, and the fruit was cut the last week in April, 1863, weighing 42 lbs. (14 ozs. to the pound). I may say before I cut the whole bunch my employer weighed the largest two cones, 7 ozs. each. The barren end was cut off six weeks before the fruit was ripe, and I am sorry I cannot give you the exact

number; I should suppose about 126.—M. BAYNES, *Well Head, Halifax, Yorkshire*.

[Why were only 14 ozs. allowed to the pound? Sixteen ounces being the usual allowance, a deduction of one-eighth is to be made from the above weight, which reduces it to 36 lbs. 12 ozs.]

ENTOMOLOGICAL SOCIETY'S MEETING.

A MEETING of this Society was held on May 4th; F. Smith, Esq., President, in the chair.

Mr. S. Stevens exhibited a number of insects from South Africa collected by Mr. Trimen; a collection from Madagascar sent home by Mr. Plant, containing a few Coleoptera and some fine Lepidoptera, conspicuous amongst which was a new *Dia-dema*; a collection from the Feejee Islands, principally of Coleoptera, and comprising many new species; some spiders from Bogota of enormous size; and a specimen from Australia, which was apparently undistinguishable from the British *Sinodendron cylindricum*.

Mr. M'Lachlan exhibited the case of a Caddice Worm (*Lim-nephilus*), which was entirely composed of small shells (of a *Planorbis*), from 250 to 300 in number, arranged with the utmost regularity so as to resemble a piece of mosaic.

Mr. Edwin Shepherd exhibited specimens of *Biston betularius*, which had been reared from eggs sent to him from Lancashire. Mr. Edelsten had last year found a pair of this species in copula, one being the normal form of the insect, and the other the black variety sometimes found in the north of England. The eggs sent to Mr. Shepherd were the fruit of that union; and from them twelve specimens of the perfect Moth had emerged, of which eight were of the ordinary colour, whilst four were of the negro variety. Of the twelve, ten were females; and of the two males one was a negro. The whole of the larvæ had been fed on the same food, principally on Lime leaves. It was remarkable that the black variety had never been captured in the south, and that no intermediate forms had ever been bred to connect and link together the light grey type and the sooty black variety.

Mr. Waterhouse exhibited *Oxypoda lentula* and *O. miscella*, both hitherto unrecorded as British species; also a British specimen of *Trechus*, which he considered to be identical with the insect sent to him by Dr. Schaum as *T. obtusus*; and specimens of *Philochthus Mannerheimii* taken at Darenth Wood.

Mr. Waring exhibited some dead pupæ of drones which he had found near the entrance of one of his bee-hives. They were not quite fully matured, and it would seem that the bees must have cut off the caps of the cells and cast out the dead pupæ; but he was unable to throw any light upon the cause of their death.

Mr. J. W. Wood made some remarks on the colouration and mimicry of nature visible on the under side of the wings of *Anthocharis cardamines* when at rest, and on the utility of this colouring on the preservation of the insect. The Butterfly might during the present month be found towards evening, or in cloudy weather, at rest in very exposed situations—on the tops of Grasses and flowers, and more particularly on those of *Anthriscus sylvestris*. The chequered white and green of the wings exactly resembled the small white flowers of the *Anthriscus* as seen against the green background of the hedgerow behind, and thus preserved the insect from observation. It was to be remarked, too, that, except as a secure resting-place, the Butterfly did not appear to be partial to the *Anthriscus*, but preferred to hover over and suck the juices of the wild *Geranium* and other plants.

A letter was read from Dr. Hagen, of Königsberg, the author of the recently published "*Bibliotheca Entomologica*," requesting British entomologists to communicate to this Society any errors or omissions which might be found in that work, and of additions to be made thereto, in order that by such assistance and co-operation the work might hereafter be made perfect and maintained complete.—(*Athenæum*.)

LANCASHIRE DISTRESSED WORKINGMEN BOTANISTS.—I have received from Lady D. Nevill £1 since I last wrote, on their account.—JOHN HAGUE, 36, Mount Street, Ashton-under-Lyne.

WORK FOR THE WEEK.

KITCHEN GARDEN.

ATTEND to the thinning of the crops, and keep the soil loose where it is possible to do so. *Asparagus*, now is a good time to apply salt to the beds, and also to Sea-kale-beds. About 1 lb., to a square yard is sufficient. It is a great waste to lay it on after the plants have done growing, particularly when the soil is at all inclined to be cold and stiff. Stimulants applied now will enable the roots to lay up a good store of organised matter for another season, and, therefore, in addition to salt, occasional applications of manure should be given if possible. The effect of this kind of treatment will be perceived in the autumn by the plants retaining their green colour much longer than others not so treated, and in the spring by increased size and productiveness, evidently showing that the longer the functions of the plants can be preserved by the application of stimulants, the greater amount of matter is stored up for the ensuing season. *Broccoli*, the planting-out of these and the Winter Greens, Kales, Cabbages, Cauli-flowers, &c., must be vigorously prosecuted, and every vacant space should now be kept well filled-up. Liquid manure will be in continual request. *Celery*, the trenches for the main crops should now be prepared. For this purpose the spaces between the rows of Peas are very applicable; the shade from the Peas will be very useful to the Celery in its earliest stages, and they will be entirely removed by the time they are likely to be injurious. *Dwarf Kidney Beans*, another sowing may be put in for succession, and advancing crops both of these and Scarlet Runners well thinned out. Keep the soil about them well forked-up and pulverised. Experience goes far to prove that the fork is the best implement that can be used amongst all wide open crops. *Peas*, continue to top them, and also the Broad Beans as they advance, and keep them well gathered as they become fit for table. Make another sowing of Peas. The Early Frame is a good sort for this and the next sowing, after which time there will be but little chance of their coming to perfection. *Turnips*, keep them well thinned out and watered when needful. Make successional sowings. *Tomatoes*, see that they are kept well thinned out, and nailed to the fence or walls.

FLOWER GARDEN.

The most pressing work at present is that of keeping the place in order. A little pains taken with the walks at this season will be amply repaid by the air of comfort and pleasure which well-kept walks give to any place. Cuttings of *Roses* may now be taken and planted in a close cold frame in a northern aspect. In about a month they will be callused over, indicating a disposition to strike root, when they may be taken up carefully, potted, and plunged in a slight bottom heat. Treated thus they will make nice plants in a short time, and if kept under slight protection during winter will fill their pots with roots and be ready for planting out next May. Remove suckers from *Roses*, and clear the stems of wild shoots. Strong shoots of *Chrysanthemums* may now be layered in pots to produce dwarf, compact bushes. Those in pots may soon receive their final shift, and such struck-cuttings as have been planted out in the open ground to be frequently topped until the middle of July, to make bushy plants for taking up and potting in the autumn. Cuttings put in now will also make nice plants by the autumn. Those bulbs which are placed in the borders and which add so much to the beauty and lively appearance of the flower garden and shrubbery during the spring months, should now have some attention. Those that require it should be taken up. We would not recommend this to be done annually, but only when necessity requires it. An acquaintance with the different species will direct the cultivator in his operations in this respect. Some species, for instance *Crocuses*, *Tulips*, &c., form new bulbs beside the old ones, and in course of time become so crowded as to become weak and cease to flower; others form their new bulbs under the old ones, and at last get so deep as to produce the same effect. Others, again, form their new bulbs over the old ones, and send them above the surface of the ground, where they are destroyed by the hoe, the rake, or the frost. All those that require taking up should be lifted now and housed till autumn. Decayed patches of bulbs which are required to stand for early-spring flowering, may have *Verbenas* or other things introduced from pots between them, so as to give gaiety to the places they occupy. Cuttings of *Pansies* to be put in before the shoots are too much exhausted. All boundary or other hedges to be clipped forthwith.

FRUIT GARDEN.

The nailing of the young wood of wall trees to be continually followed up. Strawberries will now require timely applications of water according to the state of the weather, and the fruit to be protected from birds. Thin-out the young canes of *Raspberries*. Pinch-out the tops of the young shoots of *Figs*, and thin the fruit if too thick. As soon as the *Grapes* on the open walls are set they should be well thinned, it amply repays the extra trouble.

GREENHOUSE AND CONSERVATORY.

Remove to houses with a north aspect or under the shade of a north wall any plants whose period of blooming it may be desirable to prolong. Seedling Chinese *Primroses*, *Cinerarias*, and other plants required to furnish the winter supply of bloom should now be forwarded by shifting into small pots; keep them in a cold frame where a slight shade can be given them in hot weather; or, what is better, turn the frame to the north. By pinching-out the blossom-buds of the young *Pelargoniums* a late bloom may be secured. The *Perpetual* and *Bourbon* *Roses* which have been forced to be placed in a cool situation with the object of repressing further activity. After a season of rest the soil to be shaken from them, and all decayed roots removed, after which to be potted in fresh rich soil, and removed to the protection of a cold pit, and there plunged. Let shading be used with caution at all times whenever the weather is in any way dull. As plants will soon be ripening their young wood, they want as much light and even moderate sunshine as possible.

STOVE.

As light has now reached the maximum point, and solar heat nearly so, fires may be dispensed with here, except, perhaps, on the evenings of wet days, when a little fire will be necessary to allow of admitting air early in the morning. Propagate *Luculia gratissima* by cuttings. *Gesnera zebrina* may still be potted for late blooming. The *Achimenes* and *Begonias* for succession to be repotted progressively. *Gardenias* and other things that have been in the conservatory while in bloom to be replaced in heat as soon as their beauty is over, in order to allow time for their growth being ripened before short days and dull weather shall have arrived. Look well about the stands of *Stanhopeas* and *Oncidiums* now about blooming, that no snails are concealed.

WINDOW FLOWERS.

A few words on this subject may be useful. When the windows and balconies are filled with a selection of plants according to taste, and these are potted into moderately large pots sufficient to last them through the growing season, they will require little other attention besides watering, which must be very regularly and constantly done. Plants in this situation, from the position they occupy, are extremely liable to suffer from drought if there is the least neglect in administering their supply of water. This applies equally to all kinds of plants cultivated in these situations. In order to protect the plants from injury in consequence of the powerful rays of the sun striking directly on the side of the pots, often very thin, and forming a mere shell around the roots, it is advantageous to set the pots containing the plants within others just large enough to contain them; the double sides of the pots, together with the small open cavity all around between the two, prevent the evil to a very great extent, and it may be still further prevented by choosing the exterior pot still larger, and filling the cavity between the two with moss, which is to be kept damped. Where moss is easily procured a bed of it may be formed on the window-ledge, in which the pots could be plunged, the moss being kept damp. W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

A GLORIOUS rain since our last, and continued warm, sunny showers, have given a fresh aspect to garden and field, and cheered the heart of the cultivator, bringing to his lips the words of out-spoken gratitude. Though planting was tempting, yet several times the men were sent to sheds, to stick-pointing, and pot-washing, as the sweet pearly drops of rain would do more good in the ground than upon their backs. When we look back to the times when it was common for men to nail with the trees covered with snow, and to mow with the water running down their limbs, and gurgling up over their shoes, we for one have no faith in the old adage, that "the former times are better than these." Few even of the disciplinarians would have the

heart to enforce such practices now, though even still it is no uncommon thing to hear of horses being brought in out of the wet, and men sent out in the rain to fare as they may. Think of poor ploughboys getting home to their stables soaked, putting on next day the clothes they had no chance of drying, and need we wonder that instead of being at their best, they become old men at thirty and thirty-five, and get crooked with pains and penalties ever afterwards? Most of us, however, would have been glad to put up with a drenching in the continued drought. We feel grateful for the attempts that are made to improve the condition of working men in their homes; but a nice cottage is but an unsuitable home, if deficient in the supply of good water. It would be well if there were something like a legal enactment as to wells or tanks, as relates to the proprietors of cottage property. We know of villages in which, if there should be a well, few have any right to use it, and for water for all sorts of purposes, cooking included, the residents must resort to pools and holes, where the water has flowed from the highway in floods, and most of which in elevated districts were completely dried-up in the late drought. It was sickening to see the poor women trying to fill a little pail, by skimming with a saucer a piece of water less than a yard square, and passing it through a cloth before it could be used for anything. Need we wonder at the prevalence of goitre, and thick necks, and numberless maladies produced by such unwholesome water? Were I a legislator, I should try to enact that the landlord, who looks sharply enough after cottage rents, should be constrained to provide by tank or well for his cottages, so that the inmates should have something else to depend upon for that essential necessary—good water, than the puddles and pools by the side of the highways, &c.

Planted-out some Brussels Sprouts, Savoy, and Scotch Kale, and must prick-out more for want of room to finally transplant. Planted also a good breadth of Cauliflower. Thinned all Onions, laying the thinnings in thickly by the heels for salads. Thinned also Parsnips and Carrots finally. Removed all the seed-heads from Sea-kale, except those wanted for seed, and thinned out the crowns. Threw a little lime and ashes over Beetroot and late Carrots. Made the last sowing of Peas and garden Beans, unless, perhaps, a row or two of early kinds of the former in the end of the month. Sowed more Lettuce. Thinned Turnips. Cut down all Parsley showing seed-stalks, except a few for seed, as this will cause the stools to produce longer, and give more time for the young Parsley. Notice that young Sea-kale and Asparagus is coming thick enough now. Ceased gathering old beds of Asparagus; in fact, as we have plenty of Peas in-doors and out of doors, have cared little about it of late. Prepared for planting Celery, the forwardest being large plants, and will hoe all ground as soon as the weather changes, to keep the moisture in the ground. Cauliflowers and other vegetables have grown amazingly since the rain. Put a little more covering on the Mushroom-bed in the shed, after the cooler weather with the rain, and made up a little bit more at the end of it for succession. Some weeks ago we mentioned tar being put on the side of a bed in the Mushroom-house. Though as much removed as possible, the smell is not yet quite gone, and as that and woodlice together threatened the young Mushrooms, we have set the tops of hand-lights firmly on the beds, and within the Mushrooms are coming nicely. As soon as the bed in the shed is bearing, we will clear out this bed, clean and smoke the house with sulphur and a little vitriol, which will pretty well destroy all woodlice that may be left. The worst of it is, that in all old gardens there is almost sure to be some taken in with the material for the beds, just as mice are taken in sheaves into barns and stacks rendered misproof. Regulated Cucumbers, planted fresh beds, and potted-off Capsicums, Chilies, &c.

FRUIT GARDEN.

Much the same as the last week, only the rain has saved us the trouble of driving honeydew and many insects from bushes, &c. Watered Figs heavily as the crop is heavy, and put a little fire on in the duller days with more air, as two or three fruit showed signs of damping at the points. Have gathered a considerable number. Some gentlemen told us that the prettiest sight we had were some Cherry trees in a cool orchard-house, covered with fruit from pot to top like a red wreath. These and others have certainly been very useful, and have given very little trouble. Some Bigarreaux and Downtons, though paler in colour, have also been fine in size and quality. We have in the same place a few young Apricot trees, but they do not please

us at all. A few Plums are just too heavily fruited. We think either on trellis or as standards, planted out or in pots, a house of such Plums as Jefferson's and Coe's Golden Drop, would in the late autumn be a great luxury. Regulated Vines, Melons, Peaches, &c., as last week.

ORNAMENTAL DEPARTMENT.

In wet days, potting was the chief employment, but the week has been so busy with planting-out in the flower garden, that we have no time to write about it. Beds were beat up and all deficiencies from frost and drought supplied. We may as well mention here, that we had to replace a lot of Bijou Geraniums, and it is well to know how the disappointment was occasioned. The plants had been drawn a little, and were higher than we wanted them, and, therefore, after planting the stems were bent so that they were left nearly horizontal instead of perpendicular. Now, of all these plants, though the bottoms were quite sound, the stems if not withered-up were blackened, and the skin parboiled as it were, from the double cause we presume of cold by night and extreme bright sun by day; whilst all the plants that were smaller and allowed to stand upright were quite right, and nothing at all the matter with them, though planted the same day in the same bed. Of course, the upright stems would neither be exposed to radiation of heat, nor evaporation of moisture like those bent horizontally. As bearing upon the same fact, we may mention that Verbenas planted out early, and which for a certain purpose were staked upright, suffered little or nothing; whilst those pegged down were blotched considerably, though they are coming all right.

We have now pretty well all the rough of our planting finished, and it would have been done before the end of last month but for the dry weather and the scarcity of water. Dahlias that were turned out in beds have lifted well, and though strong have scarcely felt the moving. For large tall kinds the holes are made, and the stakes secured before planting, so that a little fresh soil can be given to each plant, the plant secured to the stake, and a basin round it made and finished as we go, the ground about one row being nicely forked or moved before we proceed to a second. For dwarf Dahlias we use the rough twig stakes we adopt so generally for other purposes; but in planting them, as well as all other things, as Geraniums, Calceolarias, &c., needing support here—the one row is staked and tied, after planting, before the next is planted, and the ground kept stirred all the time. In all such staking after planting, it is a rule never to put the stick within 3 or 4 inches of the stem of the plant. Young beginners will stick it in close to the stem, and thus probably injure the best roots. Some young hands have had to be threatened not only to be tied to a stake, for that they would not mind for a joke, but to have the stake driven through their foot for security, and that they would find no joke. Such a mode of planting and tying, and stirring the ground, using boards for standing on instead of sinking ankle-deep in the ground, involves more labour and more time at the planting period, but it is found to be truly economical in the long run. A man may soon plant a bed or border if he merely slips the plant in with a trowel, careless how hard and trodden it may be in places; but we never found such wondrous quick planting very satisfactory in producing early results.

We may give more particulars as to planting and arrangements in a simpler way, in the meantime we will just mention a little matter which we have had a little trouble in carrying out. In planting beds or borders edged with grass or lawn, the planter is apt to stand on the very edge of the grass or, perhaps, part of his foot is on the grass and part on the soil, and in either case, if the work to be done requires much time, the verge outline is destroyed, and apt to be thrown into holes and hills, and no little labour is required to secure a regular plane outline. Now a long board laid on the verge of grass saves all this bother and unsightliness; but unless looked after the board is almost sure to be shirked or forgotten. No bed, however nicely planted, will look well if it has tattered irregular edgings.—E. F.

TRADE CATALOGUES RECEIVED.

B. S. Williams, Holloway.—*General Plant Catalogue, including Orchids, Ferns, New and Rare Plants.* 1863.

William Dillistone, Munro Nursery, Sible Hedingham, Essex.—*Catalogue of Choice New Plants of 1863.*

TO CORRESPONDENTS.

CLAYEY SOIL, TO RENDER POROUS (N. Markey).—Apply sea-sand and tart-mould as you propose, but before doing so pare and burn 9 inches in depth of the entire surface, and add the ashes to the sand and mould. This will at once improve the staple and destroy the slugs.

DOUBLE PYRETHRUMS (A Subscriber, Cirencester).—If the Pyrethrums are quite double they cannot be propagated from seed. The stamens and pistils are changed into petals.

TURNER'S GARDEN SCISSORS (A Constant Subscriber).—We cannot tell where these can be purchased, but we remember seeing them at a cutler's in London not long since.

SHIPPING AURICULAS (H. B.).—Do not shift your Auriculas now, for June is about the time when they take their summer rest; and if they were repotted now it is almost a certainty that not having circulation enough going on, they would damp-off and die. We speak from experience, having last year had to receive a collection just about this time. The result was that about one-half of them died! If we could have had them in May or waited until the end of July, we should have been able to have saved them all, as in May they would have been making growth and at the end of July would have been preparing for their autumn start. We, therefore, strongly advise you to leave your plants in 60's as they are. The trouble of watering is a very minor evil. With regard to fumigation, it is a practice we never indulge in with the Auricula. We never allow the aphid to get ahead, and that simply by using a camel's hair brush, or, what answers equally well, some pieces of bush tied together and made into the form of a brush. You may keep the green fly under without fumigation.

PANSY FLOWERS INJURED (L.).—Your Pansy blooms are devoured by some unseen enemy, which we suspect is either the small white slug or the woodlouse. If the former, the best plan is to go out at night and examine, armed with a lantern and your fingers. If the latter, place some pieces of Elder with the pith hollowed out, or two pieces of board kept about an eighth of an inch apart on the bed, and you will then trap them. We would advise you to try, if fond of the Pansy, to grow them in pots, as they are a very favourite food of many insects.

HARDY SEEDLING POTATO (Mada).—If you have a Potato the foliage of which you think sustains no injury from a frost which blackens the foliage of other varieties, it would be desirable to save its tubers for seed, and try rows of it side by side with other varieties. Such hardiness is a desideratum in early Potatoes.

ORANGE-TREE LEAVES FALLING (A Subscriber).—Your Oxbone Orange is suffering from one or more of the following causes:—Imperfect drainage; and a sour soil, caused by too much water, or from giving only a little at a time, but never enough to thoroughly moisten the ball of earth, or the brown scale may have closed the pores of the leaves and sucked out the sap. Any of the above will cause the Orange to throw off its leaves. You will determine for yourself which of the above causes are applicable to your case, and adopt a mode of treatment the opposite you have followed to effect a remedy. In your case we would turn the plant out of the pot, take away all the loose soil and as much soil from between the roots as it is possible to do without injuring them with a blunt-pointed stick, cutting on any decayed roots at the same time with a sharp knife. But if the roots are very much decayed, wash all the soil away from them: take away all the decayed parts, cutting well into the quick. Prepare a clean pot sufficiently large to prevent the roots from being cramped against the pot sides, but not larger than just to contain the roots comfortably. Place a large crock in the hole in the pot; and if that be small, make it larger with a hammer. Put for a twelve-inch pot 3 inches of smaller crocks at bottom of pot, or let the drainage occupy one-third of the depth of the pot, and on that place a little moss, or, what is better, half an inch of cow-dung more. Pot lightly, yet filling up all the crevices between the roots, and keep the neck of the plant well up, for the Orange, like the Camellia, soon becomes sticky when the roots are buried. Use three parts turfy loam and one-fourth leaf-mould, with a little rough sand intermixed. If the plant is infested with scale, paint with a brush all the shoots with a solution of Gishurst compound at a strength of 8 ozs. to the gallon of water. Should you have the convenience of a hotbed at a temperature of from 70° to 80°, your plant will be much benefited by being plunged there until it breaks out leaf, and none the worse if kept there until the wood is formed. The top heat may range from 65° to 85° for about six weeks, then it should be lowered so as to gradually harden-off the plant for the greenhouse—its proper place. If the plant be straggling or the shoots weak, cut them well back when the buds begin to swell, for the sap is then on the move and roots are beginning to form. Syringe gently twice a day—morning and evening—and keep the soil in the pot rather dry at first, grow more as growth progresses. If you have no hotbed, place the plant at the warmest end of the greenhouse, sprinkle it lightly morning and evening with tepid water, and although it will be longer before growth commences than by the former plan, yet it may possibly recover; and if it does, pray make a note of it and send it to this Journal, for no tree is so grossly maltreated and so little understood as the Orange. The after-treatment of the Orange is to pot in March, adding a little rotten manure to the compost mentioned before, and to keep the leaves and stems clean by frequent sponging with a weak solution of soft soap and water. Your Myrtle-leaved Orange is doing for itself what the cultivator ought to have done long since—judiciously thinned the branches in the centre of the tree, and so prevented their smothering each other. Well regulate the shoots by a copious thinning, and give the plant more light and air. Examine the roots and make all right there, and then we think you will have no difficulty in getting it to bloom and fruit profusely. You may have cropped your tree too heavily, and that would account for the tree being unfruitful this year, or you may have indulged it too much with liquid manure—one of the most fatal agents to weak-growing kinds of Oranges.

GRAPES SHAKING (G. Berry).—Most likely you have left too heavy a crop. Remove shaken berries and reduce some of the bunches. You might make a drain in front of the border at once if there is no one. It is ascertained that the roots are deep and that is the cause of shaking, as soon as the Grapes are cut raise the roots, replant at once, water with warm water, shade the house, keep the foliage green as long as possible, and the Vines will be all right next season.

AZALEAS AFTER FLOWERING (L. J. L.).—Azaleas, when they have finished flowering, will make their wood and set their buds best in a moderate hothouse a little shaded. Then they may afterwards have more air and be set out of doors.

PLANTS COUNTER-ORDERED (Five-years Subscriber).—You should have returned the plants; but now, we think, you have no remedy.

BUDDING VINES (H. M. H.).—Inarching is a much better plan than budding, and as it can be done at any time, it is more generally practised. If, however, you are anxious to try budding, an examination of the buds will enable you to judge when they are ready; and while the sap flows freely in both bud and stock it may be done. A certain amount of firmness in both the stock and the wood the bud is taken from will be necessary. The operation is the same as for fruit trees and Roses, tie-up with woollen or cotton yarn, the former preferable, and examine the bud in time to see that the ligature does not bind it too severely.

SEEDLING CALCEOLARIA (C. Daniel).—The flowers appear to belong to a fine strain of Calceolaria, both outline and marking being good; but, of course, flattened as they were, we could not tell if they have the requisite rotundity. The brightness of the colours was pressed out. As far as appearances go, under these circumstances Nos. 2 and 3 seem the best; but the day is gone by for treating herbaceous Calceolarias other than as annuals. The first thing is to get hold of a good strain as you seem to have done.

CAMELLIA AND AZALEA LEAVES (J. B. Croydon).—We like inquiries to be brief, but the facts to be definite. The briefness is all right; but we have nothing to guide us to a decision. The Camellia leaves seem to have been scorched by sun falling on them whilst moist, the roots being dry or improperly drained. The Azaleas retain signs of thrips, for which the best remedy is smoking and well syringing afterwards. The other part of a leaf may be a Miller's Burgundy Vine, or ever so many things. The holes may be made by caterpillars, insects, or sun stroke. Who can tell without some facts or information?

FLOWER-GARDEN PLAN (H. K. A. Manchester).—In the roominess of your garden there is much to admire. Your main group is formed of five figures—a centre triple-raised basket with a broad border round it, forming a circle altogether, we presume, of some 10 to 12 feet in diameter. Round that are two nearly half-moons and two circles. The widest part of the quarter-moons and of these outside circles is not more than half the width of the central circle. This fact, and in addition the raised baskets in the centre, will so rivet attention on the centre figure that the four outside figures will be drowned, or at least thrown into the shade. The first hint we would give would be the enlarging of these four outside figures, so as to balance in size the central one. The next would be to carry No. 1, at one end of the lawn, much farther along, so as to be a balance to No. 7 at the other end. Now as to the planting. We do not see how the planting of the centre No. 6, with its flat bed and three tiers of baskets, is to be improved, presuming that the Lobelia in the first basket is higher than the Perilla in the back row of the level bed. We think that to contrast with this Perilla such things as *Gnaphalium Larperina* or *Veitchiana* would have been better, and then the Lobelia might have edged the second basket of Calceolarias. By the way, Calceolarias are not the best for baskets—they are so greedy of the water-pail. In the four beds round there seems to be neither balancing of colours nor balancing of materials. One of the beds is scarlet *Geranium*, one Calceolaria—yellow, we presume—one scarlet *Verbena* edged with *Alyssum*, and the fourth purple. Now, as you have white *Cerastium* and variegated *Geraniums*, and Calceolarias and Perilla in the centre figure, it makes it something difficult to balance these four; but two scarlets and two purples would be better than at present, or for variety make each of these beds different—as scarlet, blue, yellow, purple, which would all come in with the centre bed of baskets. We think No. 1 must look well—Perilla, variegated *Geranium*, Calceolaria, and *Centaurea candidissima*; but if that is the planting leading from the centre, we think the following would improve it:—First outside, *Centaurea candidissima*; second row, scarlet *Geranium* with dark leaf, as *Village Maid* or *Excellence*; third row, yellow Calceolaria; centre, Perilla. Still we have no doubt your arrangement will do well, but perhaps we have a prejudice that yellow and white neither contrast nor harmonise well together. We think the large bed, No. 7, would be much improved with a broad edging of *Cerastium*, and if *Biscutaria* all the better—it would be a balance, though far off, of the *Centaurea* in No. 1; and the *Saponaria*, besides, does not make a good edging of a straight line, as it will creep among other things, and much pruning spoils the look of it. The rest we could not improve. Let us know how the *Amaranthus melancholicus* stands the season with you. We cannot say we like it so well as the Spinach.—R. F.

CAMPYLOPSIS REFLEGENS AND PATEITA BORBONICA (A Young Gardener).—They thrive in sandy loam and peat, and as they do not move fast enough, try and give them a little bottom heat and frequent dushings on the top with the syringe. A store of a moderate heat will suit them, and a mild horrid of the same heat.

APHELANDRA LEUCOPHYLLA (Idem).—The *Apheleandra* would be better of peat and sand pressed firm and a little loam added, which will give more consistence to the foliage. If not growing freely, a slight bottom heat would do it good. The flowering depends on free growth and a slight check to cause the flower-buds to form at the joints.

FAST-GROWING CREEPER FOR A RUSTIC BASKET (H. F. B.).—As the season is now late, *Cobaea scandens* will suit you best as a summer annual, or you might try *Mandragora Bardaniana*, the *Canary Tropaolium*, or a *Lophospermum*; the last named is not so robust as the others. But if a permanent creeper was wanted for a sheltered place, *Eccremocarpus scaber* will do; or still to be more permanent and to look well at all seasons, try some of the *Jasminums*, *Roses*,—or, perhaps, the best of all—Ivy, whose ever-beautiful green fully compensates for its lack of gay flowers. *Messrs. Lee's* white variegated *Geranium* is not yet brought out. If you write to them they will give you any information you need about it.

VINE LEAVES (An Amateur, Stratford).—The leaves were very much dried, but if it is not mildew we fear you have thrips. Examine closely, and see if you can discover any small jumping insects. If so, smoke as well as use the sulphur water; also use clear lime and soot water.

SOOT WATER (Idem).—Mr. Fish makes the latter by placing half a peck of soot or so in a barrel of water—say 50 gallons—and a quarter of a peck of fresh lime, working it up with a pail of water so as to mix, and then filling the barrel. In twenty-four hours the liquid will be as clear as brandy, and whilst syringing with it will hurt nothing, no insects of any kind like it. When the liquor from filling up gets too weak, add more soot and lime. Before using, remove any scum on the surface. This should not be used for fruit nearly ripe.

DOUBLE PANSY (J. Brown).—This seems to be the same as the Double Purple figured in "The Florist," where the colours are not well brought out.

NAMES OF FERNS (Henry, Haslewood).—The "Fern Manual," which will be published at our office on the 22nd, gives an interpretation of all the names. You can have it free by post for 6s. 2d. from our office.

YOUNG VINES NOT FLOURISHING (An Amateur, Nantwich).—All you have done and the soil appear quite correct, and the only suggestion we can make is that you have planted the Vines too deeply. The roots should have been spread out at about 6 inches from the soil's surface. If you have planted them deeper, take them up carefully as soon as the leaves begin to fade in the autumn and replant them. You must not use sulphur as you propose to kill the red spider. You had better dust the leaves with it, and keep the air more moist.

GRAPE BUNCHES DYING (D. B.).—If there have been no mice gnawing at the stems, the want of root-action is the cause of the Vine-blossom giving way. You should have the cause of two things, or both. The Vines being transplanted in November, the roots should have been encouraged to active progress by a heat of from 75° to 85° as soon or before the buds broke, and then only a moderate instead of a full crop should have been allowed to stand the first season. The more the roots are coaxed, and the less the branches are excited in such circumstances, the better. Most probably the Vines will be tempted by a night temperature not above 55° to 60°, and a slight shade in bright sunshine. No doubt the Trentham Vine in the orchard-house had either been deficient in root-power or you had kept the roots too dry, and therefore the stems gave. If not too late, examine the stems and roots below the ground are not nibbled. We have had several injured this season.

HERBACEOUS PLANTS—GRASSES, &c. (S. S. B.).—Your inquiry is too indefinite. We might fill some pages with names and not suit your purpose. Lists of herbaceous perennial plants have been given, and we are in a maze as to particularising. You had best select a few at first, as *Aquilegia* of kinds for spring and summer, average height 2½ feet; *Anemone* of kinds for early spring, and *Anemone japonica* for blooming in summer and autumn; *Delphiniums* of kinds, as *formosum*, *Hendersoni*, *Barlowi*, *grandiflora*, for summer and early autumn, from 2½ to 4½ feet; *Dielytra spectabilis*, for spring and early summer, 18 inches; *Gentiana acaulis*, for edgings in spring and summer, and the other kinds, from 1 to 1½ feet in height; *Helicopsis*, or *Christmas Rose*; *Lilium candidum* and others; *Gladiolus* in varieties, though it would be as well to raise the tubers; *Phlox*, a collection of hybrids; *Pansies* of kinds; *Lychnis* of kinds; *Potentillas*, yellow, scarlet, purple; *Saxifragas*, low-growing plants; *Silene* of kinds; *Spiraea* of kinds; *Veronics* of kinds. Then for grass-like plants we would recommend the *Pampas Grass*, the *Feathered Grass*, *Stipa pinnata*, and some six or ten more which your seedman considers most ornamental. Then for the foliage-plants we would instance *Purple Spinach*; the large *Atriplex hortensis*, purple; *Amaranthus melancholicus*, crimson purple; *Perilla nankensis*, dark purple; *Cineraria maritima*, silvery white; *Arctotis grandiflora*, white; *Alyssum variegatum*; *Centaurea candidissima*, requiring a warm greenhouse in winter; *Gnaphalium lanatum*, white, woolly, strong-growing, but needing protection from frost in winter; *Stachys lanata*, still more woolly and white, but coarser, though quite hardy; *Cerastium tomentosum*, small low plant, fine for edgings and beds. One year ago some edgings were placed round the sides of beds, raised by stakes and I try a foot or 15 inches above the ground, and from the end of March and onward to the end of June all round the bed, from the front upwards, has been a dense growth of white flowers, and when the time comes for the cutting there will be the white foliage. *Cerastium Biebersteinii* is a little stronger-growing, but otherwise seems to be no improvement. We might answer you better if we had more facts and details.

NAMES OF PLANTS (C.).—Apparently *Myosotis sylvatica*, but the specimen was much injured. (*B. A. S.*)—*Asperula arvensis*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

BATH AND WEST OF ENGLAND POULTRY EXHIBITION.

THAT the Poultry Exhibition connected with the Bath and West of England Agricultural Society of the present year is the best ever yet obtained under its auspices, cannot be open to difference of opinion, for not only were a greater number of pens entered than on any previous occasion, but we are much gratified to say, scarcely an indifferent pen could be pointed out after the most rigid inspection. The satisfaction of poultry amateurs will be increased on being assured that, without a single exception, every head of poultry was safely delivered at the show-yard, at Mount Radford, without the slightest mishap or injury to a single specimen, although lying about a mile from the Exeter Railway Stations. This naturally augurs well for the future success of this Society; and so far as scrupulous care and attention to the wants of the birds is concerned, no committee of management could be more worthy of public support. The Bath and West of England Agricultural Society has during a long course of years enjoyed a high position in public favour, having been first instituted so far back as the year 1777; consequently it is one of the oldest, if not the very oldest, of the agricultural societies extant. This year the Poultry Exhibition took place beneath two very large and commodious tents, which afforded by their peculiar arrangement a much better and more generally diffused light than we customarily meet with under like circumstances. To this necessary feature we attribute in

no small degree the evident ease and comfort displayed by the birds throughout the whole Exhibition.

As seems an almost general rule at such meetings, the *Spanish* class stood at the head of the list. It was very gratifying to find that nearly the whole of the birds in this class were of high merit, and their condition as a body was more favourable than we anticipated. The third prize by care and attention to condition might be shown to great advantage; they were evidently one of the best pens, but were over-shown, and were in the worst exhibition trim of any competing. The hens in the second-prize pen were first-rate, as were equally those in Pen 2, highly commended, but a falling comb in the cock was a fatal objection. Several other cocks had this failing.

The *Grey Dorkings* were a better class than ever exhibited at this Society's meetings on previous occasions, but, as might be expected, the adult birds are now fast falling into indifferent feather. Lady Holmesdale with an entry of three pens swept the board of all the three prizes, and obtained the silver cup also, for the best shown in classes 1 and 2. In the class for *Dorking chickens*, Mr. Wakefield showed a fine even pen, and took first; the second falling to Mr. Smith, of Salisbury, closely pressed by several exhibitors. The *Grey Dorking* chickens shown were the earliest and best plumed we have seen this year; and it was equally worthy of mention that none were shown with deformed feet and toes, a failing to which very early hatched *Grey Dorkings*, or, in fact, any weighty description of poultry, are very susceptible. This arises in chief from chickens hatched in the early spring months huddling together for warmth, without taking sufficient exercise; consequently their legs and feet fail them. The *White Dorkings* were as good a class as have been seen for years past—so good, indeed, that every pen entered was favourably noticed by the Judges.

Captain Heaton won first place with his well-known Partridge-coloured pen, pressed, however, more closely than usual by a most excellent pen of purely Lemon-coloured *Cochins*, so good, that we anticipate the £21 award would not prove a prohibitory price. They were shown by Mrs. Fookes. The *White Cochins* were perfect, Mr. Chase taking both the adult and chicken prizes.

In *Game* fowls every class was well filled with birds of the highest repute as prizetakers. Mr. Fletcher took a great proportion of the prizes. It was evident this gentleman had called heavily on his reserve forces for the Exeter Show, for every one of his pens was shown quite fresh, and, consequently, in faultless condition. The advantage of this practice contrasted with exhibiting birds week after week in succession never met with a more apt illustration.

As a whole, the *Game* classes were, without exception, well contested.

The *Malays* were the most out of condition that can be conceived, so ragged in plumage as to call forth much jocularity from visitors. We heard a young lady still in her teens exclaim, "Look at those fowls, the cock must have half plucked them, and then reprieved them till another time." Although the breed of many of the pens was unquestionable, it certainly would not have been any very great strain of justice had the class been disqualified altogether, as in not a few specimens, patches purely void of feathers of half the size of the hand were visible, calculated rather to shock than please the public. There is no just reason why *Malays* should not be exhibited in equally perfect plumage as other fowls.

The *Hamburghs* were really good in each of the four varieties. In the *Silver-spangled*, a "hen-feathered" cock was shown—a whimsicality we thought exploded long ago—his hens being without objection. The pen was necessarily disqualified.

The *Black Polands* were, as is always the case where Mr. Fenton Edwards exhibits, a very superior collection. We would suggest to the Council of the Bath and West of England Society, that in future the *Poland* class should be open to every variety, as by so doing the entries would be numerically fourfold, whilst the outlay to the Society would be unaltered, compared to, as now, its being restricted to *Black Polands* only.

The *Spanish chickens* that were shown foretell that future years will prove that this aristocratic variety is still not without the most careful culture.

Many of the *Bantams* were extraordinarily good—so much so, that the Judges felt bound to suggest an extra prize to the consideration of the Directors, which will, we believe, be conceded. Black ones secured the silver cup for the best pen of any breed of *Bantams* shown. They were excellent; but it was rumoured

among amateurs the address of the owner was assumed—a report scarcely credible, so long as even the number of the house is added to the general address in the printed catalogue.

The *Geese*, *Turkeys*, and *Ducks* were most praiseworthy. A pen of Grey Calls in the fancy variety of Ducks, was evidently quite the pet of the company, they were the best pen ever shown by Mr. Harvey Dutton Bayly. It was the subject of general remark, that though the same sum of money was offered as prizes for Buenos Ayrean Ducks as to any other breed, no entry whatever ensued. This is the more remarkable, as the southern counties have always excelled in their production, and the Bath and West of England Shows have usually called into competition some of the best of them. It should be remembered they are very ornamental, excellent in flavour, and easily reared, whilst as layers few breeds exceed them. They are, it is admitted, somewhat prone to stray from home, particularly when the temptation of some still-flowing river is within moderate flight; but this propensity is much modified by the manner of rearing them, and can be prevented altogether if they are pinioned; nor does this latter arrangement seem to interfere at all with their comforts or productiveness if carried into operation whilst ducklings. Among the Rouens shown were many exceedingly large and well-marked birds, but dark bills are quite inadmissible, however perfect otherwise. In a pen of this kind the owner exhibited two drakes and two Ducks, which naturally led to disqualification. Rules must be enforced.

Among the curiosities that was not unfrequently find an entrance into the Any variety class, was a pen of four hybrids, the product between the common English wild Pheasant and the domestic fowl. They apparently elicited more attention from visitors than any other single pen in the whole collection, and certainly they were unusually interesting. To most of our readers it is well known such hybrids are invariably mules, being alike sterile, or *inter se*. It may, therefore, with justice be said, that their only useful position is the exhibition pen. As a rule, the birds that are thus produced by an intermixture of the fowl and Pheasant vary from each other extraordinarily in plumage; but in the case now named, the fowls in the best-selected pen in the whole Exhibition could not have matched more perfectly. They were *fac-similes* of each other, and certainly this trait of character added most materially to the interest of the pen—so much so, that it was constantly surrounded by inquiring visitors. Although the lustrous copper colour of their general plumage renders these hybrids so pleasing to the eye, those hitherto who kept such specimens have generally at length been obliged to do away with them as intolerable, on account of their inveterate egg-eating propensities.

This extra class brought into competition some excellent Crève Coeurs, Brahmas, Black Hamburgs, and White Spanish fowls. The neighbourhood of Exeter has for many years been celebrated for excellent specimens of this last-named singular variety. They are reputedly excellent layers, but we should imagine not equal to the Black Spanish, nor do we deem them as being of equally hardy constitution.

There was a very creditable display of *Game Bantams*, though just at this period of the year it is not by any means the best time for exhibiting them. The Seabrights were especially good, the Silver-laced having quite the advantage as to perfection of lacing.

Some very beautiful little birds, that to casual visitors "seemed to have no legs at all," were exhibited as *Japanese Mufflers*. We should fancy them the best calculated of any fowls we have yet seen for the rearing of Californian Quails, or any of the many varieties of Partridges.

There is always a very warm competition at the Bath and West of England Society's Show as to *Pigeons*, and this year's Show proved no deviation. It is very rarely that Pigeon-breeders have so great a treat afforded them as the Show just closed at Exeter. When it is taken into consideration that most fancy Pigeons are now breeding, the merit of obtaining such a collection is obvious, whilst it proves this year's liberal prize schedule was generally appreciated. We noticed particularly a class of Bunts comprising nearly every known variety of colour; Black Mottles, Blues, Silver Duns, being here all shown in the highest perfection. The perfection of plumage of some of the pens of Archangels must not pass unnoticed. The classes for both Almonds and for Short-faced Tumblers were well filled. Among the Barbs were some of the best-headed birds we ever yet met with, the class generally being both numerous and good. The

Carriers were a grand collection, and the Powers were a class good throughout. We were especially pleased with the Turbits, as of late this beautiful variety of Pigeon has been very scantily exhibited. The competition in the class for Fantails was great, and the Any variety class was replete with numerous and exceedingly good specimens.

A remarkable feature of this Show was, that not a single case of disease was observable throughout the whole collection; and if care and attention can insure its continuance, we are satisfied owners will be gratified on the return of their poultry.

SPANISH.—First, Viscountess Holmesdale, Linton Park, Staplehurst. Second, H. B. Kite, Exeter. Third, Brown, Sheffield. Highly Commended, R. Wright, Highgate; Rev. G. F. Hodson, North Petheriton, Bridgwater.

DORING (Coloured).—First and Silver Cup (as extra prize for the best pen of Black Spanish, or Grey Doring exhibited, Second, and Third, Viscountess Holmesdale, Linton Park. Highly Commended, Miss Milward, Bristol. Commended, W. Watson, Calstock, Cornwall; W. Vickers, Exeter; J. K. Fowler, Aylesbury; Major Altham, Taunton.

DOCKING (White).—First, Mrs. H. Fookes, Whitechurch, Blandford. Second, Mrs. Beadmore, Farnham, Hants. Third, Rev. G. F. Hodson, Bridgwater. Commended, Mrs. Beadmore; Rev. G. F. Hodson.

COCHIN-CHINA (Coloured).—First, Captain Beaton, Manchester. Second, Mrs. H. Fookes, Whitechurch, Blandford. Third, B. T. Ford, Exeter. Highly Commended, W. Vickers, Exeter.

COCHIN-CHINA (White).—First and Third, R. Chase, Balsall Heath, Birmingham. Second, F. W. Zurichst, Dublin.

GAME (White and Pile, &c.).—First, J. Fletcher, Stoneclough, Manchester. Second, H. Adams, Beverley. Third, W. Dawson, Birmingham. Highly Commended, Rev. G. S. Cruwys, Tiverton. Commended, M. Billing, jun., Birmingham.

JUN (Black-breasted and other Reds).—First and Silver Cup (as an extra prize for the best pen of Gamefowls exhibited, and Third, J. Fletcher, Stoneclough, Manchester. Second, H. Adams, Beverley. Highly Commended, W. Watson, Calstock, Cornwall; W. Boyes, Beverley; Rev. G. S. Cruwys; Rev. F. Watson, Woodbridge, Suffolk; S. Matthew, Stowmarket, Suffolk; M. Billing, jun., Birmingham. Commended, W. Watson; W. T. Everard, Abby-de-la-Zouch; W. D. Braginton, Akeford, Devon; H. Adney, Lympstone, Exeter.

GAME (Duckwings and other Greys and Blues).—First, F. Fletcher, Stoneclough, Manchester. Second, H. Adams, Beverley. Third, Rev. G. S. Cruwys, Tiverton.

MALAY (Coloured or White).—First, W. Sykes, jun., Mile End, London. Second, J. J. Fox, Devizes, Wilts. Third, W. Mansfield, jun., Portesham, Dorchester.

HAMBURG (Golden and Pencilled).—First, J. E. Powers, Biggleswade. Second, H. Beidon, Bradford, Yorkshire. Highly Commended, N. Barter, Plymouth.

HAMBURG (Silver-pencilled).—First, Viscountess Holmesdale, Linton Park, Staplehurst. Second, H. Beidon, Bradford, Yorkshire. Highly Commended, T. W. Walsh, Worcester.

HAMBURG (Gold or Silver-spangled).—First, I. Davies, Harborne, Birmingham (Golden). Second, T. Davies, Newport (Silver). Commended, H. Beidon, Bradford.

POULTS (Black, with White Crests).—First and Second, T. P. Edwards, Lyndhurst, Hants.

ANY OTHER VARIETY.—First, Miss S. H. Northcote, Upton Pyne, Exeter (F. White Spanish). Second, F. E. Collier, Salisbury, Wiltshire. Third, E. Pigeon, Lympstone, Exeter (Crève Coeur). Highly Commended, C. Langley, Chudleigh, Devon (hybrid between red Game cock and hen Pheasant); E. Pigeon (Brahmas); H. Beidon, Bradford, Yorkshire (Gold Pouter). Commended, J. Pates, Chertsey, Surrey (Brahma Foot); J. W. Fowler, Aylesbury (Brahma Foot); S. Dupe.

SPANISH CHICKENS (Black or White).—First and Second, J. R. Rodbard, Winton, Somerset. Commended, J. K. Fowler, Aylesbury.

DORING CHICKENS (Any variety).—First, C. H. Wakefield, Malvern Wells. Second, C. Smith, Durnford, Salisbury. Commended, W. Watson, Calstock, Cornwall; Miss Wilcox, Bristol.

GAME CHICKENS (Any variety).—First, H. Adney, Lympstone, Exeter. Second, J. Fletcher, Stoneclough, Manchester. Highly Commended, H. Adney; W. Rogers, Woodbridge, Suffolk.

COCHIN-CHINA CHICKENS (Any variety).—First, R. Chase, Birmingham. Second, J. K. Fowler, Aylesbury. Highly Commended, W. Vickers, St. Sidwell's, Exeter.

SWEETSTAKES.

GAME.—First and Silver Cup (as an extra prize for the best Game cock, Spanish, Dorking, Cochon-China, or any Game cock), J. Fletcher, Stoneclough, Manchester. Second, H. Adams, Beverley, Yorkshire. Third, W. Boyes, Beverley, Yorkshire. Highly Commended, J. Fletcher; H. Adams; S. Matthew, Stowmarket, Suffolk; M. Billing, jun., Birmingham. Commended, Rev. G. S. Cruwys, Tiverton.

DORING.—Prize, Viscountess Holmesdale, Linton Park, Staplehurst.

SPANISH.—Prize, Rev. G. F. Hodson, Bridgwater. Highly Commended, S. C. B. Pitman, Taunton.

GAME BANTAM.—First, T. H. D. Bayly, Biggleswade. Second, W. Sykes, jun., Mile End, London. Third, J. Camm, Farnfield, Wilts.

BANTAMS (Gold-laced).—First, T. H. D. Bayly, Biggleswade. Second, Rev. G. S. Cruwys, Tiverton.

BANTAMS (Silver-laced).—First, R. Chase, Birmingham. Second, T. H. D. Bayly, Biggleswade.

BANTAMS (White and Black).—Extra Prize, Mrs. H. Fookes, Whitechurch. First and Silver Cup (as an extra prize for the best pen of Bantams of any variety exhibited. It was awarded to Black ones), Miss K. Charlton, Bradford, Yorkshire. Second, Rev. G. S. Cruwys, Tiverton. Highly Commended, Rev. G. S. Cruwys. Commended, K. Brotherton, jun., Almondsbury, Bristol.

BANTAMS (Game).—First, T. H. D. Bayly, Biggleswade. Second, J. Camm, Southwell, Notts. Highly Commended, J. Camm; W. A. Deane, Bideford, Devon. Commended, W. A. Deane; E. Pigeon, Lympstone, Exeter; K. Brotherton, jun., Almondsbury, Bristol.

Ducks (White Aylesbury).—First and Silver Cup for the best pen of Ducks exhibited, J. K. Fowler, Aylesbury. Second, F. W. Fowler. Commended, G. Hanks, Malmesbury.

Ducks (Rouen).—First, J. R. Rodbard, Wroughton, Somerset. Second, G. Hanks, Malmesbury.

Ducks (Any other variety).—First, T. H. D. Bayly, Eiggleswade.

Geese.—First, J. W. Fowler, Aylesbury (Toulouse). Second, W. Manfield, jun., Portesham and Dorchester (Improved Dorset).

Turkeys.—First, Miss Milward, Bristol. Second, W. Manfield, jun., Portesham and Dorchester (Bronze). Highly Commended, Mrs. N. Grenville, Glastonbury (White).

Guinea Fowls.—First, Miss S. H. Northcote, Upton Pyne, Exeter. Second, H. Adney, Lympstone, Exeter. Commended, S. C. E. Pitman, Taunton.

PIGEONS.

CARRIERS.—First and Second, F. G. Stevens, Axminster.

ALMOND TUMBLERS.—First, F. G. Stevens, Axminster. Second, F. Else, Bayswater, London.

TUMBLERS.—First, F. Else, Bayswater. Second, F. G. Stevens, Axminster.

POWERS.—First, F. G. Stevens, Axminster. Second, R. Fulton, Deptford.

RUNTS.—First, F. G. Stevens, Axminster. Second, T. D. Green, Saffron Walden.

JACOBIANS.—First and Second, F. G. Stevens, Axminster.

FANTAILS.—First, F. Wey, Beverley, Yorkshire. Second, F. G. Stevens, Axminster.

OWLS.—First, E. Joblin, Newcastle-on-Tyne. Second, F. Else, Bayswater.

TRUMPETERS.—First, F. Key, Beverley, Yorkshire. Second, F. G. Stevens, Axminster.

BARBS.—First and Second, F. G. Stevens, Axminster.

TURBITS.—First, F. G. Stevens, Axminster. Second, E. M. Pierce, Taunton.

NUNS.—First, Rev. A. G. Brooke, Salop. Second, F. G. Stevens, Axminster.

DRAGONS.—First and Second, H. Yardley, Birmingham.

ARCHANGELS.—First, E. M. Pierce, Taunton. Second, H. Yardley, Birmingham.

ANY OTHER VARIETY.—First, F. G. Stevens, Axminster (new variety). Second, E. Pigeon, Lympstone, Exeter (Pouting Horsemen).

The Judges of *Poultry* were Charles Ballance, Esq., of Mount Terrace, Taunton; and Edward Hewitt, Esq., of Sparkbrook, near Birmingham. The *Pigeon* prizes were awarded by Dr. Cottle, of Cheltenham.

"B. & W.'s" APIARY.

(Continued from page 335.)

"As to the utility of drone-breeding queens in spring," against which your correspondent "INVESTIGATOR" decides, I am much inclined to agree with him from my own actual experience this year, although I may yet have something to say in favour of them before autumn comes. I have largely tried those drone-breeders, and while fully agreeing with "A DEVONSHIRE BEE-KEEPER," that the drones to which they give birth are capable of impregnating queens, I have found them practically useless. It is a very rare thing indeed to see drones in an apiary before the middle of April, nor are they usually seen in any numbers till the second week in May. But I presume that the existence of a very small number of vigorous drones would authorise one to expect that the wants of a virgin queen would not pass unheeded: therefore, if I had had no drone-breeding queens in my apiary, everything would have happened much as it actually has done with me.

But let me go to facts; and here I will beg your readers to turn to page 335. My absence from home prevented me from observing anything in my apiary during the month ending the 16th of May. That day I found everything going on apparently well with all my hives. A, D, E, H, and I, were very populous and active, and pollen was being carried into B and F. These two hives, therefore, had again supplied themselves artificially with queens. The queen of F would be hatched about the 18th of April, and the queen of B about the 24th. The question was, Would they be impregnated by the Italian drones, of which there were then, and still are, about two dozen in F, while, so far as I can tell, there were no other drones in the apiary? The only answer I can give is, that on examining F on the 27th of May, I found again a quantity of drone-brood, and plenty of full-sized drones, pure Italians, but no sign of worker-brood—a drone-breeding queen again. B I examined on the 2nd of June and found all well, with plenty of worker-brood sealed up, but I know not yet whether young bees show any marks of an Italian origin, and, indeed, but few of them can yet be hatched. It is this hive which I have in mind, when I say above, that "I may yet have something to say in favour of" drone-breeders in spring.

* I did not perceive drones in any save the drone-breeding hives till the 30th of May.

Before I conclude this paper I may as well copy from my note-book the remainder of my bee-practice hitherto. Resolving to try once more my luck with the Italians, I drove the whole adult population of A into a hive half full of empty comb, depriving them, however, of their queen (my pure Italian), which I returned to her now-deserted home, which was set in the vacant place, C. I had previously taken out of it a good piece of comb containing eggs and worker-brood of all ages. This was adjusted in a box and placed over the driven bees of A, which immediately set to work to repair their queen's loss. C, which was full of brood, is now pretty strong again, breeding fast, and comb-making. The bees of A did so well that I heard as many as three or four young queens piping in harmony on the 30th of May, and on Monday, June 1st, they swarmed naturally, two young queens going off with the swarm, one of which was, of course, sacrificed. This swarm is now G. I also succeeded in capturing one other of these, all of them being beautifully-marked young Italian queens, which I successfully gave to F, after a grand hunt for, and removal of, their drone-breeding mother. Thus A, F, and G are supplied with well-marked Italians, all of the same age. I also picked up no less than five dead queens under A, which were sacrificed before I could save them.

Out of D and H (see page 335) I made another swarm on the 27th of May, on Langstroth's plan, by driving D with its queen and adult population into a box full of empty comb. Then putting D with its brood in place of straw hive H, which was shifted to another stand in my garden. Everything is now (June 6th) going on as satisfactorily as I could wish, my bees standing in the following order:—

A. Pure young Italian queen. Born June 1st, 1863.	B. Young English queen. Born about April 24th, 1863.	C. Pure Italian queen. Born, 1862. (Late A.)
D. Hybrid Italian queen. Born, 1861.	E. English queen. Born, 1861.	F. Pure Italian queen. (Sister to A's queen.) Weak in bees.
G. Pure Italian queen. (Sister to A's queen.) Swarmed June 1st.	H. Box-hive in garden, now raising a queen out of D's brood.	J. Strong English queen. (Straw hive.) Born, 1861.
K. Same as J. (Late H.) Born, 1861.		

—B. & W.

TAKING A SIDE-COMB.

Surrey Highlander will be glad to know whether one side-bar may be safely taken from a well-stocked frame-hive a few days after a swarm issues from the hive. The side-bar was furnished with a sheet of embossed wax, and placed in the hive early in October last, when the bees immediately built upon it. Is it too early in the season now to ascertain whether they have filled the comb with honey?

[The comb could be better spared and would be more speedily replaced by the bees if taken previous to instead of after the issue of a swarm; added to which, if any comb be made after the departure of the old queen, and before her successor is impregnated, it will certainly be drone-comb. The proposed examination might have been made as early as April without injury if the middle of a fine day had been selected.]

DZIERZON ON FEEDING BEES—THEIR CHANGING SYRUP INTO HONEY.

IN the following masterly article on bee-feeding, its distinguished author appears really to have exhausted the subject. It will be perceived also, that he fully confirms the opinions with regard to the change effected by bees in artificial food, which have been so frequently enunciated in the pages of *THE JOURNAL OF HORTICULTURE* by—A DEVONSHIRE BEE-KEEPER.

ON FEEDING BEES.

Feeding bees can only be considered a necessary evil, with which the true bee-keeper who always keeps strong stocks has very little to do. He, however, who keeps bees in a locality not particularly favourable to the pursuit will, if he aim at increasing the number of his stocks, often be obliged to have recourse to feeding. Now, as last year, notwithstanding its promising appearance at the commencement, turned out unusually

bad for bees, owing to cold and wet setting in just at the critical period; it has been necessary to feed both in the autumn and in spring; and it may not, therefore, be amiss at this time to say something on the subject.

It is well known that food may be given to bees with a two-fold object: either to keep them alive until such time as nature again provides food and they are able to help themselves, or to stir them up to greater activity and promote breeding, which is frequently done in spring, until about swarming time. The former we call feeding of necessity; and the latter speculative feeding; and the question is how, when, and wherewith we must feed in order to attain both these ends in the surest, simplest, and cheapest way.

Feeding of Necessity must commence in autumn if the stocks have not such provisions that they may reasonably be expected to survive even a long and severe winter. Properly speaking, such feeding is disadvantageous to, and rather to be avoided by, a bee-keeper who has already a numerous apiary, and does not, therefore, stick at a few stocks. Such light colonies generally consume more than they are worth in spring, so that even in the most fortunate case no profit can be derived from them; but if they perish in an unfavourable season, food and trouble are alike lost, and even the combs are no longer useful—at least they are not of so much value as they would have been if the bees had been expelled by driving and added to other stocks.

It is easily understood why a beginner who wishes to multiply his hives tries to winter light stocks; and if they have only a warm dwelling, a good queen, and sufficient bees, they well deserve it, since if the next year be favourable they will repay tenfold the food bestowed upon them.

The best and most natural mode of provisioning light stocks is by inserting sealed combs immediately beside or directly above the seat of the bees, so that they may be able even in the coldest weather to reach the store without meeting with any empty combs, which at such a time they would not traverse. This operation may also be performed late, even in mild days in December, if one knows how to do it cautiously without disturbing the bees. Either place one or more combs just above the nest of the bees (the position is quite immaterial), by removing a part of the hive-cover, and filling any empty space with dry moss before replacing it, or take empty combs from the side until either the honey-store or the bees' nest is reached, and insert one or two sealed combs in their place. Possibly everything may be set right, and the hives closed before the cluster of bees begins to disperse. If the honeycombs at our disposal are not sufficient for all the stocks, the weakest may at least be furnished with them, and pieces of sugarcandy be laid on the bars of the stronger ones. When feeding with sugarcandy it must be remembered that it is only available for the bees if the apiarian or their hive provides them with the moisture required to dissolve it. Bees winter best on this kind of food when it is placed immediately under the well-cemented and somewhat cool top of the hive, so that the condensed moisture may not be absorbed by the wood. The twin-stock in particular, with its low honey-room, is arranged conveniently for it. In standard stocks it is well to remove the combs and the seat of the bees in the autumn from the middle to the upper compartment. If then a space of 1 to 2 inches high remains between the combs and the crown-board a good quantity of sugarcandy may be placed there, and when this is consumed a new store may be given. The opening at the top must be shut as close as possible, lest a current of air should abstract both warmth and moisture. Moss, which is a particularly warm substance, is especially adapted for filling every cavity. It need not be quite dry, and when feeding with sugarcandy it may sometimes be purposely wetted in order that it may produce moisture in the hives, or that the bees may be able to suck directly from it as from a sponge, or we may pour water into an empty comb and place this beside the sugarcandy. If many unfortunate attempts and experiments have been made in feeding with sugarcandy, the cause has been that this food has been given to stocks which were too weak to produce the requisite warmth, or perhaps it was not put in the right position and in the right place, or more probably that the bees were allowed to die from thirst. Although a superfluity of moisture within the hive is not desirable, since mouldiness and decay arise from it, yet its absence is certain destruction when the bees have nothing but dry sugar or crystallised honey. It is easier for them to dispose of a superfluity of moisture even in cold weather, than to search for water,

to suck it up and bring it home. Bees in want of moisture fly out even at a low temperature, and as they search for it also within the hive, many die both inside and outside their dwelling, whilst in consequence of the frequent disturbance, the whole stock is early seized by dysentery and perishes.

It is much more difficult to furnish the necessary food to light stocks when their combs are immovable. Straw hives with wide central apertures at the top may be provisioned by setting on them small supers with full combs; but if the feeding be somewhat late, one or two pieces of honeycomb or sugarcandy must be inserted through the opening, in order to bring the combs into direct communication with one another, otherwise the bees will not move upwards during cold weather, but die from hunger after consuming the provisions within the hive. Also, a small box containing a quantity of sugarcandy may be put over the aperture in the top of a straw hive; or large sealed honeycombs might be inserted in the hives themselves, by cutting away empty side-combs and fitting full ones in their place supported by small sticks, leaving the hive inverted during the night, and not replacing it until the combs have been properly fastened by the bees. As, however, many sealed cells are generally opened and the honey carried off, they perhaps, derive no more benefit than if fed with fluid honey.

If, however, one cannot furnish the bees with other food, such fluid honey ought to be given in time whilst they can fly a little, secrete wax, and are able to seal at least the greater part of the honey presented to them; since stocks with too many unsealed honey-cells generally suffer much in winter.

Combs with a great deal of unsealed honey are much colder to bees, whilst the exposed honey deteriorates in quality, attracts according to circumstances too much moisture, and becomes sour, or evaporates and becomes thick. At all events, it loses its aroma, and becomes disagreeable to bees, but especially so to man. If after bad years one should be obliged in the autumn to have recourse to other substances, such as dissolved sugar, malt, or potato syrup, treacle, or other sweets, feeding must be hastened and finished whilst the bees are still gathering, and by taking pollen have the power to purify these sweets and to change them into honey, although of an inferior quality. If the winter be favourable, and the bees are allowed to take flight from time to time for the purpose of cleaning themselves, one may bring the stocks through the winter; whereas in a long and severe winter they suffer as much, or may even perish, as if they had nothing but the honey gathered late in the autumn from the pine, fir tree, or from other so-called honeydew.

If bees should have consumed an unusual quantity during a severe winter, or if they have been fed too sparingly in autumn, much may be done during mild days in winter. Or with hives, such as the twin-stock, which can easily be moved, one may push honeycombs close to the bees' nest, and add new pieces of sugarcandy or honeycomb, &c. A disturbance if it take place but once, is of no consequence; under some circumstances it may even be an advantage, as the bees may then take the opportunity of bringing provisions into their nests, or of moving after their stores. But continued and repeated disturbances must be avoided, because they cause the bees to consume more food, and to suck up the moisture which condenses on the combs and the walls of the hive, and which may produce dysentery, and because when again congregating many bees remain behind and die from cold.

Speculative Feeding.—In this we have a different, almost an opposite intention, and a contrary mode of proceeding is, therefore, practised. Whilst the food given from necessity is administered in as large quantities as possible, in order to avoid frequent excitement and the commencement of breeding, and to insure this end one may even confine the queen, in speculative feeding an increased activity and more rapid breeding are the very points aimed at. The latter is most favoured by an uninterrupted and moderate pasturage, for whilst too rich a pasturage fills the brood-cells with too much honey, the entire want of it discourages the bees, and reduces them to inaction, and to cease breeding altogether. In imitation of a moderate pasturage, the food is either given repeatedly in small quantities, or so that they can dissolve and store but small portions. It is offered to them in a condition that renders it somewhat difficult to dissolve—such as candied honey, sugarcandy, or moist sugar, and the best place for it is below the combs (on the floor-board in lager-stocks), in order to cause the bees to come down and cover a larger number of brood-cells. Of course, a supply of moisture to liquefy the food, and which is indispensable in the preparation

of nutriment for the brood, must be cared for, especially if it should not condense sufficiently on the cool floor-board at a time when the bees are not able to fly out. Although for feeding of necessity in autumn, or even in winter, pure honey is in all cases the best; yet, when feeding on speculation, a mixture of honey and wort thickened by boiling, and afterwards, when the bees have become accustomed to it, merely thin malt syrup mixed with brown or any other kind of cheap sugar, may even be preferred; for this being a substance which requires to be changed into honey, calls the bees into activity, and excites them more. As it also contains more nitrogen it may, under certain circumstances—for instance, when the bees are not able to collect much pollen, promote breeding more than feeding with pure honey.

He who has the opportunity of making wort, or of obtaining it from a neighbouring brewery (of course, without hops or dregs) may prepare a cheap and good food for bees. The wort should be boiled a few hours, and when the mucilage has curdled and whilst simmering is formed into flakes it must be strained, again boiled, and mixed with honey or sugar. Once accustomed to it, the bees will take it without this addition. In an isolated apiary the food may be given during warm weather in the open air in troughs, water-tight boxes, &c. Of course, the surface of the food must be covered with wooden chips or straw lest the bees should drown therein, for they set about appropriating the gift in large numbers when they have once become accustomed to this mode of feeding. In a large apiary, however, such feeding in the open air causes too great a tumult and uproar, so that weak stocks hearing the swarm tune might be induced to rush out and desert their hives; wherefore, it is advisable, especially in early spring, to give to every stock its proper portion. Hives with moveable combs require no particular vessel for feeding, as the food may easily be poured into the cells of one or more combs, and inserted in the hive, or packed under the seat of the bees. As, however, on account of the nitrogen which it contains, the bees require pollen for the preparation of food for their brood, or, at least, are not able long to do without it, it becomes necessary to give them flour as a substitute when they are not able to collect it. This is best done in old combs placed in a sunny and sheltered spot near the bee-hives.

But if speculative feeding is to be of any real advantage, and food and trouble not entirely thrown away, it must not be begun too early; for whilst the air and the ground remain cold thousands of bees are enticed out of their hives and led to their death, so that though wishing to bring the stocks forward they are in reality only thrown farther back.

By speculative feeding before their stores are exhausted, bees are led into a certain error—they are induced to believe that pasturage for them already exists, which however, is yet wanting, and such an error in most cases brings with it its own punishment. Yet the excitement and activity produced by this delusion may also, in many cases, be of great advantage; for instance, if a driven swarm has been made, and we wish the bees to begin many royal cells, but unfavourable weather setting in threatens to defeat the intention; we wish for very early drones, and, perhaps, early and true young Italian queens; or drone-brood exists in the desired quantity, and when bad weather comes there is a risk of its being torn out; we have divided a stock and taken rather too many bees from it, so that it is to be feared that part of the brood may die before many young bees hatch out—in these and similar cases speculative feeding in order to increase the spirit and activity of the bees, and ward off the evils threatened by unfavourable weather will certainly be of use. Generally, however, little is gained by feeding, and my conviction is, that much, very much, honey is wasted by it. It is better to keep heavier stocks through the winter than to feed light ones afterwards. Consider feeding always an evil, and restrict it to the most pressing cases. Especially never feed on speculation, so as to lure bees into activity before the proper time, but at the utmost only in order to fill up gaps and pauses in the already-begun pasturage, and to keep breeding when fairly commenced in steady and uniform progress.—DZIERZON.

EXHIBITION OF BEES.

A NOVEL feature in the Exhibition of the Bath and West of England Agricultural Society which took place at Exeter last week, was the stall of Messrs. Neighbour & Sons, in which were exhibited bees at work, bee-hives, and apian appliances of every

description. There were two Ligurian stocks of bees at work, one in a full-sized Woodbury uncomb-hive, having been brought from London for the occasion, and the other in a smaller hive of the same description, being from the neighbouring apiary of our valued correspondent "A DEVONSHIRE BEE-KEEPER." Amongst the hives exhibited, the Woodbury frame-hive in straw appeared both novel and good, whilst amongst the apparatus artificial combs and the stereotyped plates for making them seemed to us the most worthy of attention.

There was a remarkably curious specimen of artificial comb or partition-wall partially fabricated into complete comb by the bees, which struck us as being well worth examination, showing as it did the various stages by which this transformation is effected, and being calculated to throw light on the problem as to the mode in which bees construct their combs. It is almost unnecessary to state, that this unique and instructive stall was crowded throughout the week, and we hope its financial results were such as will lead Messrs. Neighbour to continue their attendance at the Society's meetings.

BEES DYING.

ONE of my hives of bees during the late warm weather showed indications of swarming by hanging in large clusters from the floor-board. While I was watching them, a portion (say a fourth), fell to the ground dead. On the following day I put on a super to prevent swarming, into which they ascended and commenced work. On examining the super after the late rain, I found all the bees in it dead. Can you tell me the cause? The hive was well protected from the rain and cold. The stock was a weak and late swarm of last year, but well fed during the winter and spring. I have also observed the old bees carrying away the white grub.—CLARA NOODLE.

[Your bees probably died of starvation. See what is said below by "A. W."]

LIGURIAN BEES IN AUSTRALIA.

IN a letter which I have recently received from Mr. Edward Wilson, President of the Acclimatisation Society of Victoria, that gentleman says:—"You will be glad to hear still further good news of your Ligurian bees. By the last mail I hear that from one of the hives, three fresh stocks have been already formed, raising our number to six, and offering fine prospects for the spring. All the gentlemen who have had these bees under their charge are delighted at their manifest superiority over the common bee."

I need scarcely add how much pleasure it gives me to learn that my little favourites are vindicating their high character at the antipodes; and how ardently I trust that they may amply repay, by their prosperity, all the care which has been lavished upon them since their arrival in the colony.—A DEVONSHIRE BEE-KEEPER.

THE BEE-SEASON IN SOUTH DURHAM.

"WARSAW am Warsaw," as the Israelite said. This season makes the fourth bad one for bees, and I find very many hives have died out; and only about ten days since I saved one of mine in a box-hive by feeding and wrapping it up, as I fancied it was dying from both cold and starvation. From my inquiries, I should say half the bees have died in this part (South Durham) last winter and spring. It would appear that they have made very little honey up to this time (9th June); and I do not observe that they have frequented the May this season, and, therefore, suppose there is no honey to be had from it.

Many of your correspondents would be glad to have reports from bee-keepers in different parts of the country as to their success or failures.—A. W.

OUR LETTER BOX.

IS SALSIFY A POISON FOR FOWLS?—*Mada* has lost several hens and a cock, apparently of indigestion, and the only cause to which he can attribute it is his having thrown some roots of Salsify on to the rubbish heap. We do not think that, either raw or cooked, the roots would be poisonous, for we are not aware of any species in the genus that is deleterious.

BEES (C. C.).—For Ligurians apply to T. Woodbury, Esq., Mount Radford, Exeter. A new edition of our "Bee-keeping for the Many," much enlarged and with numerous illustrations, will be published in a few days.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 73.0° and 51.3° respectively. The greatest heat, 93°, occurred on the 27th, in 1826; and the lowest cold, 34°, on the 24th, in 1859. During the period 141 days were fine, and on 111 rain fell.

USING THE WATERING-POT.

(Concluded from page 428.)

HE uses and abuses of the watering-pot as regards ordinary kitchen-garden crops and deciduous trees having been already detailed, it is only necessary to say a few words on it in its relation to evergreens, and I shall then proceed to consider its influence on the well-being of potted plants.

Its duties with regard to evergreens are somewhat different from those required by deciduous trees. As with these foliage is as

much a feeding-medium as the roots, and as most evergreens thrive best when partly in the shade, it is advisable on all occasions to shade the roots, or rather the ground the shrubs are planted in, after watering, in order to retain as much moisture in the ground as possible. Thereby in some degree we copy the design of nature, which invariably shades the space occupied by the roots of an evergreen by its own boughs. Thus, therefore, after watering newly-planted evergreens let them be shaded, or, what is better, covered with moss, litter, short grass, leaf-mould, or something that will prevent the direct action of the sun upon the ground and check evaporation. Rhododendrons, perhaps more than any other plant, require this to be done; even established plants that do not occupy the whole ground will be the better if the ground is shaded or covered in some way during the hottest part of the season. All newly-planted evergreens, too, or such as from necessity have been planted at a wrong season, are much refreshed by having their foliage sprinkled with water during the evenings—after the sun has left them, of course.

We now come to what is by far the most important use of the watering-pot—namely, supplying potted plants with their daily drink; for their artificial condition necessitates this, and it is here that the judgment of the operator is called into exercise. Any mere labourer can carry water and pour a large quantity of it where told, but some discretion is necessary to judge of the quantity required by each plant.

Serving all alike (a plan much too common), is death to a great many plants, while, unfortunately, it is too often adopted in busy times—witness a quantity of Cape Heaths in small pots subjected to the drenching of a coarse rose on the spout of a large watering-pot. The job is quickly done, and the operator is off to something else. Perhaps the next batch is pot-bound, and no ordinary amount of water will do any harm; but these receive only the same quantity as the newly-potted ones, and consequently suffer from lack of a sufficient supply.

No. 117.—VOL. IV., NEW SERIES.

This state of things is unfortunately much too common, and the result is that plants of delicate habit succumb to it and die, while disease and a sickly growth follow with others that hold tenaciously to life. Now, the discreet use of the watering-pot is nowhere more required than amongst small or newly-potted plants. Generally speaking, the latter require but little water after being once attended to in that way; while the uneven growth and requirements of small plants alike call for more time and patience in supplying their daily wants than is generally accorded them, and such attention would save many from disease, and in some degree lessen the amount of “death in the pot,” so often referred to elsewhere.

Watering, however, is one of those duties which must be performed at some time or other; and whatever be the evils that arise from it, there is unquestionably much good. Plants grown in pots would not live without water; and where care and circumspection are used the watering-pot is perhaps second to no utensil whatever for its general utility. To use it discreetly, however, can only be learned by practice, or a careful attention to the appearances of the plants to be operated on. With large plants a tap with the knuckles against the side of the pot will enable the daily practitioner to tell by the sound emitted whether they want water or not, but this is too tedious for small plants; besides which, other tokens exist in them sufficient to guide the judgment. A knowledge of the requirements of the plants is also requisite; for some plants require a large supply of water, while others almost exist without it. All these things must, or ought to be, thought of by those wielding the watering-pot; and on the care and prudence by which they administer the daily drink of potted plants much of the success of these depends.

It would be wrong to close these notes without saying something on the description of water to be used for plants. Circumstances often necessitate an improper kind to be used, but when it is possible this ought to be avoided. The kind most suitable for plants is undoubtedly that with which Nature performs the same work—i. e., rain water. This ought not to be contaminated with any foreign substance of an obnoxious kind, which it often is when it remains some time in a tank cemented with some of the cements which give an unusual hardness to the water; neither ought it to remain long in a metallic vessel, that will also in like manner alter its character. Perhaps the best place is a pond or pool, exposed to the full action of the atmosphere, and where it has a chance to be warmed more or less by the sun; next to that is a wooden tub or a stone trough. At all events let the rain water be as pure as possible, and as free as can be from all mineral impurities that it has a chance to acquire in its reservoir. Next to rain water is pond water, if that be good and soft; river water ranks next, and that from wells and springs last.

Occasional mixings of the water with an enriching substance will in many cases be beneficial. But as this is entering upon another subject I will not pursue it further. I would however, again urge all who have the

No. 769.—VOL. XXIX., OLD SERIES.

means of preserving a supply of rain water to avail themselves of the chance, as there is no other water can be so properly used.

Amongst other erroneous opinions respecting the powerful influence of water that are entertained by those who direct its application to plants, are some rather odd notions. A writer to THE JOURNAL OF HORTICULTURE complains that his employer insists that all watering must be done after sunset or before sunrise. This at the time of year I write (June), must give rise to very early and very late hours indeed, but in no case whatever that I am acquainted with is it needed. Certainly a plant perishing for want of water ought to have it without delay whatever the time of day may be, only taking care not to wet the foliage in bright sunshine, or the globules of water left there will form lenses which will burn the plants; and as many small plants must be wetted on the foliage, it is only proper to do it at a time when the fierce rays of the sun are considerably abated, or before they acquire their full strength. When plants are established and seemingly not suffering much from the lack of water, but where they are certain to do so before another day is over, it is best to postpone the watering of such plants until the morning; for as all or most watering cools the ground, and thereby to a certain extent checks vegetation, it is better to delay this until the period when the sun is able to warm it again. When, however, the plant shows evident signs of distress let its wants be supplied at once, for to delay this duty until an established plant absolutely droops or flags is hurtful to that plant, especially if it be a hardwooded one, and Heaths and such plants soon show signs of neglect if treated improperly in the way of water.

In conclusion, it may be added that although the use of the watering-pot may be extended, the desirability of this is far from certain. Nature has endowed most crops with the faculty of enduring such periods of drought as she herself inflicts. Turf may look completely parched up after a period of hot dry weather, and apparently every vestige of life may be gone; but a day or two after a genial rain how it starts into life again! Trees and other large-growing objects are still better able to endure a summer's heat, by sending their roots down deeper or farther off for fresh food, and at the end of a dry season the congratulations of success in certain things quite equal the complaints of the shortcomings of others, where candour allows a fair hearing to all sides of the case. Although the use of the water-pot may be wanted to secure such crops as Lettuce in good condition, Peas on dry ground, Strawberries, and the like, it is more than questionable if one-half the water that is supplied to such crops does not do harm. Watering the ground between the rows so as to induce the fibres of the plants to extend themselves in search of what they want, is both encouraging to their growth and renders them less dependant on hand-feeding. Daily watering to such plants is not commendable, as it only tends to make them root near the surface, and, therefore, become a prey to the first gleam of sunshine that comes on a day they may not have received their usual allowance. Like most other things, plants are accommodating to a certain extent, and if inured to the hardship of trying to make a living for themselves they will do so; otherwise, if they are brought up by hand—i.e., kept as it were by hand-watering, they will trust to that support and become unable to provide for themselves when it is taken suddenly away. All out-door crops ought, therefore, to be watered with caution, and the matter thought of before it is begun, for it is far from certain whether more mischief than good has not arisen from out-door watering. Those, therefore, to whom nature denies the quantity of water to lavishly pour upon ground that it is not unlikely to do harm to, may console themselves that there are many other employments more certainly beneficial than watering often is. J. ROBSON.

THE ROYAL HORTICULTURAL SOCIETY'S EXHIBITION.—JUNE 17.

HEAVY showers on the day preceding this Show gave rise to gloomy forebodings as to the probable character of the weather, and some prognosticated that the Horticultural Society would have "its usual ill-luck." Fortunately, however, these anticipations were not realised, the day having proved highly favourable; and although black clouds occasionally swept over the sky as if betokening the approach of a thunderstorm, the sun shone brightly throughout the day, and no rain fell to mar the pleasure

of the crowds who preferred the open air and the band of the Royal Engineers to the close, heated atmosphere of the Exhibition building.

The fine band of the Marines was posted during the afternoon in the centre of the nave, but though the result fully proved the capabilities of this part of the building in a musical point of view, yet the music was an interruption to the quiet which is desirable for the inspection of plants, besides which it offered a counter-attraction too strong for many.

Although the great height of the building exercised to some extent a dwarfing effect on the plants, this was much less than one would have expected; it must be borne in mind, however, that some of the specimens exhibited were of enormous size.

The Stove and Greenhouse Plants were both numerous and almost without exception large and well grown, though in some instances there was too evident an effort to secure the required shape by means of sticks and tying-in. The species exhibited were mostly the same as those seen at previous shows, and it will be sufficient to mention the names of such as were most remarkable in each collection.

Unquestionably the finest collection of fifteen came from Mr. Whitebread, gardener to H. Colyer, Esq., of Dartford, the specimens being of extraordinary size and in the finest condition. Amongst the most noteworthy were a magnificent *Ixora javanica*, an immense *Erica Cavendishii*, *Pteroma elegans* (a splendid plant), *Rondeletia speciosa*, *Epacris miniata splendens*, *Pimelea mirabilis*, *Vineia alba rosea*, that fine climber *Dipladenia crassinoda*, *Ixora coccinea*, and *Polygala Dalmeisiana*. To this collection a first prize was awarded. The second was given to Mr. Peed for a collection also excellent, in which *Ixora coccinea* and *salicifolia*, *Ericas Cavendishii* and *tricolor flammea*, *Vineia rosea* and *Dracophyllum gracile* were noticeable. Mr. Green was third, having a splendid *Erica obobata*, a fine pyramid *Iveryana Azalea*, *Kalosanthes coccinea*, *Allamanda grandiflora*, and others; whilst Mr. Baxendine, who was fourth, had *Allamanda Schottii* looking very fresh, *Hoya bella*, *Coleonema rubra*, *Aphelaxis humilis rosea*, &c. Mr. Rhodes, who received an extra prize, had a very showy plant of *Erica metuliflora bicolor*.

In the Nurserymen's Class for twelve Mr. Cole, of Worthington, near Manchester, took the lead, most of his plants being very large and fine. We particularly noticed *Aphelaxis macrantha rosea*, *Ixora coccinea* and *alba*, *Epacris miniata splendens*, *Pimelea mirabilis*, and *Phænocoma proliferum Barnesii*. Messrs. J. & J. Fraser were second with a collection in which were noticeable fine specimens of *Prostanthera lasiantha*, *Kalosanthes Angelina*, *Pimelea diosmæfolia*, *Phænocoma proliferum*, and *Boronia serrulata*, the latter, however, being deficient in flowers. Messrs. Lee, of Hammersmith, were third. They had a magnificent *Allamanda Schottii* with immense flowers; a pretty bushy *Leschenaultia formosa*; *Phænocoma proliferum*, also very fine; *Erica Candolleana*, *Clerodendron fallax*, and *Tetradlea verticillata*. Mr. Cutbush, of Barnet, was fourth.

In Class 3, for nine plants, the first prize was taken by Mr. Chilman, in whose collection there were fine plants of *Kalosanthes coccinea*, which is always very showy; *Erica Cavendishii*, fine; *Dipladenia crassinoda*; and *Aphelaxis macrantha rosea* and *spectabilis grandiflora*, both of them excellent. Mr. Page came second; some of the best here were *Allamanda Schottii*, *Dracophyllum gracile*, *Erica tricolor flammea*, and *Pimelea decussata*. Mr. Wheeler, who was third, had among others *Hedera tulpiferum* and *fuchsoides*, *Epacris pulchella*, and *Dracophyllum gracile*. Mr. Kaile received the fourth prize for *Roelia ciliata*, *Kalosanthes coccinea superba*, a large and handsome *Rhynchospermum jasminoides*, and other plants.

Mr. Tegg, gardener to Baron Hambro', Roehampton, had a second prize for a collection of six plants.

Of Fine-foliaged Plants a superb collection was exhibited by Mr. May, gardener to J. P. Butt, Esq., of Arle Court, Cheltenham, consisting of a magnificent *Cycas revoluta*, an enormous *Pandanus utilis*, *Theophrasta imperialis*, and *Jussieu*, *Aralia dactylifolium*, *Croton variegatum* and *pictum*, an immense *Pandanus javanicus variegatus*, and a splendid *Caladium Chantini*. Mr. Smith, of Syon, was second, his collection including fine examples of *Anthurium acule*, *Latania borbonica*, *Calathea zebrina*, *Caladium Chantini*, and *Martinsia caryotefolia*. In the collection from Messrs. Lee, who had the third prize, were fine specimens of *Cibotium princeps*, *Cyathia Smithii*, and *Cordyline indivisa*; and in that from Mr. Hutt, gardener to Miss Burdett Coutts, Highgate, *Philodendron pertusum*, *Latania borbonica*, *Dicksonia antarctica*, and *Pandanus utilis* were the most

remarkable for size. An excellent exhibition was also contributed by Messrs. A. Henderson & Co.

The Orchids, though not so numerous as at the last show, nevertheless afforded an extensive display; the Cattleyas, Vandas, Lælias, and Lycastes, which were exhibited in great numbers, forming a prominent feature, whilst *Ærides* and *Saccolabium* were everywhere seen in abundance. Many of the species and varieties, and, indeed, the very plants had, of course, been already shown at previous exhibitions, and to give a mere list of these would serve no useful purpose, it will, therefore, be sufficient to confine our mention to a few of the most remarkable, and to those not referred to on former occasions.

In the class for twenty, the first prize was taken by Mr. Milford, gardener to E. McMorland, Esq., Haverstock Hill. This was a fine collection, and it included the blue variety of *Vanda Roxburghi*, *Vanda Batemanni*, *Anguloa Clowesii*, *Brassavola Digbyana*, *Cypripedium grandiflorum*, the scarce *Barkeria melanocaulon*, *Lælia purpurata*, *Ærides odoratum* (very fine), *Cattleyas*, &c. Mr. Baker, of Stamford Hill, was second. Among the plants he exhibited were *Oncidium ampliatus majus* and *Cattleya Mossiae*, both very fine; *Ærides Schrederi*, Lobbi, and *odoratum purpurascens*; *Saccolabium guttatum Holfordianum*, and *curvifolium*; also, *Calanthe veratrifolia*, with several fine spikes of flowers. Mr. Page was third, showing among others *Orchis foliosa*, *Maxillaria* sp., *Cattleya superba*, and *Brassia verrucosa*.

In the Nurserymen's Class for twelve there was only one exhibitor—Mr. Woolley, of Cheshunt, who was awarded a second prize. *Lycaste Deppei*, *Camarotis purpurea*, *Ærides Fieldingii*, *Cypripedium Veitchii*, and *Dendrobium Griffithii*, were the most remarkable.

In the Class for ten Orchids, Mr. Penny, Regent's Park, was first with a good *Phalaenopsis grandiflora*, *Orchis foliosa*, *Dendrobium Parishii*, *Ærides Lobbi*, and *Cattleya Mossiae superba*. Mr. Green who was second, had a very fine *Oncidium lanceanum* and *Cyrtocentrum stellatum*; and Mr. Peed was third.

In sixes, Mr. Lovell, of Nutfield, had a fine collection which received the first prize. It contained excellent examples of *Brassia verrucosa*; *Cattleya Mossiae*, a fine mass of bloom; *Saccolabium Blumei* major and *guttatum*, both very fine. Mr. Wiggins, gardener to W. Beck, Esq., Isleworth, was second; and Mr. Whitebread third. *Cypripedium Veitchii*, *Dendrobium densiflorum*, *Vanda tricolor*, and *Ærides odoratum* were the most worthy of mention.

For *Azaleas* the season was too far advanced. Mr. Page had a first prize for *Toilette de Flore*, Gem, Symmetry, Sir Charles Napier, *Eulalie Van Geert*, *Ferella*, *Chelsoni*, and *Striata formosissima*; but they did not nearly approach in beauty the fine plants exhibited at previous shows.

In the Class for six kinds sent out since 1858 Messrs. Ivery and Son had first for *Duc de Brabant*, F. H. Von Waldeck, *Leopold I.*, *Etoile de Gand*, *Striata floribunda*, and *Variegata superba*.

For six *Dracenas* and *Cordylines*, the first prize was awarded to Messrs. Jackson & Son, of Kingston, for fine specimens of *Cordylina heliconifolia*; *Dracena australis*, *Rumphi*, *indivisa*, *terminalis*, and *ferrea*, the latter large and very handsome. The second prize was given to Mr. Bull, of Chelsea for *Dracenas arbores*, *spectabilis*, *australis*, *Draco*, *congesta*, and *Cordylina indivisa*. He had also another collection, consisting of the handsome crimson *D. ferrea variegata*, *Ehrenbergi*, *brasiliensis*, *ferrea*, *fragrans latifolia*, and *australis*.

With regard to *Cape Heaths*, whether it was that some of the plants exhibited had somewhat deteriorated in beauty, or that from having been already seen at previous shows, they had lost some of their freshness, as the eye had become accustomed to them, they seemed scarcely equal to what we have seen before. Still the specimens were very fine, especially those sent by Mr. Peed. These consisted of *tricolor impressa* and *flammea*, *mutabilis*, *eximia superba*, *Massonii*, and *depressa*. Messrs. Jackson & Son, who also excel in the culture of this class of plants, received the second prize for *Bergiana*, *depressa*, *Candolleana*, *ventricosa magnifica*, *tricolor impressa*, and *nobilis*. Mr. Chilman who was third, had *obovata* very fine.

For *Anacothilus* Mr. Bull had the first prize, the kinds being *intermedius*, *Dayii*, *xanthophyllus*, *argyreus*, *Pogonia discolor*, and *Nephelaphyllum pulchrum*.

A multitude of other objects were shown; those coming within the scope of the Fruit and Floral Committees will form the subject of separate reports; whilst florists' flowers and some

other subjects will be taken up by our valued contributor "D." of Deal. There still remain, however, a few exhibitions to notice. Messrs. Ivery & Son had a numerous collection of British Ferns, some of them—as *Athyrium Filix-femina*, *Appelbyanum*, and *glomeratum*, and *Polystichum angulare Elworthii*—being both novel and interesting. *Iveryanum* and *micronatum* are also new and handsome varieties of the first-named species. Messrs. Jackson & Son had *Ouvirandra Berneriana*, a lattice plant differing from the better known *fenestralis*, which was exhibited by Mr. Bull, but much the same in its general aspect. Mr. Bull exhibited *Echites argyrea* (a climber of great promise), the handsome *Begonia Secrétaire Morren*, *Athyrium F. diffusum*, the green-leaved *Aucuba*, and other new Japanese plants, a white-variegated *Juniper*, *Asplenium rachirhizon*, a *Dioscorea* with ornamental foliage, *Marvel* and others of his new strain of *Mimuluses*, together with a fine collection of ornamental-foliaged plants. A collection of eighteen varieties of *Foxglove* came from Messrs. Ivery; *Bougainvillea glabra* from Mr. Turner, of Slough; *Allocasia Lowii* from Messrs. Low and Co.; and *Aralia Sieboldii* and *Cypripedium Stoneii* from Mr. Williams, of Holloway; whilst Mr. Standish had an extensive collection of Japanese plants, of which a variety of *Deutzia crenata* with double flowers—white tinged with pink—was particularly handsome. *Lychnis Senno* was another very ornamental flowering plant, the blooms being scarlet, and as large as a florin. There was also a striped variety, but it was not nearly so pretty. Messrs. E. G. Henderson & Co. exhibited a group of handsome new *Mimuluses*. In cut flowers, Messrs. Barr & Sugden had a great variety of *Irises*; Hooper & Co. hybrid *Ixias*, *Irises*, and *Gladioluses*; Messrs. Butler and McCulloch *Irises*; and Messrs. Fraser, Paul & Son, and Salter, cut *Pæonies* of every shade from white to the deepest red. Lastly, Mr. Whitebread had four magnificent specimen *Ixoras*, the kinds being *salicifolia*, *javanica*, and *coccinea*.

FRUIT.

The show of fruit, though extensive, was not so much so as could have been desired, or, indeed, expected at this season. Black Hamburg Grapes, of which, being the variety most extensively cultivated, we always expect to see numerous exhibitions, were not shown by so many competitors as they generally are, whilst of *Peaches* and *Nectarines* on the other hand there was a superabundance.

The first prize collection came from Mr. Masters, gardener to the Earl of Macclesfield, Tetsworth. It consisted of Black Hamburg Grapes, a *Montserrat Pine*, *Sherburn Castle Hybrid Melon*, *Royal George Peaches*, *Elruge Nectarines*, and a very fine dish of *Empress Eugénie Strawberry*. The second-prize collection was from Mr. A. Henderson, of Trentham, and was composed of Black Hamburg and *Trentham Black Grapes* (both fine), a *Black Jamaica Pine*, *Royal George Peaches*, *Violette Hâtive Nectarines*, and *Trentham Hybrid Melon*. Mr. Turnbull, of Blenheim, had the only remaining collection, in which were three fine bunches of *Muscat of Alexandria*, *Black Hamburg*, an excellent *Queen Pine*, *Royal George Peaches*, and *Sir Charles Napier Strawberries*.

Of *Pine Apples*, the best *Cayenne* came from Mr. Taylor, of Temple Newsam, Leeds; it was a fruit of the Smooth-leaved variety weighing 4 lbs. 14 ozs. The best *Queen*, weight, 4½ lbs., was from Mr. Hutchison, Castle Malgwyn. Mr. Hall, gardener to Earl Scarborough, had one of 5 lbs. 3 ozs.; and Mr. Young, Aberdare, a *Providence* of 12½ lbs.

Of *Black Grapes* the best were from Mr. Lawkins, gardener to G. Brassey, Esq., Bramfield, they being large and finely-coloured bunches of *Black Hamburg*. The second and third prizes were awarded to Mr. Turner, of Slough; and Mr. Jackson, of Tixhall Hall, for the same kind.

In *Muscats* the first prize was taken by Mr. Emberry, of Chadwell Heath, for good-sized bunches, not the largest but the ripest shown, some of the berries becoming of a fine amber colour. To ripen it properly the *Muscat of Alexandria* requires a great heat, and from the generally unripe state in which it is exhibited, it would appear that a sufficient temperature is seldom afforded to it. The second prize went to Mr. Turnbull, of Blenheim; the third to Mr. Turner, the bunches and berries large and fine but too unripe.

In the Any variety Class the first prize was given to Mr. Wills, of Oulton Park, for well-ripened but not large bunches of *Golden Hamburg*; the second going to Mr. Mould, Bushey

Heath, for Chasselas Musqué; and the third to Mr. Cross, for Sweetwater. In the same class Mr. Turner exhibited large but unripe bunches of Golden Hamburg; Mr. Pottle, Buckland Sweetwater; and Mr. Widdowson, Dutch Sweetwater. There was a sad lack of competition in this class, which is one well calculated to give encouragement to and bring out the qualities of new varieties.

Peaches were numerous, and generally very fine. The first prize was awarded to Mr. Rutland, for Noblesse, large and handsome; the second to Mr. Snow, Wrest Park, for Violette Hâtive, remarkably fine; and third prizes to Mr. Allen, of Hopwood Hall, Lancashire, for Royal George, and Mr. Brown, gardener to Sir C. Knightly, for large fruit of the Noblesse. Grosse Mignonne came from Messrs. Boreham, Turner, Cross, and Dawson; Royal George from Messrs. Wills, Turnbull, Cruickshank, and Horwood; and Bellegarde, from Mr. Richards.

Nectarines were also shown in abundance, and some in great perfection. Mr. Rutland had first prize for large and well-ripened Elruge; Mr. Brown was second with Violette Hâtive; and Mr. Horwood third with the same kind. The finest Nectarines shown, however, were those from Mr. Allen, gardener to J. B. Glegg, Esq., of Withington Hall, Cheshire. They were exhibited as the Scarlet, but were to all appearance the Elruge, and wonderfully fine they were, but from being in the Miscellaneous Class they were necessarily passed over without receiving an award.

In Cherries, Mr. Henderson, of Trentham, had first prize for Elton; Mr. Snow was second with Knight's Early Black; and Mr. Enstone third with Elton. Reine Hortense was sent by Mr. Curd, Royal Duke by Mr. Tillery, and May Duke by Messrs. Turner, Ford, Dunn, and Cross.

Strawberries, as exhibited by Mr. Smith, of Twickenham, could not have been surpassed. He was first for a single dish of British Queen, and in three dishes, for the same kind, Empress Eugénie, and Sir Charles Napier, the fruit being of the extraordinary size which he usually exhibits. Mr. Widdowson was second with Sir Harry, and took a similar prize in the Class for three dishes with that kind, Sir C. Napier, and Crimson Queen. Messrs. Turner, Turnbull, and Dwerrihouse, had also excellent exhibitions of Strawberries.

Several handsome Melons were shown. Mr. Terry, gardener to L. Ames, Esq., St. Albans, had the first prize in the Scarlet-fleshed class, and Mr. Meredith, of Garstone, Liverpool, took a similar position for a White-fleshed Hybrid Persian, of very fine flavour.

In the Miscellaneous Class, besides the Nectarines before alluded to, there were several excellent exhibitions of Royal George Peaches, and Violette Hâtive Nectarines, coming from Mr. Allen, of Hopwood Hall, Mr. Horwood, and Mr. Brown; and good Brown Turkey Figs were shown by Mr. Henderson, of Trentham, Mr. Smith, of Syon, and Mr. Cross, the two last-named receiving third and fourth prizes, whilst Messrs. Lane were awarded the first prize for a collection of Apples, Pears, and Cherries in pots, which bore every evidence of health, and were covered with fruit swelling, colouring, and ripe. Messrs. Lee had Cherries in pots; and Strawberries in pots were exhibited by Mr. Horwood and Mr. Cross, the former having Eleanor, the latter Alice Maude and Trollope's Victoria. The fruit of *Passiflora quadrangularis* was also shown, and some well-coloured Tomatoes, as well as a few Apples of last year.

TABLE DECORATIONS AND FLORISTS' FLOWERS.

A wet, cold and damp morning seemed to portend one of the old Chiswick days of the Horticultural Society; but before twelve o'clock the sun shone forth with great brilliancy, and a splendid afternoon attracted a large number of lovers of flowers, lovers of display, and lovers of sight-seeing from all quarters. The Oxford Commemoration detracted, doubtless, from the brilliancy of the fête, by keeping many distinguished persons away; but notwithstanding, the *Dilkoosha*, as a writer in the *Times* facetiously calls it, was crowded with a large assemblage of the upper ten thousand, to witness a very fine display of flowers, and, I believe, fruit; but the latter was so far off from the former, that I for one did not venture on it; and was therefore untempted by what I have no doubt was exceedingly good to look at, but exceedingly sour to the bystanders. The mistake of separating the music *in toto* from the Show was not committed this time, and the presence in the nave of the splendid band of the Royal Marines was a great improvement, attracting a large

number there who thus perforce visited the flowers, who would otherwise have only loitered about the gardens.

The plants and flowers were arranged, as before, down the nave, and filled it from one end to the other. The subjects entered for Sir W. Dilke's prizes were in the southern arcades on entering, while the fruit was in the western arcade. Ample space was thus given for promenading, and the subjects could all be seen to great advantage. As before, however, I think the plants looked dwarfed, owing to the great size of the place, and a temporary awning would have greatly improved it. It is to be hoped that when the Rose Show takes place something will be adopted to protect them from the great heat and glare, or, as I saw in the boxes exhibited to-day, they will not stand much chance.

If imitation be the truest flattery, then assuredly Mr. March ought to feel highly flattered, for nearly all the groups exhibited for Sir Wentworth Dilke's prizes were modifications of his original design; so much so, indeed, that it is a question now, I think, whether we have not had enough of this table decoration. Originality of design there seems to be none; and the differences between the groups are only differences of arrangement. If the thing is attempted again, Sir W. ought to attach one condition—"No birds, beasts, or fishes allowed;" for, with all due deference to the ladies who adjudicated, loves of humming-birds were quite out of all character, and ought, in my opinion, and that of many others whom I heard speaking about it, to have disqualified the exhibitor. They were, too, in such abundance, that the eye involuntarily rested on them, and this, in my opinion, is a proof of incorrectness in taste. The perfection of dressing is when you can say, "How beautifully dressed that lady is!" though neither her bonnet, shawl, nor dress especially attract the eye. So here, too, if the principles were correct which at the first Exhibition made the almost unanimous voice of the multitude second the decision of the Judges in adjudicating to Mr. March and his sister the first prize, because of the simplicity and elegance of the design, then was the decision of to-day quite erroneous.

The prettiest design there was in my opinion Lady Holmesdale's; but this was spoiled by the introduction of some china swans on the plateau. More of this anon—I am in duty bound to take in the order of merit as arranged by the Judges.

The first prize was awarded to Lady Rokeby. This group was founded on the original design of Mr. March, the stand consisting of a plateau, glass rod, and smaller dish on the top. There was a deviation from it in small tubes, which sprang out of the body of the stand, and in which were placed some fronds of light Ferns. Around the base of each stand, instead of the Ferns or Vine leaves recommended and used by Mr. March, there was a wreath of *Cissus discolor*; *Caladium argyrites* for the centre, and *Coleus Verschaffeltii* for the third. The *Caladium*, we think, was a mistake, not being sufficiently in contrast to the white cloth. There were some bunches of Grapes, some of which the humming-birds were supposed to be eating, while others rested on the Fern fronds. It was altogether pretty, but for the reasons I have indicated above it did not stand A1.

Mrs. J. Worthington Bliss, Langton, near Tunbridge Wells, obtained second prize. This, too, was a modification of Mr. March's, some fine fruit being both in the top and stand, with *Stephanotis floribunda* twining up the stem. This in my opinion was superior to Lady Rokeby's.

The third prize was awarded to Mrs. Walter Fawcett, of Westbourne Street, Hyde Park; and it is an evidence that much latitude must be allowed to Judges of matters of taste, when I know that many thought this should have been rewarded with the premier prize.

Those commended were Lady C. Kerrison, whose group consisted almost exclusively of fruit, with a white china centre-piece. Mr. A. Salter, William Street, Hammersmith, had a very pretty set. The top dish was supported, not by a glass rod, but by four light wires, on which, to hide them, were tied some nice fronds of Ferns. Lady Holmesdale had glass ovals instead of a straight glass rod supporting the top, Ferns, Grapes, and some choice Orchids being mixed with them. Mr. Thompson, of 17, Royal Crescent, had a very large plateau into which gold fish were introduced—quite, as I think, out of place, unless it was intended that each guest was to catch his own and have them cooked according to his own fashion. It was, I think, very properly passed over by the Judges. On the whole, my belief is that the original design has never been equalled for simplicity, elegance, and agreement with the principles of correct taste;

and that, as nothing more desirable seems likely to be attempted, it would be well if decoration for some other purpose were encouraged.

It would be impossible, while writing on this branch of the Exhibition, to omit reference to the very beautiful *jardinières*, the invention of Mr. March, which were exhibited in the nave, and bore evidence of the same correctness of taste which has linked his name with table decoration both here and abroad; for it was no little gratification to see on the table of one of the first hotels in Paris, whose *salon* is considered to be hardly excelled for beauty, his stands as forming the decoration. These *jardinières* were glass tables formed of glass of a peculiar character, and white metal—silver or otherwise. The foot was a tripod, holding within it a small dish for flowers; the stem which supported the table of glass, also protected by silver wire, in one case being a succession of knobs, which gave it a very brilliant appearance, while the top was also glass filled with flowers arranged with great taste and judgment. It is impossible to give an accurate description of this very beautiful table, or to convey an idea of the extreme brilliancy of its appearance; but as it will doubtless be exhibited at other shows we would strongly advise all who have large and handsome rooms, and who admire brilliancy of effect without gaudiness, to see for themselves, and we hardly think they will go away without becoming purchasers. The glass was manufactured by the well-known firm of Dobson & Pearce, of St. James's Street.

The Florists' Flowers were especially fine; and although the Council afforded but scant favour to cut flowers, some very beautiful things were placed in that marvellously heterogeneous class—Miscellaneous. Let us hope that next year they may, having learned by experience, do something more for this most popular division. I have only again to repeat that the most crowded parts of the Show were where these were exhibited, while greenhouse plants, &c., were comparatively deserted.

The Pelargoniums were very fine indeed—in fact, such plants as those exhibited by Mr. Nye, Miss Foster's gardener, of Clewer, it is impossible to excel. There was one plant there in his collection—that fine old variety *Sanspareil*, which was a perfect marvel of growth. Others were also fine, but this bore off the palm from all others. His flowers were *Perdita*, *Fairest of the Fair*, *Sanspareil*, *Lord Clyde* (splendid colour), *Desdemona* (beautiful plant), *Rose Celestial* (magnificent both as to plant and quality of bloom), *Ariel*, and *Etna*. Mr. Shrimpton was second with *The Bride*, *Sanspareil*, *Stella*, *Guillaume Severyns*, *Lord Clyde*, *Festus*, *Prince of Prussia*; third to Mr. Page; and an extra (why I know not), went to a collection all sticks and no bloom, which in my humble opinion ought not to have been there at all.

Amongst Nurserymen Mr. Turner and the Messrs. Fraser were the only exhibitors, and in the above order. Mr. Turner's plants were very fine. They were *Prince of Prussia* (somewhat of a dirty look), *Nestor*, *Flora*, *Bacchus*, *Modesty*, *Viola*, *Fairest of the Fair*, *Pizarro*, *Lady Canning* (most lovely), *Lord Clyde*, *Ariel*, and *Beauty of Reading*. Messrs. Fraser were second with *Lightning*, *Guillaume Severyns*, *Lillie*, *Osiris*, *Peacock*, *Monarch*, *Prince of Prussia*, *Etna*, *Sunset*, *Viola*, *Matilda*, *Bacchus*.

In Fancy Pelargoniums the Messrs. Fraser were first with *Roi des Fantaisies*, a bright, showy, but badly shaped flower; *Claudiana*; *Bridesmaid*; *Clara Novello*; *Delicatum*, a nice light, though of indifferent shape; and *Lady Craven*. The second prize was awarded to Mr. Turner for *Clemanthe*, *Claudiana*, *Delicatum*, *Cloth of Silver*, *Evening Star*, and *Roi des Fantaisies*. A very sharp and close race was run in spotted or French kinds between the Messrs. Fraser and Mr. Turner, which the Judges could only settle by giving them equal firsts. Mr. Turner's flowers were Mr. Marnock, a beautiful plant; *Guillaume Severyns*; *Osiris*; *Rembrandt*, bad; *William Bull*, very bright and showy; and *Spotted Gem*, an exquisite plant. Mr. Fraser's were *Madame Furtado*, *Mazepa*, *Sanspareil*, *Bracelet* (good), Mr. Marnock, and *Excelsior* (fine).

It is, we think, unfair upon both Judges and exhibitors to constitute such a class as the best collection of Roses; for one man will interpret that as the best which has the largest number of blooms, and another that which has the best blooms, and hence it generally leads to confusion and disturbance.

As I long ago predicted, when Mr. Turner began Rose-growing, he has become a thorn in the side of some of the older exhibitors, in the present case taking—and deservedly, as I think—first place. Amongst his Roses we noticed *François Lacharme*, very fine; *Catherine Guillot*; *Madame Charles Wood*, very

large; *Général Jacqueminot*; *Anna Alexieff*; *John Waterer*; *Amiral Gravina*, fine dark; *Senateur Vaisse*; *La Brillante*; *Devoniensis*; *Mademoiselle Bonnaire*, good white; *Narcisse*; *Louise Darzins*, best white *Perpetual*; *Madame Boutin*, new and good; *Madame Furtado*; *Comtesse de Chabrilant*; *Madame Boll*; *Vicomte Vigier*; *Paul Ricaut*; *Charles Lawson*, &c. Messrs. Paul & Son and Mr. Mitchell were equal seconds. In the former lot were some few of the new Roses of this year; and, if one may form an opinion, they seem to bear out the conclusion I formed from my visit to Paris last year, that 1863 would not be distinguished for anything very brilliant. *Duc d'Anjou* was pretty; *Madame Helye*, curious shelly flower; and *Deuil de Prince Albert*, good purple; his own *Lord Clyde* was very fine; *Baron Gonella* better than I have ever seen it. In Mr. Mitchell's were some very fine varieties; *Maréchal Vaillant*, good; *Gustave Rousseau*, also good; *Maurice Bernhardt*, fine; *Christian Puttner*, a good dark Rose.

Mr. Turner had a fine box of Pinks, consisting of the following varieties:—*Pride of Colchester*, *Devise*, *Miss Glover*, Mrs. Lamb, *Prince of Wales*, *Titians*, *Constance*, *Victory*, *Cristabel*, *Dr. Maclean*, *Lord Elcho*, *Princess of Wales*, *Samson*, *Diadem*, *Lizzy*, Mrs. Turner, *Minnie*, *Nina*, *Blondin*, *Kentish Volunteer*, and some seedlings. The lacing of these was very beautiful, and the individual flowers were large.

Of other cut flowers there was a very pretty collection of *Ixias*, *Sparaxis* and other allied bulbs, amongst which *I. viridiflora*, *crocata*, and *crateroides* were noticed as being very pretty. This is a class of flowers that must become popular. Messrs. Downie & Co. exhibited thirty-six Show and thirty-six Fancy Pansies; also their excellent bedding *Calceolaria Cloth of Gold*, and the new *Delphinium bicolor grandiflorum*. Mr. Turner had a fine box of *Verbenas*, containing, amongst others, fine blooms of *Lord Leigh*, *Lord Craven*, *Firefly*, *Fairy*, *L'Avenir de Bellant*, &c.

Two very fine collections of exotic Ferns were exhibited—the best by Mr. W. Bull, the second by Messrs. A. Henderson. Mr. Bull's contained magnificent plants of *Cibotium princeps*, *Cyathea dealbata*, *Cibotium culcita* and *Barometz*, *Gleichenia flabellata* and *dichotoma*, *Alsophila radens* and *excelsa*, *Marattia elegans*, *Dicksonia antarctica*, and *Davallia dissecta*. Messrs. A. Henderson had *Drynaria muscifolia*, *Gymnogramma calomelanos*, *Cibotium Barometz*, *Adiantum tenerum*, *Lastrea patens*, *Cyathea boconensis*, *Phlebodium pulvinatum*, *Cibotium Schiedeii*, *Alsophila australis*, *Angiopteris evecta*, *Drynaria coronans*, and *Brainea insignis*.

Messrs. Ivery had a beautiful collection of British Ferns, comprising *Asplenium adiantum nigrum acutum*, *fontanum Halleri*, *septentrionale*, *trichomanes*, *trichomanes ramosum*; *Athyrium Filix-femina*, *F. f. conoides*, *crispum*, *diffusum*, *Fieldiae*, *Iveryanum*, *multiceps*, *mucronatum*, *plumosum*; *Blechnum spicatum* *polydactylon*, *ramosum*; *Ceterach officinarum*; *Cystopteris fragilis regia*; *Lastrea lepidotha*, *Filix-mas cristata*, *pumila*; *Osmunda regalis cristata*; *Polypodium phegopteris*, *Robertianum*, *vulgare cambricum*; *Polystichum foliosum*, *angulare varians*, *Wollastonii*; *Scolopendrium vulgare crispum*, *endiviatifolium*, *marginatum*, and *sculpturatum*.

Amongst the new flowers exhibited was a large quantity of seedling Geraniums, but very inferior both in number and quality to those exhibited last season. There were two very fine flowers of Mr. Hoyle's—*Achilles*, a magnificent high-coloured *Beauty-of-Reading* style of flower, of perfect shape, and with a beautifully clear white throat; and *Artist*, already noticed. There were also *Gloxinias*, *Mimuluses*, bedding *Geraniums*, &c., which will, doubtless, appear in your report of the Floral Committee's proceedings. Nor can I omit the very beautiful double *Deutzia* sent by Mr. Standish, another of the valuable contributions from Japan, and as a hardy shrub most valuable for our gardens.—D., Deal.

UNJUSTIFIABLE EXCLUSION OF GARDENERS FROM AN EXHIBITION.

I BEG to forward the schedule issued by the Royal Belfast Botanic and Horticultural Company. The rules laid down for the admission of gardeners have caused very great dissatisfaction amongst the exhibitors and gardeners in general, as they consider themselves grossly insulted in being invited to send their productions to the Show to be held on the 27th August, but are not to be admitted to the place of exhibition themselves except

for a short time to see what prizes they have taken, and for half an hour before the Show closes.

The gardeners have held a meeting, at which it was resolved, and the resolution signed by fifty-four gardeners, that if they, the exhibitors, were not to be admitted at a reasonable time after the public, they would not on any account send their productions to the Show. Are the exhibitors asking more than they have a right to expect from the above Company? The gardeners of Belfast and neighbourhood will feel greatly obliged if the Editors will please to give their opinion on this subject.—N. T. Y., *Belfast*.

[To apply to the rule for such an exclusion of gardeners the mildest term it deserves we reprobate it as very unreasonable. At the London exhibitions gardeners are admitted at all times during which the public are admitted, and at such exhibitions gardeners certainly have as fellow-spectators members of the community as high in position as they will have at Belfast. So far from submitting, as the Belfast gardeners seem willing to submit, to be admitted "a reasonable time after the public," we advise them not to submit to be admitted a second later than any one else. They will have too much good sense, as have their brethren elsewhere, to inconvenience any one; and, moreover, their presence is desirable, and we know of more than one member of the aristocracy who delights in seeing and obtaining information from gardeners at such gatherings.—EDS. J. OF H.]

BHOTAN RHODODENDRONS—AMARYLLIS CULTURE.

I HAVE been anxiously expecting intelligence from Mr. Cox, of Redleaf, respecting "the yellow-looking, smooth flower-bud," exhibited by a Bhotan Rhododendron under his care. Have the buds expanded, and what are the blossoms like? Is it hardy, and where can it be purchased? I have heard of one this year producing white funnel-shaped flowers, with a deep orange-coloured centre, and most deliciously fragrant.

As to the Amaryllis and its varieties—I have read with much interest Mr. Anderson's paper respecting this beautiful bulb, and I am surprised that it is not more generally cultivated. I have a fair collection, and flower them well with very little trouble. When I first commenced their cultivation I had only a few, but possessed a roomy hot pit, in which they grew and bloomed vigorously, enabling me to make my drawing-room gay during the dreariest days in winter. At my present residence I have only a large greenhouse, with Melon-frames. In the autumn and winter the dormant roots are stored away under the flue, and kept there till my bedding Geraniums can be removed from a deep pit, which is then filled with tan, and the pots of Amaryllis, about one hundred in number, are plunged in the fermenting material, and in about a few weeks come into bloom, and become beautiful ornaments in my conservatory. The warmth of the greenhouse enables them to mature their foliage and ripen their roots. Many of my bulbs are seedlings of my own, and though they might not "pass muster before the Floral Committee," are really beautiful decorative objects. The list of varieties given by Mr. Anderson in No. 113 is very tempting, and it would be a kindness to me, and, perhaps, to many others, if he would say where they are to be purchased.—A DEVONIAN.

HEATING GARDEN STRUCTURES.

(Concluded from page 436.)

THE small Arnott boiler will heat 100 feet of four-inch pipe, consume less fuel than any boiler known, and require less attendance than most.

Small boilers, however, consume more fuel proportionately than larger, and take nearly the same quantity as a flue; and the first cost of one being nearly double that of the other, persons ask themselves, "What is the good of having a boiler when I can get a flue for half the money?" If you measure the growth of plants by their cost, and can see goodness in cheapness, and derive more pleasure from badly-grown plants than from those well grown, by all means keep to flues.

A clever man may do as much with a flue as a bungler with a boiler; but give a clever man a boiler, and where is your flue? Gone for ever. If an amateur's experience is limited to flues, how can he form an opinion of heating by hot water? I feel

sure that many amateurs keep to flues for economy; but were they in a position to have a boiler, I have no doubt which they would prefer. I also grant that some may have a house heated by a flue doing good service, even better than his neighbour's boiler; but how much more indomitable perseverance is possessed by one than the other? More depends on a patient dogged perseverance than on the merits of a system, and on a knowledge of details than all the fine theories possessed without application. Diligent attention and the application of a few matters will do more to insure success in cultivation than all the learned ologies, as Mr. Fish puts it, with carelessness and no application.

Mr. Robson must take a similar view, for he wishes to heat a house by hot water, which is strange considering that he pronounces hot air as good for vegetation as hot water. Why does he want hot water for a house to be kept at a high temperature, when he writes flues are as good? It appears to me as if he was desirous of taking the opinion of others on this question, and makes a few extreme remarks in order to provoke a discussion. The call has been only moderately responded to, and I hope all of us will contribute our mite, and if we do, I am sure the fate of flues will be sealed for ever.

Though "E." prides himself in being able to heat a house 110 feet long with a flue for less money by half than the cost of a hot-water apparatus, I will not say that he cannot; but I do say he cannot keep the frost out of such a house unless he has a blasting-furnace and a flue like a town sewer, and that he would burn more coal in a month than will afford ample to last a boiler a twelvemonth. I cannot see how he would heat the house with one flue at all; but he, no doubt, has a novel plan of his own as rare and as simple as the one so lately given in this Journal. "E." will, perhaps, tell us the quantity of space he calculates a superficial foot of flue to heat, how hot a flue will be after it has travelled 20 yards, to say nothing of 50, and whether he could not roast a ham in the chimney after all. I have known a flue fire traverse 30 yards of bricks and mortar, and though the flue was not warmer than an adjoining wall, the heat in the chimney was more than the hand could bear. Soot in a flue, 3 inches or more thick, forms a barrier against the absorbing powers of brick and prevents the flue heating, as any housewife knows her oven heats badly unless it be clear of soot. As "E." is so confident of his wondrous flue-knowledge, I invite his attention to an estimate for heating a house for a vinery 110 feet long, 20 feet wide, 5 feet high at sides, the roof a span at an angle of 45°.

	£	s.	d.
Boiler	12	0	0
Sliding doors, &c.	2	2	0
Fire-bricks, ship, or fire-clay, common bricks, and mortar	0	15	0
Boiler-setting and chimney-building, mason and labourer, four days, including firehole, digging and walling round	1	8	0
520 feet of four-inch pipe, or 4 tons 4 cwt., at 5s. per cwt.	21	0	0
Bends, elbows, &c., 4 cwt., at 11s. per cwt.	2	4	0
Fixing pipes, with materials.	6	10	0
	45	19	0

This would contain 22,000 cubic feet, and 148 feet of heating surface at a temperature of 212° would be required to heat it and keep the temperature at 62° steadily; but having also 3880 feet of glass, or cooling surface, four times that quantity of heating surface will be required to secure a temperature of 55° in all weathers, and six times a philosopher's calculation to maintain a temperature of 60°.

"E." will be so good as give his estimate, for according to my notions he would want four flues and as many fires to obtain the same heat and a result below par. The boiler would consume a ton of coke fortnightly for four or six months according to the season and the time the fruit is desired to be ripe, which at 6s. per ton is £3; but his flues would consume a ton a-week of small coal in all weathers (for flues do not burn coke well), two in severe, which at 7s. 9d. per ton, would give 20 tons, £7 15s., being £4 15s. in favour of the boiler, with one-quarter the trouble and attention; and whilst a gardener could leave his boiler and house in perfect security at 6 P.M. in mild weather, and at 8 P.M. in severe weather, "E." would have to stoker hard every three or four hours, and go to bed late with a conviction in his mind that he must be up early, long before nature is awake. Thus the boiler would save £4 15s. annually, which in seven years amounts to £33 5s., during which time the boiler would not cost 6d. beyond 3s. 6d. in cleaning out once a-year, whilst "E.'s" flues would cost at least 7s. 6d. in sweeping and washing with lime water, to say nothing of repairs, and at ten years' end the boiler would have saved its first cost by consuming so little fuel. The pipes would

be as good as ever, the boiler last another ten years, and the owner would not be pestered with hydrogen smells, nor see his Vines drooping and scorched with fire-damp and a crazy flue, after wasting £47 or more, enough to build the owner a moderate-sized greenhouse.

We had a boiler put in in 1835, and though old and worn it was not useless when it was removed to make way for a larger, and the pipes were as good as ever—they had never cost a penny in repairs, and they did not need any after twenty-seven years wear and tear, neither can they be distinguished from new pipes. I mention this boiler and pipes in justification of my statement, for some people have an idea that boilers are soon worn out.

In heating a number of houses hot water is without an equal; but having given the cost of heating five houses by flues I will heat them with hot water by way of comparison.

The range is 180 feet by 18, all of them kept at a high temperature; costing for heating with flues £47 10s., and £26 10s. in fuel annually.

	£	s.	d.
Boiler	20	0	0
Doors and frame	3	3	0
1400 feet of four-inch pipe, four pipes in front, two at back, and two along each end	70	0	0
Branches, elbows, syphons, connections, and valves	24	0	0
Boiler-setting, preparing-for, materials, chimney-building, &c.	4	3	6
Pipes, fixing with materials	27	0	0
	£148	6	6

We have the sheds heated by the connection-pipes, plants in some, Mushrooms in others, potting-shed as nice as possible, and all arranged so that one can be heated at once or them all, separately or together; and a couple of pipes run under the tanpits so as to keep the beds warm. All this is done with the fuel of one fire, saving annually the fuel of eight fires, and doing the work as well again, without blowing-up anything or robbing ourselves of sleep, of which it is said, "Six hours is enough for a man, seven for a woman, eight for a fool;" but I recommend the fool's portion for every one. Also by carrying the connecting-pipes along the sheds you will do away with bothies. That is worth more than all the good hot water ever did; for I estimate inventions nothing unless they give less manual labour, and are more economical, and conducive to health and comfort. Bothies are repositories for weary limbs, cause unhealthiness, breed disease and demoralisation, and are altogether unfit for human habitations. The sooner under-gardeners are driven out of them, and a comfortable house provided with a thorough draught in an open situation, the better it will accord with the objects by which they are surrounded, and the more conducive will it be to the owner's interests and the inmates' social and moral advancement.

Owing to our saving the fuel of eight fires we nett £21 4s. yearly, which will in seven years amount to £148 8s., thereby clearing the cost of the apparatus in that period; but with a crazy set of flues the real expense attending them is only fairly beginning.

Now, coals may make a difference—that is, their cost, in speaking of the relative merits and defects of flues and hot water. Where a range of houses is heated by flues and fuel is cheap—say 2s. 6d. per ton, it may not be wise to take out the flues and replace with a hot-water apparatus; it may not be more economical, but it will be better and far more garden-like. A man upholding flues appears to me to be similar to a thrasher contending there is nothing like a flail to thrash corn—he had rather do the work of a horse or a steam-engine than allow his mind to move with the age.

Just one point more and I have done for the present. "Where the houses are wide apart, it is more economical and satisfactory to heat them with flues than hot water." In a case like that the boiler works at a disadvantage, heating a greater length of pipe outside the house than within. But with that drawback I contend hot water is the cheapest and best in the long run; for instead of using four-inch flues we use 1½-inch wrought-iron pipes, and the same for returns—that is, all the connections are 1½-inch, costing 6½d. per foot, increasing the heating powers of the boiler one-third, promoting a quicker circulation, and giving a very satisfactory result. We have six houses heated on this principle; and instead of employing 1200 feet of four-inch piping we have but 800, the remainder are 1½-inch; so that we have a boiler with little work, and capable of putting limbs on to plants where we have flues taking them off by wholesale.

I hope to see the flues brought down to their proper level, the rubbish-heap, soon; and by using 1½-inch connection-pipes to heat more houses, than can be done in the ordinary way. I may say the work is done better by 1½-inch connections than with four-inch.—G. A.

HARDY PALM.

CULTURE OF CYANOPHYLLUM MAGNIFICUM.

Will you tell me the name of the Palm which stood out last winter at Kew? It is very much like the *Latania borbonica*. I was round there in October, and all the Palms were then taken in except this one.

What height does the *Cyanophyllum magnificum* usually attain in its native clime? I grew one here 11 feet high, having leaves 26 inches long and 13 inches broad. The stem was 2 inches in diameter. I never saw one so fine before, and so said all visitors. It is cut down now, and a very nice walking-stick made with the stem. If you think it was unusually fine, I could tell you how it was grown, as it had a peculiar treatment.—A YOUNG GARDENER.

[The Palm you mention is Fortune's *Chusan Palm*, *Chamaerops Fortunei* of Hooker, formerly called *C. excelsa* in English gardens. At Kew it requires the protection of a mat in severe weather; but in Her Majesty's garden at Osborne it has hitherto stood unprotected.

Certainly we never saw *Cyanophyllum magnificum* so lofty as you mention, nor the leaves so large. These are usually about 24 inches by 9 at the broadest part. We shall be obliged by a statement of your mode of culture.—EDS. J. OF H.]

LILIUM GIGANTEUM CULTURE—DISA GRANDIFLORA.

HAVING been successful in growing the *Lilium giganteum*, the culture which I have followed might be useful to many of the readers of THE JOURNAL OF HORTICULTURE.

I have had this season two bulbs in a fourteen-inch pot, each of which has sent up a flower-stem 10 feet high. One stem had thirteen flowers and the other twelve, and beautifully sweet-scented.

The growth was commenced the first week in February in a cold pit, no heat applied at any time—merely protection from frost. The soil I used was one-half the top spit of a meadow well pulverised, the other half peat and sand well mixed together. When fairly in growth I gave water in abundance, and liquid manure, not strong, about twice a-week. I believe that if the pot had stood in water about an inch or so above the drainage in the pot it would have been more beneficial to the plant, for, this being of quick growth and gigantic stature, requires water in abundance.

I have a plant of *Disa grandiflora*, a sucker from one which was sent here from M. Schiller, of Hamburg, last April twelve-month. It is now nearly 12 inches high, and it seems to be forming a head at the top. Do you think it is likely to flower? As I have not seen any other *Disa* I am at a loss to know. The plant is healthy and growing fast. If it should bloom I will, if acceptable, send you a few lines as to how I have proceeded with its culture.—J. EASTWOOD, Gardener to E. Nathan, Esq., Didsbury Lodge, Manchester.

[We think the *Disa* is progressing properly. We shall be obliged by particulars of its culture.—EDS. J. OF H.]

NEW BOOK.]

The In-door Gardener. By Miss Maling. London: Longman and Co.

WE regret to see by this title-page that Miss Maling again has changed her publisher. This is the fourth or fifth time within about twelve months, and such deficiency of permanency is usually indicative of an author being either unpleasant to co-operate with, or that his works are not profitable; or, as in some instances, that these disagreeables have a combined influence in causing such changes. If the other productions of Miss Maling have had a small sale, for the present volume we cannot

anticipate a better success; and were it not on a popular subject we should not occupy our space, even briefly, by uttering a word of warning concerning its contents.

Miss Maling, like many other ladies, has a great love for flowers, combined with excellent taste in arranging them; and she has frequently published in various forms her judgments upon such arrangements; but now that she offers to instruct in flower-culture, we regret to have to warn our readers she must not be accepted as a teacher. The practical cultural portions of the present volume are chiefly derived from other sources, our own columns amongst the rest, though in our case Miss Maling does not seem to acknowledge the justice of the axiom, that what is worth borrowing is worth acknowledging. We might complain, also, if it were worth while, that each page, contrary to all custom, is headed "In-door Gardening," the name of one of our publications, although the title of Miss Maling's work is "The In-door Gardener."

As the first qualification required by a teacher is correctness,

we should advise a page of corrigenda to be inserted, in case the volume should not reach to a second edition, for there are no such names among plants as *Gneorum*—*Chautini*—*Lycopodium apoda-cesium*, &c. Such errors, however, with the exception of repeated *Dennstatia*, may be typographical, but there are others more weighty. For instance, *Loam* is defined as "any fertile growing soil, not exclusively formed of some one material like peat, or clay, or sand, or leaf mould," which is such a tissue of error ill-expressed, as would require more time to explain than we are willing to bestow.

Again, who ever heard before that "many gardeners never use soil which has not been charred or frozen?" or that "scales are chiefly appendages of *Camellias*?" Or—but we can occupy our space no further; and will only add that we shall be glad to see Miss Maling again in print when she has some more novelties to communicate on the combination of colours and arrangement of flowers; for on those topics she is an authority.

STYLIDIUM AMÆNUM.

THIS introduction to our gardens from the Swan River colony, has been raised by Messrs. Henderson & Co., of the Pine Apple Nursery, and was, we believe, collected by Mr. Drummond, who sent over so many of the fine plants of that country which now ornament our greenhouses and conservatories. The *Stylidium amœnum*, without the gaiety of many New Holland shrubs, is decidedly pretty, and must be a desirable addition to this class of plants. It blooms in June. The *Stylidium nudum* of Lindley is now considered to be synonymous.

It is a herb—perennial, we believe—having at the surface of the soil a rosulate tuft of leaves, which are spatulate, $2\frac{1}{2}$ to 3 inches long, tapering to the base, shortly acute at the apex, and terminating in an apiculus; they are paler on the lower than on the upper surface, and have a broken cellular hyaline, scarcely denticulate, margin; when fresh they are scattered with transparent dots; the veins are dichotomous, scarcely anastomosing. From the centre of this tuft rises the erect scape, 6 inches high, terminating in the upper half in a pyramidal many-flowered raceme, below which is a whorl of linear-pointed bracts. The rachis, pedicels, and calyx are furnished with hairs tipped by black glands. The flowers are large, rose-coloured, measuring five-eighths of an inch in diameter. The pedicels are shorter than the calyx, subtended by small lance-shaped bracteoles. The calyx, besides its gland-tipped hairs, is marked with red dots and streaks; its teeth are linear-oblong obtuse, those of the lower lip three in number, narrower than the two forming the upper lip, all being shorter than the ovary. The

corolla is three times as long as the calyx-teeth; the upper lip consists of four oblong blunt, spreading lobes, the lower is very small, with a gland-like deltoid prominence at the base; a pair of short lateral ears, or projections, which become very indistinct in the dried state, and a subulate petal-like point; the throat is furnished with a crown of six clavate processes. The column is flattened at the base, becomes tapered upwards, and is bent twice in the usual way.

The *Stylidiids* should be grown in sandy soil with a preponderance of peat earth, and require to be very carefully drained, for though they like a good supply of water while growing, they cannot endure stagnant moisture. A warm, dry, and airy greenhouse is the best situation for them. Many of them are very pretty, indeed showy plants; and, in all, the structure of the flower, and the irritability of its column, are so curious, that they have good claim to the small space they occupy.—(M., in *Garden Companion*.)

TANNER'S BARK FOR STRAWBERRY-BEDS.

ALLOW me to relate in corroboration of a statement made by a gentleman to Mr. Fish (see page 422), concerning the use of tanner's bark for surrounding Strawberries when fruiting, that I happened to visit the Viceregal gardens the other day, and when passing along a walk with Mr. Smith I observed his men throwing wet fresh bark between the lines of Strawberries. I inquired, "Will it not give an unpleasant flavour to the fruit?" "Not in the least," he replied; "I have used it for

that purpose for several years. The first shower," he added, "washes the tannin and finer particles down. Slugs, too," he remarked, "do not like to travel amongst it, and I much prefer it to anything else that I have tried."

It has just struck me that where cocoa-nut fibre can be obtained at a reasonable price it would be an excellent thing for the same purpose.—D. PRESSLY, *Knockmaroon, near Dublin.*

THE ROYAL HORTICULTURAL SOCIETY.

Is Sir C. W. Dilke authorised to represent the Council of the Royal Horticultural Society, and do the rest of its members do too to him? I ask this because of the following circumstance, for the correctness of which I appeal to the parties mentioned:—

Previously to the issuing of the schedules of prizes this year, I hear that Sir C. W. Dilke solicited an interview with Mr. Marnock at Kensington, to which Mr. Marnock replied that if Sir Charles wished to see him he would be happy to receive him at the Regent's Park. I hear also that the interview took place, and that Sir Charles then proposed that they should arrange to cut down the prizes offered exactly one-half, making twenty-pound prizes £10; ten, £5, and so on; that Sir Charles considered that the Crystal Palace was a commercial concern, and not to be taken notice of, although I believe, in some circuitous way, the same reduction was suggested to Mr. Bowley. I hear further that Mr. Marnock, with a correct sense of what is for the interests of the Society and is due to the exhibitors, told Sir Charles that he would certainly bring the proposal before the Council of the Royal Botanic Society, but that he entirely differed from him, and that he thought some of the classes had prizes not large enough; and so the interview ended.

Now, I ask, is not this just the sort of proceeding that destroyed the Royal Horticultural Society before? Or did the Council sanction the proposition, and authorise Sir Charles to arrange, if he could, a reduction of prizes?—AN INQUIRER.

[We have no relative information on the subject; but we do know that if the Council of any Society allows one of its members to become dictator, no one fitting to belong to that Council will remain. It is equally certain that if the Council of any society enrolled for the promotion of an art or science, and, finding its expenditure excessive, begins retrenchment by diminishing its outlay on legitimate objects, and yet continues its outlay on objects not within its charter, that Council are derelict of duty, and pursue a course which sooner or later will be the Society's ruin.

There certainly are rumours afloat that the expenditure on the Kensington and Chiswick Gardens is to be very largely reduced, and if so, that is not the direction towards which one would have thought a horticultural society would have directed its economy. But having no specific information we refrain from commentary.—EDS. J. OF H.]

THE FLORAL DECORATIONS AT THE CIVIC ENTERTAINMENT.

THE gorgeous display of flowers that adorned the Guildhall on the occasion of the civic entertainment to their Royal Highnesses the Prince and Princess of Wales, was furnished, we understand, by Mr. B. S. Williams, of Holloway. It is but due to Mr. Williams that the fact should be recorded, for we have been asked on many occasions since who it was to whom the credit was due of having supplied so admirable a collection of plants. On application to Mr. Williams we have been furnished with a list of the plants of which the collection was composed; and those acquainted with their beauty and value will at once be enabled to form some conception of the effect that was produced.

ORCHIDS.—*Vanda suavis*, 5 feet high, tricolor, insignis; *Saccolabium guttatum*; *Ærides Larpentæ*, affine, odoratum purpureum; *Cattleya Mossiæ*, *Warnerii*; *Lælia purpurata*; *Phalanopsis grandiflora*, *amabilis*; *Cypripedium Veitchi*, *barbatum superbum*; *Calanthe masuca*.

FERNS.—*Dicksonia antarctica*; *Alsophila australis* in the most luxuriant health, *aculeata*, *radens*; *Gleichenia dicarpa*, *heciostophylla*; *Cibotium Schiedei*, *princeps*; *Cyathea elegans*; *Adiantums*, a number of kinds, among them were the Gold variety lately introduced; *Gymnogrammas*, the Gold and Silver, also the tasselled sulphur variety.

FINE-FOLLAGED PLANTS.—*Chamærops excelsa*, *Cordylina in-*

divisa, *Dracæna indivisa*, *Cyanophyllum magnificum*, *Alocasia metallica*, *A. Lowii*, *Cycas revoluta* (splendid specimen), *Dion edule* (magnificent plant, 14 feet through), *Dracæna Draco Børhavei* (the finest in the country, very rare), *Rhopala corcovadensis*, *R. magnifica*, *Stadmannia Jonghii*, *Theophrasta imperialis*, *Tupidanthus calypttratus*, *Agave filifera*, *Yucca aloifolia variegata*, *Pandanus elegantissimus*, *P. javanicus*, *Thrinax elegans*, *Aralia Sieboldii variegata*, *Ananassa sativa variegata* (several fine specimens), *Azaleas* (fine specimens), *Cheloni*, *Exquisite*, *Gledstanesii*, *Glory of Sunning Hill*, *Juliana*, *Extraneæ*, *Eulalie Van Geert*, *Gledstanesii formosa*, *Lateritia*; a monster *Erica Cavendishii* in a large tub. Specimen *Roses*, &c., were kindly lent for the occasion by Mr. W. Paul of the nurseries, Waltham Cross.

Mr. Williams had also the honour of having supplied the bouquet for Her Royal Highness the Princess of Wales.

ADMITTING AIR NEAR SMOKY TOWNS.

ON reading a lady's inquiries on the above subject I thought a little of my own experience would not be out of place in the Journal. I am close to a large town which contains about forty thousand inhabitants. On the east of me there is nothing but factories and houses, and only the breadth of two fields in front; on the west and north I am free from both, but have *Ashton Moss*, which a short time ago was a swamp. There are two large cotton mills within 300 yards of my place, and they have not much less than 300-horse power of engines, with the requisite number of boilers, giving me more smoke than I can well reconcile myself to.

I have, therefore, adopted the following plan to prevent the smoke from passing into the houses. Over the ventilators I have put a screen made of Shaw's tiffany, and find that it "riddles" the soot from the air as the latter passes through—that is, the air in reality passes through a sieve. I find that it answers very well, for the tiffany is made as black as soot in a short time, the soot adhering to it instead of going into the house. As soon as my hands are not so much employed as at present I shall have a little more to say on airing in smoky places.—JOHN HAGUE, *Groby Lodge, Ashton-under-Lyne.*

ROYAL HORTICULTURAL SOCIETY.

JUNE 17TH.

FLORAL COMMITTEE.—At the second great Exhibition, this day, the subjects brought before the Sub-Committees were of a very interesting character. The new plants on this occasion were more numerous than the florists' flowers, and though many beautiful specimens of the latter were exhibited, but few received awards. We shall notice them as they presented themselves.

Mr. Mills introduced a new bedding *Verbena*, *Othello*, a dark puce or claret, dwarf habit, compact trusses, and very free-flowering. This is likely to prove a very useful bedding variety, and was commended.

Mr. E. J. Lowe sent a very good stand of seedling *Pansies*. Among them a promising *Fancy* variety, *Pallas*, violet back petals, dark eye on yellow ground, lower petal very dark, singularly belted with violet. This will probably become a useful flower. Commended.

Messrs. Smith, Dulwich, had a seedling *Fuchsia*, *Pillar of Gold*, a distinct golden variegated form of this plant, and was commended for its foliage.

Mr. Williams, Holloway, had *Amaryllis Perfecta marginata*, a distinct and good variety of the numerous seedlings of this class. Its form and peculiar white markings or stripes on a dull red ground rendered the flower attractive, and was awarded a first-class certificate.

Mr. Hally, Blackheath, sent *Pelargonium Adonis*, a zonal which had been grown in 1862 in the gardens at Chiswick, where it was much admired and classed among the best varieties for its beautiful darkly-zoned foliage, bright orange scarlet flowers, and conspicuous white eye. It now received a first-class certificate.

Messrs. E. G. Henderson, had a collection of hybrid *Mimulus* of the same character and colour as those exhibited by Mr. Bull earlier in the season. Commended.

Mr. Turner exhibited *Petunia* Mrs. Sherbrook, a fine decorative variety resembling Mrs. Ferguson, but of the large pentangular form of the old variety *Prince Albert*. Should the

flowers prove constant in their colour and markings, it will be very useful. Commended.

Mr. Watson, St. Albans, showed *Calceolaria Bijou*, a decided acquisition among the dark bedding varieties; dark rich crimson flowers, dwarf habit, and free-flowering. Second-class certificate.

Mr. Bragg, Slough, had a collection of seedling Fancy Pansies. Though late in the season for this flower, the three varieties—Bob Ridley, Harlequin, and Dazzle—received a label of commendation.

Mr. Turner sent several seedling *Pelargoniums*. *Achilles* (Hoyle), a very splendid and brilliant flower, back petals deep maroon, margined with bright carmine, clear white centre, lower petals painted with rosy crimson, first-class certificate; *Pelargonium Aristides* (Hoyle), dark back petals, white centre, lower petals shaded with light rosy lines—though a small flower, perfect in form and substance, second-class certificate; *Pelargonium Maid of Honour* (Beck), an improvement on *Viola*; rather too coarse, but distinct in shading of colour, commended.

Among the plants submitted to the Sub-Committee we noticed the following:—

Mr. Standish, Ascot, *Deutzia crenata rubra*, from Japan, a double variety of this beautiful class of very handsome shrubs, said to be hardy, and which will, doubtless, be much sought after—first-class certificate.

Messrs. Veitch exhibited *Rhynchospermum jasminoides variegatum*, commended; *Homœanthus viscosus*, with double light blue flowers resembling the Cape Aster, commended; *Lastrea erythrosora*, a very handsome Fern, second-class certificate; *Woodwardia japonica*, a Fern already exhibited by Mr. Standish, but never in such good condition, second-class certificate; *Andromeda* species, California, a very conspicuous shrub with erect spikes of white flowers showing themselves above the dark green box-like foliage, commended; *Pancratium* species, from Philippine Islands, with large heads of white flowers, a very showy plant, first-class certificate; *Lomaria* species, from the Philippine Islands, commended; *Alsophila Tanitis denticulata*, a very handsome Fern, second-class certificate; *Selliguea pothifolia*, a Fern from the Philippine Islands, second-class certificate; *Marattia Cooperi*, first-class certificate; *Pinanga*, species nova, Philippine Islands, commended.

Messrs. Fisher, Holmes & Co., exhibited *Abies* species, North America, which was commended; and *Taxus fastigiata*, with golden-coloured shoots, first-class certificate; *Cypripedium Stonei*, from Mr. Williams, of Holloway, received a first-class certificate.

Mr. Bull had *Cineraria argentea*, which may prove useful as a plant for edging, commended; *Trichomanes crispum rufum*, a very distinct variety with long, narrow fronds, second-class certificate.

FRUIT COMMITTEE.—Two seedling Pines of considerable merit came from Mr. Stevenson, gardener to the Earl of Durham at Lambton Castle, but neither of them was superior to existing varieties. Mr. Thomson, of Dalkeith, sent a splendid bunch of his seedling Grape *Duchess of Buccleuch*, which received a first-class certificate.

HAS THE CLIMATE OF ENGLAND CHANGED?

THE opinion upon this question given by me a few years ago in *THE COTTAGE GARDENER* entirely agrees with the remarks of the *Mark Lane Express*, quoted in *THE JOURNAL OF HORTICULTURE* of June 9th; and while endorsing all that is advanced in that excellent agricultural adviser I will add a few additional remarks deduced from experience, having kept a table of the temperature since 1805.

The vulgar error that the climate has undergone a great alteration during this present century is owing to our severe winters and very hot summers coming so few and far between.

A middle-aged man recollects the severe winter of 1813–14, when the snow lay on the ground in England for thirteen weeks, and 1838 was equally severe; the only difference was the fall of snow. The most intense cold in the present century was the winter of 1859–60, when the thermometer was 7° below zero several days, and yet the young people keep saying that our winters are much milder and summers much colder.

If these persons would take the trouble to examine the oldest and best chronologies and registers of the seasons contained in Mr. White's "History of Selbourne," Mr. Whistecroft's writ-

ings, and almanacs, it would be found that in a term of thirty years at any time during the last hundred years there is no perceptible difference in our climate whatever; we are now going through a series of indifferent or medium seasons after a series of much better seasons—such as 1854, 1855, 1856, 1857, 1858, 1859, the last three remarkable for the mildness of their previous winters and the intense heat of their summers, particularly the whole of July, 1859.

Through our insular situation in England no regular theory can be established; and from long experience I find the best guide, and that a very uncertain one, is the history of the summers gone by, as, in a cycle of forty years, the balances of cold and hot summers, severe and open winters, wet and dry seasons, become pretty nearly equalised in that period.

I have noted during the present century that by far the majority of the hottest summers are preceded by the mildest winters; and agree with that excellent naturalist, Mr. White, of Selbourne, that the majority of severe winters are preceded by wet summers.

I have also noted that we seldom have two very severe winters consecutively, nor two "ultra" hot summers; respecting wet summers, often two wet ones come together, but rarely three so wet as 1860, 1861, and 1862 consecutively.

I shall merely repeat my strong conviction that no change has taken place in the climate of England during the present century, save and except those variations arising from the peculiar insular situation of the British Isles, which extraordinary variations always have existed and will continue to the end of time.—H. W. NEWMAN, *Hillside, Cheltenham*.

ANNUAL REPOTTING OF FRUIT TREES.

IN No. 114 of *Journal*, your correspondent, "W. H.," gives the practice of his gardener in the annual repotting of his fruit trees. From longer experience than that of any other orchard-house cultivator, I with confidence state that this troublesome practice is quite unnecessary. To prove this I will in few words give my practice. In 1849 I potted the first orchard-house trees in 11-inch pots, they remained in those pots from four to five years, the earth from the surface being annually taken out to the depth of 4 or 5 inches, and replaced with a rich compost of loam and manure. The trees flourished and bore fine crops of fruit.

They were then repotted into 13-inch pots, in which they remained from four to five years under the same treatment. The most vigorous-growing trees were then potted into 15 and 18-inch pots still under the same treatment—the latter size I reckon the ultimatum, for I can plainly see that with annual top-dressings and annual pinching and pruning, they will continue in health and fertility as long as human wishes can extend.

Your correspondent's failure in Apricot-culture may be traced to the too great disturbance of their roots. Some years since I, from forgetfulness and ignorance of the consequences, had my Apricot trees, then in full bearing, top-dressed in February, taking out the surface soil and replacing it as I now do in autumn. The trees blossomed beautifully, but to my great surprise did not set a fruit. I was much chagrined, and for some time could not account for it, till at last I reflected that the roots being thus recently disturbed had not got into action; the young fruit required food and found none. I have ever since profited by the lesson, and my Apricot trees are the first to be top-dressed in October.

Apricot trees in pots require the soil to be very firm. The failures I have observed have been owing to the soil used being too light and friable, and not rammed down firmly enough when placed in the pots as top-dressing. The soil used here is a brown tenacious loam inclining to clay, which, like all the loams and even the sands in this district, abounds in comminuted chalk, the washings or denudation of what once were, I presume, chalk mountains to the north-west of this place. This loam settles down so firmly in the pots that in the autumn it is as hard as a well-trodden path. To show the favourable nature of a firm dry soil to Apricot trees in pots, I must give a case. Last winter I observed some forty or fifty standard and half-standard trees, which were potted in March, 1862, to have small heads scarcely large enough for sale, but every shoot full of blossom-buds. They had been under glass all the summer. I had water withheld from them till towards the end of February, when the blossom-buds were beginning to swell, so that the earth, not having had any water for nearly five months, was remarkably hard and dry as dust.

Shortly after water had been given at intervals of a day or two so as to gradually saturate the mass of dry earth, the buds commenced to swell, and the trees blossomed in April most vigorously. In May, as soon as the fruit was fully set and about the size of horse beans, the surface of the soil in the pots was stirred and removed to barely 1 inch in depth, taking care not to lacerate the surface-roots. The usual summer surface-dressing was then placed on the surface of the earth in each pot 3 inches or so deep, so as to lie above the rim of the pot and forming a shallow basin with the stem of the tree for its centre. This prevents the water running off. Out of about fifty Apricot trees treated as I have described, upwards of forty are crowded with fruit. It seemed, indeed, as if every blossom had set, so that the thinning of the fruit was tiresome.

The requisites for successful Apricot-cultivation in pots are, according to my experience—1, a firm tenacious soil disturbed annually as little as possible, for in giving my trees their fresh surface soil in October, the exhausted soil is not taken out more than from 2 to 3 inches in depth; whereas with other trees from 5 to 6 inches is not too deep; 2, rich surface-dressings in spring and summer—say three separate dressings in May, June, and July, the first week in each month.

The value of these surface-dressings can scarcely be estimated, they are far preferable to liquid manure. I have tried all the artificial manures mixed with different substances so as to form a proper medium for surface-dressing, and have come to the conclusion that none of them approach in efficacy that which can be made at home—viz., horse-droppings from the roads, or half-decomposed manure chopped so as to be equally convenient in mixing, and kiln-dust from the maltings, equal quantities, the mixture thoroughly saturated with strong liquid manure before it is used. Care must be taken not to lay it in a large heap, for fermentation is so violent as to injure the compost. In default of kiln-dust (here our atmosphere is eminently malty and our people, I fear, too beery, from the number of malthouses), the manure or horse-droppings may be used without the dust, only they should be well saturated with strong manure water.

I have been induced to trouble you with this long array of words on a very simple subject, because I saw that your correspondent's gardener, as described in page 399, might lead your numerous readers to think the annual repotting of fruit trees necessary, and others to look at their culture with "fear and trembling." Just imagine the labour of annually repotting a well-grown fruit tree from eight to twelve years old: one might as well think of annually retubbing the Orange trees at Versailles. As I have advanced certain facts, I must make myself responsible, I therefore give you my name.—THOS. RIVERS.

A PLEA FOR THE BIRDS.

I HAVE two neighbours—one, like myself, a true lover and guardian of the feathered race, feeding, sheltering, and welcoming them at all seasons, and not allowing any which build their nests in our gardens to be disturbed. The other gentleman shoots and destroys them with equal pertinacity; and thus whilst his Gooseberry bushes have not a leaf left on them, ours are in full foliage; our little feathered "helps" destroying the caterpillars as soon as they make their appearance.—A. Z.

[Some months ago I wrote my opinions on this subject. The topic occasioned some controversy at the time. A correspondent from Worcester, whose communications on other subjects I have read with great interest, agreed with me, that in general these tiny garden helpers or garden pests, as they are alternately called, are much too numerous. Some provincial papers I found also took the matter up, and, as might be expected, considerable difference of opinion existed. I may, however, observe that in the neighbourhood in which I write, where plantations of Apples, Currants, Gooseberries, &c., cover many hundreds of acres, the benefit of small birds destroying caterpillars is far from being generally recognised. An extensive grower who owns something like a score acres or more of Gooseberries, and who, of course, has at times suffered severely from the caterpillar, told me not long ago, that he has shot birds of all kinds that are to be generally found in such places, and he never discovered a caterpillar in the crop of any he had cut up. As the caterpillars are often as destructive in cottage gardens situated close to a wood where there is abundance of shelter for birds, and from whence these issue forth in scores to attack the Peas, seed-beds, fruit, &c., it is far from certain yet that the birds destroy

caterpillars, or, if so, it may only be when there is a lack of other and more agreeable food. Observe, I by no means say they do not eat caterpillars; but as I never saw them do so, although I have seen them busy enough with other things, it is not asking anything unreasonable to request those who have done so to inform us what kinds we are to regard as friends in this matter. In giving opinions of this kind, we ought to lay aside our predilections for or against the object in view, which is more difficult to do than most will acknowledge. That small birds play an important and useful part in the economy of nature cannot be denied; but do not wasps, snakes, rats, and other things also form a useful part of the whole? and yet we are very unwilling to give them credit for anything but mischief or destruction. I am not certain but that the last-named of the three are the best sanitary agents we have, cleaning away the refuse of drains and sewers, that might be pestilential without them, and yet they are persecuted to the verge of annihilation. As I gave my opinion at length at the time mentioned, I have little to add now beyond the fact, that although I have never yet seen birds pick off caterpillars from Gooseberry bushes, I am willing to believe they have done so, but would like better to be told by some one who had seen them, than take it for granted that as the caterpillars all disappear at a certain time, it must be the birds that have devoured them. If a discussion arise on this subject, I would take the place of a neutral. Give evidence in favour of the little warblers, I cannot; to condemn them on the plea of their non-utility, I am unwilling, if evidence be forthcoming that they really do destroy the enemy complained of; but such evidence to be received ought to be that of an eyewitness, not the opinion of an advocate. Without this proof, I fear I must hold by the opinion expressed in my former article—that, owing to the reasons there given, small birds are much too numerous at the present day.—J. ROBSON.]

CATERPILLARS—THE BEST WAY TO DESTROY THEM.

My object in writing to you is to make known to the lovers of the Gooseberry the method I have this year adopted for, I trust, effectually overcoming the enemy. It is founded on the maxim of old Ovid, who was an acute observer of nature as well as a distinguished poet.

"Principiis obsta. Sero medicina paratur
Cum mala per longas convalere moras;"

which I translate for the benefit of mere English readers—"Meet the very beginnings; medicine (Hellebore, &c.), is provided too late when the disease has gained strength by long delay."

But first let me describe how the caterpillars get upon the bushes. I have observed two kinds—first, a light green one, which is counted by units, while another, also green but dotted over with numerous black spots, is counted by hundreds. The latter is the production of a small fly, which may be seen flying about the bushes in the first warm days of May—that is the time hereabouts, but it may be earlier in the south. This fly is the *Nematus grossulariæ*, and belongs to the order of insects which have four membranous wings, named Hymenoptera, and to that class of them called Tenthredinetsæ, or Saw-flies, from the female possessing a saw-like ovipositor in the end of the abdomen. With this she makes a series of small holes along the veins on the under side of the leaves of the Gooseberry and Currant, into each of which an egg is discharged, and along with it a drop of frothy liquid, which covers it up. The punctures thus made become more and more convex as the eggs increase in size, and on turning up the leaves, they may be seen like strings of small white beads; generally from twenty to fifty eggs are deposited on one leaf. This is the first of the four stages of metamorphosis which all insects of this kind undergo. The next is that of the larva or caterpillar. In a few days, according to the warmth of the weather, the eggs are hatched, and the juveniles immediately begin to gnaw the leaves; the period of their rivification is known by a series of small holes seen on the upper side of the leaf as if pierced with a pin. At first they keep together on the leaf on which they were hatched; but when that is devoured all to the veins, they creep upwards to the adjoining leaves, and finally spread over the whole bush, quickly increasing in size, for they are very voracious. After a while they moult, or shed their skins several times, and then crawl down and hide themselves in the earth. There they attain the third state of their existence, called a pupa or babe,

because it is bound up in a hard skin, somewhat resembling a child trussed up like a mummy, according to the barbarous fashion once prevalent in this country, and still retained in many parts of the world. In some insects the pupa assumes a golden colour, and is, therefore, called a chrysalis. In this third state the animal remains till the following spring. It eats no food, is incapable of locomotion, and, if opened, appears filled with a watery fluid, in which no organs can be traced; but that gradually assumes consistency, and on the approach of the vernal heat, the enclosed insect, now completely formed, bursts its case, and enters on its fourth and last stage called imago, being a true representative or image of its species.

I shall now describe my process of extermination. In former years I had tried several modes, especially handpicking; but not having begun till the caterpillars were spreading over the bushes, I never could completely destroy them. This year, being resolved to attack the enemy in their first entrenchments, I had been carefully watching their approach from the beginning of May, when the weather suddenly grew warmer, the greatest heat in the shade on April 30th being 58°, and on the next two days 69°. It was not, however, till the afternoon of Saturday the 23rd that I discovered on some of the bushes a few perforated leaves. The fly, guided by its natural instinct to seek a sheltered abode for its future offspring, almost invariably deposits its eggs on the lower leaves of the bushes. Some have supposed that if in pruning them you cut away all the low shoots there will be no caterpillars. This is a mistake; for if the bushes have no leaves near the ground the flies will go higher up, still keeping to the lowermost. In those bushes which are clothed with leaves from the ground I have hardly ever seen any eggs above one-third up.

There are seventy-two Gooseberry bushes in my garden. Having secured two lady volunteers to assist me in the attack, I allotted to each of them one-fourth of the number, and took the other two under my own charge. We commenced operations on Monday the 25th of May. By a careful reconnoitring it is easy to discover the haunts of the enemy in the perforated leaves where the newly-hatched animals have commenced their work. Wherever such leaf is found the operator will by turning up a few of the adjacent leaves, almost invariably find three or four of them covered on the under side with the bead-like eggs, all the produce, doubtless, of one fly. All these should be plucked off into a small flower-pot or other vessel, and afterwards carefully burned. I recommend plucking off on bushes which are thickly clothed with leaves, as tending to give more air and light to the fruit; but on bushes which are thinly clad, it may be preferable to retain the leaves and squeeze the eggs with the thumb. On the first two days I destroyed in my department, on a fair calculation, about 10,000 of the enemy, which gave on an average, about 280 to each bush. Had these incipient larvæ and eggs been allowed to come to maturity (for almost every egg will come into life), they would within a week or so have spread over the bushes, and if molested, would soon have devoured the leaves. By timely vigilance this has been prevented. But it must not be supposed the work was done; for all the pupæ do not burst their covering at once, and therefore the flies continue the work of depositing for a short time, though in smaller numbers than at first. Allowing an interval of one day, I examined the bushes again, and found a few stray leaves with the young vermin or eggs on them, and every second day I have picked a few; but it is an easy work now to keep them under, as they have never been allowed to enlarge in size or migrate from their original positions except in a very few cases. This day (June 4th) I did not find on an average above two leaves on each bush that required excision. The labour is therefore now very small; in fact, a sort of recreation to any lover of gardening; but it must be kept up for a short time longer—that is, till all the flies are hatched, which will probably be in about a fortnight. This mode of destroying the caterpillars is, in my opinion, far preferable to washing or sprinkling with hellebore or any other substance; for it is more effectual in destroying the enemy, and less injurious to the bushes. Though hellebore—now the fashionable remedy—may kill or stupefy the animals, it is impossible to apply it to every leaf, and a good many will be devoured after all, which will injure the quality of the fruit; whereas by my method of picking off or bruising the eggs and infantile larvæ, no material damage is done to the bushes. All mine look as healthy and fresh as if there had not been a tenthred in existence.

Before concluding, one word on the destruction of those

little animals which are so injurious to our Roses, the *Aphis roseæ*, commonly called "green fly," but more properly plant lice, for they are apterous or without wings. They infest the tender shoots, and multiply very rapidly. Tobacco juice and tobacco smoke are used for destroying them; but the most effectual mode, I think, is that which I have practised for some years. An assistant holds a small basin or deep plate with some water in it under the infested shoot. I hold that steadily in a horizontal position over the water with one hand, and with the other brush the aphides into it with an old shaving-brush. This takes a little time, but is very effectual.—J. T., *Coupar-Angus*.

THE COTONEASTER MICROPHYLLA.

THE accommodating nature of some plants, and their adaptability to ornament, in widely different situations and positions, render them to a certain extent very great favourites for this distinctive character. And I believe the *Cotoneaster microphylla* in this respect will bear a favourable comparison with almost any plant in common use, although, when left to itself, it only develops a very uninviting, straggling, and careless habit, more or less recumbent, and is as if of no importance; but when seen under the hand of the skilful and accomplished cultivator, many varied and endless contrivances have rendered many an insignificant plant, when brought under cultivation, objects of great adaptability, useful, and ornamental beauty. The *Cotoneaster microphylla* may well be classed among the plants which cultivation has rendered both useful and ornamental; by way of illustration I will just notice a few of the situations which I have seen this slender and helpless-like plant occupying, and worthily filling as an ornamental plant. I have seen it planted on steep declivities, growing and rambling about there, upon and amongst rocks and large stones, and keeping such situations from becoming bare and naked during a large portion of the year, while all deciduous plants appear more or less like mere skeletons of what they are in summer; its dark foliage and bright berries giving a pleasing relief in the dullest season. On the bank or rockery in the home grounds of an estate occupying some sheltered nook or rock fernery, this plant, from its recumbent habit, is most suitable and useful, as it will grow pretty well under a good deal of shade. I have seen it overhanging bare rocks for 6 or 7 yards, where perhaps scarcely anything else would grow downwards. I have seen it occupying the outside corners of the walls of gardens, where it made a very creditable appearance, being nailed firmly against the wall, and there standing the "battle and the breeze" far better than almost any other plant which I know, and perhaps for this reason, that its hardy habit and very small leaves render it very difficult for even a regular north-eastern wind to lacerate or take off.

I know some cottages where it is very neatly trained all up their front, and that too in rather exposed situations. I know two cottages occupied by labouring men; they are built with a very rough rubbly stone; they consist, as is often the case in England, of four rooms each; two on the ground floor, and two bedrooms each, between the doors is planted a *Cotoneaster microphylla*, which runs up and very nearly covers all the front of both these cottages, after passing over the door of each. Many admire it—they stand close to the side of a road much frequented, and many give them a pleasing look and much admire this plant, both while in flower, and especially during the dull winter months, while it remains studded all over with its reddish berries.

I know an entrance lodge to a gentleman's residence, situated in a narrow glen, amongst plantations by the roadside. It is a thatched cottage, having a projecting porch or doorway entrance. A plant of the *Cotoneaster microphylla* grows against this porchway and quite overtops it, rambling all over it, at least it is not kept neatly nailed in, as in the case of the two cottages; only whenever any strong branch appears to get the mastery, or grows too much away from the building, then this is cut away. I think I never saw anything more appropriate for such a situation. Those acquainted with its habits will soon understand its merits for ornamenting the front of a cottage in entrance to a drive through a plantation.

The last, which I will at present notice, is not one to be recommended; however, from its oddity I will just mention it. A greenhouse standing in the pleasure ground of a suburban residence, which I know very well, has at one end a plant of this *Cotoneaster* planted against it, and trained along against the

side of the front beam where the roof starts from, and at each rafter a branch of the Cotoneaster is trained up upon the rafter between the lights. Whether so training plants be recommended or not, I will not say; yet few plants are more suitable even for such fancy work than this Cotoneaster is.—(G. DAWSON, in *Scottish Gardener*.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE late heavy rains have done invaluable service in this department. Crops that a short time ago were languishing for want of moisture are refreshed, and have an appearance which, as contrasted with that which they bore some time back, is quite delightful. *Broccoli*, let there be no delay in getting out a good breadth of White and Purple Cape and Grange's Early White, which, if true, is invaluable in late autumn. *Cauliflowers*, some of the late sowings to be planted out. Break down a few leaves over the heads of the most forward. *Cucumbers*, the plants on the ridges will be benefited by being mulched with short grass or litter of any kind. *Endive*, a full sowing may now be made for the main crop; and if any were sown in May they had better be thinned-out, and the thinnings transplanted. The Small Green-curbed is the hardest for winter use; but for the autumn crop the Large Green-curbed is the best, planted in very rich soil at 2 feet apart. The large-leaved Batavian is also a useful variety. Where *Chicory* is in request for salads now is the proper time to sow it. *Dwarf Kidney Beans*, thin and earth-up, stop advancing crops, and sow the latest successional crops. *Herbs*, take the first opportunity as soon as they are sufficiently advanced to cut a portion for drying; the best time is as soon as the blossoms are expanded, because they then contain most of the aromatic principle; to be cut when perfectly dry, and to be dried quickly in the shade. *Lettuce*, tie-up for blanching, and make successional sowings; the same of Radishes and other salads. *Scarlet Runners*, make the last sowing, and give those advancing a little assistance in training them up the stakes. *Vegetable Marrows*, mulch as recommended for Cucumbers; peg-down the bines as they advance, and attend to stopping. Trench-up and fill with Broccoli, Winter Greens, and such kinds of crops, every space as the early crops go off; not one vacant space or corner should now be left uncropped.

FLOWER GARDEN.

The weather has of late been all that could be desired, and the rain has fallen so copiously as to put a stop, for a time at least, to the laborious operation of watering. Plants in masses that have been pegged-down are growing rapidly, and the Verbenas are throwing-out strong healthy roots from the stem, thus showing the advantage of the system of pegging-down, as the closer we can get all plants in masses to the surface of the ground the more certain shall we be of success; for from their proximity to the soil a more robust and rapid growth is secured. Advantage should be taken of the present showery weather to fill up all the empty beds, also to plant-out German Asters, Ten-week Stocks, Marigolds, and other annuals, to fill up all the empty spaces in the flower-borders. Reduce occasionally some of the blossoms in the bud state on some of the very free-flowering Perpetual Roses. It will cause them to keep longer in bloom. Let gross shoots on Fancy Roses be pinched when a few eyes long, after the manner of fruit trees. Sow Brompton and Queen Stocks for spring-flowering, selecting for them a bit of light rich soil, and never letting the surface become dry until the plants are well above ground, for there is no time to be lost if these are wanted strong for blooming next May. Young shoots of Pansies will root freely under a hand-glass in a shady situation, and if planted-out in a rich soil in a shady corner will grow rapidly during the autumn, and may be transplanted into the flower-garden when the frost cuts off its present occupants. See that sufficiently strong stakes are applied to plants with heavy foliage and gross habits—such as Dahlias, Hollyhocks, Larkspurs, Phloxes, and tall-growing Asters. Let Carnations and Picotees be layered as soon as the shoots are in a proper state for that purpose. Pinks may be piped or struck from cuttings. There is little art in this operation, as, if kept moderately moist in a shady situation, they will soon strike root.

FRUIT GARDEN.

The season being now what is called a very growing one, there is a necessity for increased diligence in keeping all young wood properly nailed to the walls to guard against the effects

of high winds. Gooseberries and Currants trained against north walls to have their leaders nailed-in, and all the side offshoots spurred-in to within a few joints of the base. Peaches, Nectarines, and, indeed, wall trees in general, will be greatly benefited by occasionally giving them strong syringings, whether infested with aphides or not, because, independent of washing away all filth, this proceeding disturbs and drives-out woodlice, earwigs, and other vermin. Continue the thinning of Grapes, and keep the growth judiciously stopped. Black fly is sometimes very troublesome on the late Cherry trees at this season; it is, however, easily got rid of by dipping the ends of the shoots in tobacco water, giving the trees a good washing with the engine next morning.

GREENHOUSE AND CONSERVATORY.

Give every possible attention to plants for autumn and early-winter blooming, as *Lilium lancifolium*, *Chrysanthemums*, *Salvia splendens*, *Globe Amaranths*, tree Carnations, *Scarlet Geraniums*, *Heliotropes*, *Cinerarias*, &c. Let them have plenty of pot-room, good rich compost, a moist atmosphere, and plenty of space for the perfect development of their foliage. The *Epacris*, the winter-blooming *Ericas*, and the *Cytisus* should not be overlooked. Most of the finer kinds of hardwooded plants will now be out of bloom, and, consequently, due attention should be paid to starting them for another season. Some will require cutting-in rather closely, and, indeed, as long straggling plants are at a discount now, the knife should be used freely wherever and on whatever it is found necessary. See that large specimens of *Camellias* are not allowed to be too dry at the root after they have set their buds, for the shedding of the latter is often due to this cause. Attention to be paid to plants in borders, for while in active growth they require a good deal of water. Contributions from the stove should still assist the ordinary stock in maintaining the gaiety of the conservatory. The removal of some of the larger specimens from the stove, such as large *Clerodendrons*, *Ixoras*, *Stephanotis*, *Plumbagos*, *Gardenias*, *Jasminums*, &c., will afford much useful space for the young and delicate portion of the stock which should now be shifted and otherwise encouraged.

STOVE.

Many of the basket Orchids will soon be protruding their roots through the moss or soil, and a little additional fibrous peat or moss should be added in due time. The prevailing dull weather will render the use of the syringe less frequently necessary. Atmospheric humidity may be sustained by frequently damping the house. If the regular and continuous admission of air can be managed, however small the amount, it will be found useful.

PITS AND FRAMES.

These will require abundance of air and careful watering daily. Some of the delicate stock will, during bright sunshine, require shading, especially where unplunged. W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

STAKED Peas in dry days. Gave manure-waterings to large Cauliflowers. Threw some salt among Asparagus-beds, and will give some mulching as soon as we can get it. Removed all seed-heads from Sea-kale, except what will be wanted for seed. Mulched Globe Artichokes, these being much in demand. Thinned Onions, Parsnips, and Carrots finally for the main crops. Find the Early Dutch Carrot useful for early work, as it comes in so well for dishes and stews. It is a little round thing about 1½ inch long, and now in a slight hotbed pretty well 1 inch in diameter, and from a yard square numerous dishes can be obtained, if there is little thinning, and the best are drawn first. Peas being very heavily loaded, owing, we presume, to the dry, sunny weather before the rain, gave them a watering at the bottom with weak manure water. Planted-out strong plants of Celery, three rows in a bed, in beds previously used for hardening-off bedding plants. On the ridges between such beds, in general, we have a row of moderately early Peas, and they with their sticks just give the shade that the Celery at an early period likes as naturally as a ditch plant. We could not have the Peas there on account of the necessity of walking on the ridges to attend to the bedding plants; but we have sown late Peas there, and even the staking of them will break the force of the sun's rays; in the meantime, if the sun should be very fierce, we will lay pea-stakes across the beds to diminish its force.

We consider this slight shade of much importance to early Celery, and if among the sticks used for Pea-sticking, or for laying across the beds, there should be a portion of spruce fir, there will be less likelihood of the fly meddling with the plants. We find the same thing with Turnips. Our sowings are always small until the autumn, as small, sweet tubers, rather than old and large ones, are our object; and in every fresh sowing of a few yards square, if we cover with hurdles that have been watled with spruce, we seldom suffer either from birds or fly. The resin in the fir seems very hateful to them. Here we may mention that we saw a large piece of ground sown with Radishes in the garden of a gentleman farmer, and scarcely a plant was to be seen, and did not the seedsman catch it behind his back for sending such seed. The birds knew what the seed was and acted accordingly. If, surrounded with large thatch buildings, we had sown Radishes without any protection, we should not have expected to have gathered a handful. Planted out the only little spare piece of ground with equal portions of Scotch Cabbaging Kale, Savoys, and Brussels Sprouts. Planted others between Potatoes, and pricked-out more in beds, to be lifted as space could be had for them, as the Peas come off. Examined Mushroom-beds, spawned a fresh piece, regulated Cucumbers, potted Capsicums, &c.; and as a mild hotbed in which we had forwarded Celery and bedding plants, and consisting chiefly of leaves, was now empty, had it turned over, placing grass and litter at the bottom, so as to throw in a little fresh heat, put soil over all, and planted with Cucumbers and Vegetable Marrows, so that if they do well they may run over the beds, and beyond them. Even for pickles we find a little bottom heat does them good.

FRUIT GARDEN.

Went over wall trees, thinning and shortening shoots. Will do so with standard Apples, Pears, and Cherries, as soon as possible. Strawberries, first watered, and then rained upon, are doing well, and coming in to succeed the last of those in orchard-house. Watered borders in the latter heavily with weak manure water, and looked after insects. Removed out of doors a few Cherry trees from which the fruit had been gathered. Watered Figs again which are planted shallow in a house, as it is hardly possible to make them too wet when the fruit is swelling, provided the moisture is not stagnant. Watered Peach-house also heavily with soot water, the fruit coming in a few at a time on the front trellis, whilst those on the back wall are still like bullets. Thinned and regulated Grapes. Those in small early pit have been most useful and abundant—pit 6 feet wide, bed for Vines about 3½ feet, hot water below and above. The plants are in the bed, and have borne too heavily for years. We have some fear that some of them have got out of the little bed, and if so, the success will not be so continuous. These have chiefly borne on the young wood. In three lights of Sweet-water, there were from fifty to sixty fair-sized bunches. Melons ripening in frames have had a little water given to the bottom through holes, leaving the surface dry. Pines will want a little shading in bright days, after dull ones, if at all near the glass. If kept cool, about 60° to 65° at night, they will stand a high temperature during the day—say from 80° to 95°, if a little air is given early.

ORNAMENTAL DEPARTMENT.

The pits being now more at liberty, from plants going out to the flower garden, have potted into larger pots varieties of Coleus, Begonias, Gesneras, &c., and given them a little bottom-heat; also Balsams, Achimenes, &c. Potted Ferns, dipped Stanhopeas in manure water, as they were getting rather dry, and the flower-buds were coming strong. Potted-off Achimenes, Gloxinias, &c., and kept them at first in the shade, with air, as the least condensed moisture on the leaves when the sun strikes the house will do them harm, and spot and mark them. Potted Geraniums for succession, Fuchsias, &c., and also Chrysanthemums for large specimens. For want of a better place, clustered most of the Azaleas at one end of the conservatory, where we can keep them closer, and give them plenty of the syringe, neither of which would answer Pelargoniums, Fuchsias, &c. We do not expect these to be so forward as those placed in a house where they can have as much moisture and heat as is necessary. The last time we saw such a house of Azaleas, belonging to one of our princes of nurserymen, every plant was glistening with moisture, as if they were covered with dew-drops; the hot-water pipes were in reality hot, and the plants were breaking and growing in a close, moist atmosphere at a temperature of from 80° to 90°. Such plants duly hardened-off by more air and less moisture,

and more sun as the shoots were made, and then still more hardened-off by greater exposure, would just be in a position for forming, resting, and then swelling and opening their flower-buds, as soon as the excitement of warmth and moisture was given to them. Such sweet plants as the Gardenias, that have been blooming in an intermediate-house, such as a warm greenhouse, just require similar treatment after pruning and cleaning, only if they should have the advantage of a mild, sweet dung-bed, or a sweet tan-bed, with a bottom-heat not above 85°, they will like it all the better than mere hot-water moist heat. Free-growing, and free-blooming Heaths, as Wilmoreana, hyemalis, linnaeoides, &c., will delight, after pruning and resting for a week, with just less moisture in the atmosphere, and less heat than the Azaleas, and more air must be admitted as soon as the young shoots are formed, or there will be danger of drawing and of mildew. Epacris will now rejoice if fairly started into growth in a cool pit, where they can be slightly shaded in bright sunshine. But as they grow more air must be given, and for part of August, and through September and October, the less obstruction that is offered to direct sunshine, the better will the wood be studded with flower-buds. All hardwooded plants after flowering require a little of these same conditions—resting, after pruning for a week or two, then a closer and a moister atmosphere to cause fresh growth, and a drier and sunny atmosphere to consolidate growth. This latter remark refers to Gompholobiums, Leschenaultias, Pimeleas, Polygalas, and New Holland hardwooded plants in general.

In growing all these plants, a slight dewing of water from the syringe, morning and afternoon, and even in the middle of the day, does more good than deluging with waterings at the roots, or even flooding the floors of the house. Many a hardwooded plant is sent to its last home from excessive waterings at the roots, when the plant is in that comparatively dormant state that the roots cannot absorb much nourishment, and, consequently, if there is the least derangement in the drainage, there can be little result but paralysis and decay. In all such cases, after trimming, and before fresh growth commences, the roots should not be dry, but they should be dry rather than wet. A slight sprinkling among the stems, and a rather close atmosphere for a few weeks, will cause the fresh growth to come away more kindly than if the roots were saturated, and when the shoots are an inch or two long, is the best time to repot or top-dress, &c., according as may be required.

For all such plants good drainage is indispensable, and freedom from worms if the plants stand on the floor of a pit, or out of doors. Even a few rough ashes are almost an equal requisite to success. This is still more important if the plant is to be plunged partly or wholly in a hotbed. Then, all precautions to the contrary, there will most likely be a few worms, and these will pass in by every opening in the plunged part of the pot however small. For all such plants that have thus to be plunged, as respects their pots, or set upon the ground, or rough ashes, we prefer pots with one good hole in the bottom to those with numbers of holes, greater and smaller in size. Then a very simple means will secure good drainage, and defy the entrance of our otherwise good friends the worms. The best means of securing this would be little convex caps of a mixture of zinc and copper to place over the holes, which with the weight above them would be so close to the pot as to let water out and yet prevent a small worm entering, and that they would soon give up attempting, as their sleek sides would receive something like a galvanic shock every time they tried it. A much simpler mode is at hand on every potting-bench, if people could be persuaded to use it. We say persuaded, for if you give ever so plain directions on the subject, you will have the pleasure in turning pots up to find that the directions have been more attended to in the breach than the observance. This simple mode is just placing a suitable-sized piece of broken pot with its convex side downwards, and so as to cover the hole completely, and from one-quarter to one-half inch on each side of it. This will be as secure a barrier to the worm as the zinc cap. "Oh!" but says our potter, "it will get choked up with earth and prevent drainage." And so it would, just as any one piece of drainage in a pot in which the plant was to continue any time. But we by no means mean to confine our drainage to this one convex piece of crock with its rounded side downwards. Upon this we lay other pieces not quite so large, with their rounded side upwards, forming so many bridges over the first crock, and extending the process close to the sides of the pot. Upon these goes another layer of smaller pieces, and then a thin layer of smaller pieces

still, or washed pebbles or gravel, mostly from the size of beans to that of early peas, and over that again we place a layer of clean moss to prevent the earth above washing into the drainage, which it will be effectual in doing, if worms are prevented from entering and making a quagmire of the whole contents of the pot. This thorough drainage will be more secured if the compost of soil is open and has some pebbles and pieces of charcoal mixed with it. Remember, however, that open rough material for compost, and making the roughness proportionate to the size of the plant and the size of the pot, are different things from potting loosely. In all flowering plants the compost should be placed tight round the roots.

We commend these matters more especially to amateur and window-gardeners, with some of whom we find we have got into a scrape—rather a pleasant one, however, as we think we can see the way of getting out of it. We are reminded—"You have several times spoken of the impropriety of sowing and planting when the ground was wet, why, then, so anxious to plant after the last rain?" Again: "We have pretty well analysed and stored-up all your directions and principles about watering in-doors and out of doors, but we can hardly explain them in unison with a practice we noticed—one of your assistants syringing flower-beds in the afternoon of a hot sunny day." Well, in the first place, we have, for reasons often given, declined even digging ground when it is very wet. We would for similar reasons decline planting in ground very wet, because it is almost impossible to leave the ground behind you in a nice healthy open condition. But the rain made our ground in a nice pliable condition instead of dust-dry. It has never yet been soaked, but it had as much moisture as would render planting easy, and yet not supersede the necessity of watering each plant set out. There was, therefore, no likelihood of pothering the ground, otherwise there would have been no planting. But as it was, the water required for watering was reduced to a minimum, as the surrounding ground was not in a dry heated state to absorb it immoderately. In unison with the rule, water sufficiently when wanted, and wait until your services are again required, the word "sufficiently" should in the case of fresh-turned-out plants be understood to mean not deluging, but giving merely as much as is necessary, for much moisture will cool the ground at once, and cool it more by an increase of evaporation; so that a little water and often will often be better than a great deluging. Again, though the roots are moist they will not grow and absorb moisture at once; and in a hot sun the leaves will suffer from an excess of evaporation over absorption, and though, perhaps, shading would be a good remedy, we found the next best to be dewing the foliage gently from an engine, by which means a few potfuls of water will go over a large piece, and the vapour that rises from the heated soil is also very grateful to such fresh-turned-out plants.—R. F.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

MANURING A VINE-BORDER (G. Morris).—Manure as soon after the fruit is cut as you like. If you did it now and used much water, most likely the Grapes would crack.

MONOCOTYLEDON ENSEIFERUM CULTURE (W. X.).—From 55° to 60° will be a temperature quite high enough for the plants, with an increase during the day. Plenty of air will insure sturdy growth. Let them alone; if fresh-potted they will thrive in 60° until rooting freely.

VINES IN POTS (Z. C.).—Mr. Elphinstone published a little pamphlet on their culture, but it is out of print. There is a good essay by Mr. Appleby on the subject in No. 17 of this Journal, which you can have free by post if you remit four postage stamps.

GRAPE COLOURING (J. Price).—You must continue damping the floor, but omit the syringing. Give abundance of air, for depth of colour much depends upon that.

SEEDLING STRAWBERRY (B. W. Knight).—The fruit sent is very juicy and of excellent flavour; but we can give no further opinion on the merits, so much depends upon whether it is really a new variety, its habit, prolificacy, &c., all which can only be determined by a careful examination of a growing plant.

INSECTS (A Subscriber).—We found no caterpillar in your communication. The spots on the leaves seem to have been produced by a vegetable mould, and not by the action of an insect. Kollar's treatise on insects injurious to fruit trees, was translated by Miss Loudon, and will suit your purpose.—J. O. W.

RETAINING OLD MELONS OR PLANTING FRESH (W. W.).—Each is best under the different circumstances. If the plants have not borne heavily, and the vines are fresh, good second or third crops may be obtained from the same plants; but if, for securing fine flavour, the soil and the atmosphere have been kept rather dry, the plants are apt to suffer a little in consequence, and in that case, replanting with fresh strong plants is the best plan. It also gives an opportunity for cleaning the place, and at least resurfacing the beds. The plants must be pretty good to do well after the middle of July, as late autumn Melons are generally of little use if September and October happen to be dull and wet.

THRIPS AND RED SPIDER ON MELONS (W. D.).—The atmosphere of your pit has been kept too dry. Smoke two nights in succession with shag tobacco; syringe lightly the following morning; shade from bright sun, and keep the air of the pit moist. The foliage must be dry before smoking. This will destroy thrips; but no amount of tobacco smoke will destroy the eggs; therefore, whenever thrips appear smoke again, and continue to do so until the pest is thoroughly exterminated. Choose a fine day to deal with the red spider. Dissolve as much gum arabic as will lie on a penny in a pint of rain water, and when that is done mix half a pound of sulphur with it, forming the whole into a paste-like substance, which is put into three gallons of rain water heated to 120°. Have the hot-water pipes heated to 160° by 4 p.m., then shut up the pit, and syringe the Melons with the sulphur solution, wetting every particle of the infested leaves and stems, and all the available evaporating-surface—as walls, &c. Syringe the hot-water pipes with the same mixture until the pit is full of steam. Gradually lower the temperature of the heating-surface; keep the pit close and shaded from bright sun for a few days, when the Melons will be clear of red spider, and no fear being entertained of its return (for the sulphur left on the walls, &c., will act as a preventive), treat them in the usual way. This will not only kill red spider, but the moisture by which it is accompanied will materially aid in exterminating thrips.

SULPHUR-DREDGER (Orchidophilus).—We have used it for some years, and can confidently recommend it. You can have Indexes of nearly all the early Volumes of THE COTTAGE GARDENER.

YOUNG VINES NOT FLOURISHING (An Amateur, Nantwich).—We have nothing to add to our recommendation last week. The Vines are weakly, and this probably arises from their being planted too deep.

DESTROYING GOOSEBERRY CATERPILLARS (Mrs. F. S. A.).—We believe the most effectual mode is to have the caterpillars picked off by hand. One or two women will clear a large plantation in a day. A comprehensive mode of destroying these pests is to dust the leaves thoroughly with fresh white hellebore powder. Cover the surface of the soil 2 inches deep with spent tanner's bark, removing it in the autumn and burning it. This will prevent the occurrence of caterpillars next year.

FORMAN'S CREW APPLE (A Subscriber).—We have made every search for the origin of the name "Crew," but have failed. Can any of our correspondents inform us?

SEEDLING CALCEOLARIA (H. Major).—Very fine as to size—1½-inch across—and good as to colour and marking.

NAMES OF PLANTS (A Lady Subscriber).—Nos. 1 and 2, forms of *Selaginella Martensii*; 3, *S. Galeottii*; 4, *S. cnsia*. (*R. W. B.*)—*Escallonia grandiflora*, a hardy shrub. (*Homo*).—1, *Lastrea Filix-mas*; 2, *Blechnum boreale*; 3, *Lastrea dilatata*; 4, *Scopolendrium vulgare*; 5, *Athyrium Filix-femina*. (*D. C. D.*)—1, *Eunymis europæus*; 2, *Philadelphus coronarius*; 3, *Staphylea pinnata*; 4, *Lychnis diurna*. (*P. S.*)—1, *Chenopodium Bonus-Hemiscus*; 2, *Veronica serpyllifolia*; 3, *Hieracium pilosella*; 5, *Rumex*, too young to determine—looks like *sanguineus*. (*A Subscriber, E.*)—*Echynanthus ramosissimus*. (*B. E.*)—1, *Corydalis lutea*; 2, *Gomphocarpus fruticosus*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY SHOWS.

JUNE 27th to 30th. SHEFFIELD. Sec., Mr. H. Warhurst, Cremorne Gardens, Sheffield.

JULY 2nd. PRESCOT. Sec., Mr. James Beesley.

JULY 20th to 24th. WORCESTERSHIRE. Sec., Mr. J. Holland, Chesnut Walk, Worcester. Entries close June 20th.

AUGUST 29th. HALIFAX AND CALDER VALE. Sec., Mr. W. Irvine, Halifax.

SEPTEMBER 2nd. COTTINGHAM. Sec., Mr. J. Britain.

JAPANESE FOWLS.

HAVE any efforts been made for the importation of the new breeds of fowls seen in Japan by Mr. Fortune?

At Nagasaki, he says, "I observed some striking and beautiful kinds of fowls. These were rather above the ordinary size, but were remarkable for their fine plumage. The tail-feathers were long and gracefully curved, and fine silky ones hung down on each side of the hinder part of the back. Bantams were also plentiful, and bold independent-looking little fellows they were."

At Yokuhama Mr. Fortune again remarks, "The different varieties of fowls struck me more than anything else. The kind which I had seen at Nagasaki was here also, and, in addition, a pure white bird with a fine long arched tail, and long silky

feathers hanging down from each side of the back. This is a very beautiful bird, and well worth being introduced into Europe, if it is not already here."

[Since the above was extracted, we see the following notice in the Report of the Acclimatisation Society:—"A pair of Japanese fowls presented by A. D. Bartlett, Esq., and now under the care of Mr. Bush, have passed the winter in his aviary, and are now laying. Their eggs are of a deeper colour and rounder than those of the Cochins-China fowls." These may represent one of the varieties seen by Mr. Fortune. We wish the Report had included a description of the fowls.]

THE THORNE EXHIBITION OF POULTRY.

IN accordance with the practice for many years past, this excellent Show of poultry was held in the grounds opposite the Hall of Makin Durham, Esq., giving the whole affair a most rural and picturesque appearance. To the kindness of the worthy proprietor in permitting these annual exhibitions to be thus held the Society are deeply indebted, the Exhibition causing an influx of strangers into Thorne that few parties from mere hearsay could credit, and proving itself quite an annual *réunion*, anxiously looked forward to for many weeks previously. The present year's Show far surpassed those hitherto held in the number of entries, whilst even a cursory glance at the printed catalogue proves that nearly all of our most reputed poultry amateurs competed. The grounds enjoy the advantages of timber of many years' growth, whilst the constant fitting to and fro of the rooks overhead gave a novelty rarely to be met with at such exhibitions. The day was luckily favourable, the fair visitants were mostly decked in their gayest holiday gear, every one seemed determined to enjoy themselves, and, consequently, the whole scene was one of unalloyed pleasure and satisfaction.

The pens (considerably above three hundred), were very nicely arranged in single line beneath the shade of the trees, which added materially to the comfort of both the poultry and the Pigeons. The Rabbits, however, seemed quite to enjoy the solar rays, and we will dismiss this latter branch of the Show by simply stating most of the specimens were very good. Considerable attention was drawn also to a temporary grotto-like erection, composed of a full complement of gypsum for rockery, ornamented with a variety of growing ferns, flowers, &c., the whole surmounted by a large preserved white sea bear, the oddity of the affair being greatly increased by the fact of the aforesaid gentleman wearing for this occasion a very thick great coat of moss, covering all else save his head, feet, and neck. Under the great summer heat that prevailed, had animation existed no doubt poor Bruin would have felt as desirous of throwing off every extra garment as did most of his visitors. Mr. Cason's and Mr. Burr's grottos were at once pleasing and interesting bye-plays to the general scene, the one with the addition of suitable canvass, representing a highland glen, the other an eastern drawing-room. Under so varied an attraction, heightened by the almost incessant performances of the Thorne Brass Subscription Band, it will be no matter of surprise to hear that the money taken at the doors showed a very gratifying advance on the amount derivable on previous occasions.

Another great cause of the success of the Thorne Society arises, without doubt, from its happy possession of one of the most obliging and business-like Hon. Secretaries imaginable. Courteous alike to all, yet keeping the success of the proceedings under constant attention, Mr. Richardson well merits the good opinions entertained of him by his colleagues, and affords a good example to not a few of our poultry secretaries that might be followed with the like welcome results, if applied to their particular societies.

At this particular season we naturally expect to find poultry fast approaching moulting time, and on no variety of fowls does want of condition tell with greater force than on *Spanish*. This class was, nevertheless, a good one; but it appeared in not a few instances a pity to place really well-bred birds before the public in so sad trim as that we now refer to. A powerful objection to thus exhibiting them is simply this, that while each pen-feather contains blood, it offers, under close confinement, the greatest of all possible inducements to fowls of any breed to become absolute cannibals—so much so that oftentimes, unsatisfied with the immature feather alone, they proceed to eating away piecemeal the living flesh of their companions. We draw par-

ticular attention to this fact, as this morbid desire if once contracted, is one of the most difficult of any of the evil practices of exhibition poultry to eradicate; and it is a propensity that any little injury by which blood is drawn at once brings into action, if the unfortunate sufferer is unhappily placed in a position where escape is unavailable.

In *Cochins*, Buffs were first, and Partridge-coloured second, both colours being well shown. Although only two pens of *Game* (Whites or Piles) were placed, they were very creditable ones. It was in the Black-breasted Game fowls and other Reds that competition reached its highest point. Here Messrs. Adams, Boyes, Brierley, Fletcher, Helliwell, Julian, and several other noted Game-breeders tried their hardest for the mastery. As must be the event where such a rivalry existed, the heaviest in competition prevailed, and the result proved how equally the honours became distributed. Mr. Fletcher gained the silver cup for single Game cocks with a truly magnificent "stag" Black-breasted Red, and it was the universal opinion that it will be long before we shall look upon his like again. For the Silver Game cup, for a pen of three, Mr. Adams and Mr. Julian, both exhibitors from Beverley, were evidently a long time in close balance, the Judge (who officiated openly) evidently scrutinising each pen again and again as though almost hopelessly striving to find a fault with either. After the most rigid inspection, a faulty eye in one of Mr. Julian's hens gave Mr. Adams the superiority. The silver cup for *Game Bantams*, on the contrary, was a mere "walk over" to the noted pen of Mr. H. D. Bayley.

The *Red Caps* shown were remarkably good, and in the class for Any variety of chickens a pen of Black Red Game and another of White Dorking chickens were so equally perfect that the Judge "admitted it an injustice to either pen to obtain a second position." This anomaly will occasionally occur where many breeds compete in the same class.

A class for *Single Cocks* of any breed brought into competition a great variety, a Grey Dorking being first, a Golden Poland the winner of the second prize. In this class no less than seven excellent Game cocks were shown; but as a class for single Game cocks existed, it is scarcely just this variety should be admitted into a competition where a position is already afforded them in one particularly devoted to Game cocks only.

The *Aylesbury Ducks* were worthy of mention, Mrs. Seamons holding her customary place in the prize list. The *Geese* and *Turkeys* were also good.

In the *Pigeons*, almost every class was well filled, but no new variety presented itself. The Show closed the same evening, and every bird was forwarded to its owner without misadventure of any kind.

SPANISH.—First, H. Beldon, Bradford. Second, J. Dixon, Bradford. Highly Commended, F. Siddall, Halifax; J. Brown, Sheffield.

COCHIN-CHINA.—First, Messrs. H. & G. Newton, Garforth, Leeds. Second, R. White, Broomhall Park, Sheffield. Commended, Messrs. H. & G. Newton.

DORKING.—First, R. M. Stark, Hull. Second, J. Sledmore, Epworth. Highly Commended, E. Jefferson, Epworth; Hon. T. C. H. Hawke. Womersley. Commended, Master L. Fosbrooke, Hatfield; Hon. T. C. H. Hawke, Womersley.

GAME (White and Piles).—First, H. Adams, Beverley. Second, T. Walker, Doncaster.

GAME (Black-breasted and other Reds).—First, H. Adams, Beverley. Second, H. M. Julian, Beverley. Highly Commended, Messrs. Sale & Bentley, Crowle; G. Helliwell, Walkley; C. W. Brierley, Rochdale.

GAME (Duckwings and other Greys and Blues).—First, C. W. Brierley, Rochdale. Second, G. Helliwell, Walkley. Commended, H. Adams, Beverley.

GAME (Any breed).—Silver Cup, H. Adams, Beverley. Highly Commended, G. Helliwell, Walkley; H. Adams; H. M. Julian, Beverley. Commended, H. Beldon, Bradford; J. Fletcher, Stoneclough, Manchester.

SINGLE GAME COCK (Any breed).—Silver Cup, J. Fletcher, Stoneclough, Manchester. Highly Commended, W. Boyes, Beverley; H. M. Julian, Beverley; G. Helliwell, Walkley; G. Valentine, Habiasthorpe. Commended, H. Crossley, Broomfield, Halifax; H. Beldon, Bradford; G. Marshall, Barmbro'; H. Adams, Beverley; C. W. Brierley, Rochdale.

POLANDS (Any variety).—First and Second, J. Dixon, Bradford. Commended, H. Beldon, Bradford.

HAMBURG (Silver-spangled).—First, H. Beldon, Bradford. Second, J. B. Hepworth, Bearswood Green. Commended, J. Dixon, Bradford.

HAMBURG (Golden-spangled).—First, C. W. Brierley, Rochdale. Second, J. Dixon, Bradford. Highly Commended, H. Beldon, Bradford. Commended, Messrs. Burch & Bolter, Sheffield.

HAMBURG (Silver-pencilled).—First, H. Beldon, Bradford. Second, J. Dixon, Bradford. Highly Commended, J. Harrop, Walkley.

HAMBURG (Golden-pencilled).—First, C. W. Brierley, Rochdale. Second, S. Smith, Northowram, Halifax. Highly Commended, H. Beldon, Bradford.

ANY FARMYARD CROSS.—First, Messrs. Burch & Boulter, Sheffield.

Second, H. Beldon, Bradford. Commended, J. Calvert, Thorne; Messrs. H. & G. Newton, Garforth; T. Downing, Thorne.

GAME BANTAMS (Any breed).—Silver Cup, T. H. D. Bailey, Ickwell House, Biggleswade. Highly Commended, C. W. Brierley, Rochdale. Commended, J. Crossland, Wakefield; W. Silvester, Market Hall, Sheffield; E. Yearley, Wisewood, Sheffield.

BANTAMS (Silver or Golden-laced).—First, H. Beldon, Bradford. Second, E. Yearley, Wisewood, Sheffield. Commended, R. M. Stark, Hull; J. Staley, North Collingham, Newark.

BANTAMS (Black, White, or any colour).—First, J. Dixon, Bradford. Second, R. M. Stark, Hull.

ANY BREED OR CROSS.—First, R. M. Stark, Hull (Grey Dorking). Second, J. Dixon, Bradford (Golden Poland). Highly Commended, Hon. T. C. H. Hawke, Womersley (Brahma); R. White, Sheffield (Cochin). *Hens*.—First, H. Beldon, Bradford (Spanish). Second, J. J. Cranidge, Crowle (Red Caps). Highly Commended, W. Boyes, Beverley (Brown Red); E. Brown, Sheffield (Spanish); C. W. Brierley, Rochdale (Black Red Game); R. Williamson, Wheatley (Spanish); Commended, Hon. T. C. H. Hawke, Womersley (Cochin); J. Gibson, Hatfield (Golden-spangled Hamburg).

CHICKENS (Any pure breed).—First, A. Bell, Burnley (Black Red Game). Second, M. Durham, Thorne (White Dorking). Highly Commended, J. Dixon, Bradford (Silver-spangled Hamburgs); T. Pidd, Crowle (Brown Red Game).

GUINEA FOWLS.—First, J. Dixon, Bradford. Second, H. Merkin, Driffield.

TURKEYS.—First, Miss Blacker, Mooredens. Second and Commended, J. Dixon, Bradford.

GEES.—First, J. Dixon, Bradford. Second, Hon. F. C. H. Hawke, Womersley. *Gibbs*.—First, G. Outwin, Hatfield Park. Second, J. Lee, Sykehouse. Highly Commended, R. Longhorn, Armpyn. Commended, Miss Aldam, Holmes, Epworth.

DUCKS (Any breed).—First, J. Dixon, Bradford. Second, H. Beldon, Bradford.

DUCKS (Aylesbury).—First and Second, Mrs. M. Seamons, Aylesbury.

RABBITS.—*Buck and Doe*.—First, G. Woodley, Thorne. Second, I. T. Spencer, Doncaster. Highly Commended, G. White, Thorne; J. Holmes, Hatfield. *Buck*.—First, W. Trimmingham, Thorne. Second, J. Sunderland, Halifax. *Doe*.—First, J. Greaser, Thorne. Second, J. Sunderland, jun. Highly Commended, R. Gravit, Thorne. *For weight*.—First, G. Woodley, Second, J. Gregory, Hatfield.

PIGEONS.

CARRIERS.—First, W. Carlton, Howden. Second, J. B. Hepworth, Beerswood Green. Highly Commended, S. Robson, Brotherton. Commended, H. Beldon, Bradford; H. Yearley, Birmingham.

CROPPERS.—First, H. Beldon, Bradford. Second, S. Robson, Brotherton. Highly Commended, H. Yearley, Birmingham; E. Brown, Sheffield; C. W. Brierley, Rochdale.

TUMBLERS.—First, H. Beldon, Bradford. Second, J. Mann, Pigburn. Highly Commended, R. Gravit, Thorne.

JACOBS.—First, C. H. Brierley, Rochdale. Second, W. Riley, Belton. Highly Commended, T. M. Stoker, Darrington; H. Yearley, Birmingham.

NUNS.—First, F. Key, Beverley. Second, H. Beldon, Bradford. Commended, H. Yearley, Birmingham.

TRUMPETERS.—First, S. Robson, Brotherton. Second, W. Carlton, Howden. Highly Commended, A. Beldon, Bradford; — Yearley, Birmingham; F. Key, Beverley.

TURBITS.—First, H. Beldon, Bradford. Second, Messrs. Holding & Robinson, Beverley. Commended, E. Jobling, Newcastle.

FANTAILS.—First, F. Key, Beverley. Second, E. Brown, Sheffield. Highly Commended, E. Jobling, Newcastle.

OWLS.—First, H. Beldon, Bradford. Second, E. Jobling, Newcastle. Highly Commended, H. Ravenhill, Doncaster; W. Hattersley, Sheffield. Commended, H. Yearley, Birmingham.

EXTRA STOCK.—Commended, J. Greaser, Thorne.

Mr. Edward Hewitt, of Eden Cottage, Sparkbrook, near Birmingham, awarded the prizes to poultry, Rabbits, and Pigeons.

THE BRADFORD SILVER CUP BLACK BANTAMS.

IN your remarks last week relative to Bantams at the Bath and West of England Poultry Exhibition you say, "Black ones secured the silver cup for the best pen of any breed of Bantams shown. They were excellent; but it was rumoured among amateurs the address of the owner was assumed—a report scarcely credible, so long as even the number of the house is added to the general address in the printed catalogue."

Having given currency to an impression, which, taken in conjunction with the late remarkable Black Bantam controversy, is calculated to throw suspicion on either the exhibitor or the birds, allow me to say the Bantams belong to my daughter, and have been exhibited thrice, each time successfully. In addition to your own report, a contemporary having characterised the pen as "perfect Blacks," it is, perhaps, unnecessary to say more than to inform certain "amateurs," that the name Kate Charlton is very little indeed of a myth, and that the address in the catalogue is the residence of—T. J. CHARLTON, Bradford.

DISTINCT VARIETIES OF DORKINGS.

It appears to me that the different breeds of Coloured Dorkings are very imperfectly classified. Although I do not pretend to know all the varieties, yet I know that besides Silver-Greys there is a variety in which the hens are of a light grey colour with a light hackle, and another of a dark grey colour with a dark hackle, and it is to these two varieties that I allude.

I think that it would be an improvement if each of these varieties had distinguishing names of their own. For instance: Parties advertising their stock for sale in THE JOURNAL OF HORTICULTURE should state which of these varieties it is they offer, so that those wishing to improve their breed by a change would have an opportunity of knowing from whom to purchase stock of the same colour as their own.—A NORTH BRITON.

[The two birds you mention are not sufficiently distinct to render necessary a separate classification of them; as very often the darker birds get much lighter after the first moult, and it often happens that the two colours, as described by you, are seen in the same brood, the produce of the same parents.]

BEE SEASON IN EAST LOTHIAN.

IN complying with the request of "A. W.," page 446 of THE JOURNAL OF HORTICULTURE, on the bee season, and "our success and failure" here, East Lothian, I have to state that this season, though warmer than last, has been no better for the bees obtaining food, owing to the frequent showers and dull days. I had my first swarm on the 11th, the same day I had one in 1862, one on the 14th, and one on the 17th from the artificial Ligurian hive which I made last year, July 26th. I expect other four as soon as the weather will allow them to come, and these I intend to make artificial Ligurian hives, by taking a bar-frame from my old Ligurian, depriving them of their own queen. The first swarm I put into a Stewarton-hive, being anxious to try that kind, believing it to be good for making honey.

On the 12th I took out two bars, one full of young brood in all stages, the other containing a good number of drones in all stages likewise, and put them into an empty box along with two empty combs, being determined to use every means to keep the Ligurians pure. In giving the queen the black bees of the hive I took the day previous, I did not want her to get any black drones, and I thought we had fallen on a simple method of doing this, as well as a secure one. I had the perforated zinc which some of your correspondents use for keeping out the drones from the supers. With it I covered the box containing the young brood, and by turning up the one containing the bees, placing the other on the top, I expected a good many bees would go into the upper one through the perforated zinc. Being aware, however, that all would not leave the queen, it would still make it easier to keep back the drones and queen. Notwithstanding a considerable amount of beating on the under hive containing the bees and queen, we could only induce a few to go through the zinc. We then had to resort to the old method of shaking them out on a sheet, a few at a time, and making them run into the hive, which they did at once, one keeping a piece of the perforated zinc ready at the mouth of the hive to prevent any drones entering. This was not much required, as there were only thirteen drones, which were easily secured before entering, and the queen also. They were all into the hive and on the stance in a quarter of an hour. I gave her a good feed at once, and in the afternoon they had begun carrying bee-bread, and although giving unmistakable symptoms of being in want of a queen till the following day, they are now working as well as any.

I intend to do other five or six in the same manner, and then send the whole of the Ligurians, old and young, away to a neighbour's garden, who has only two hives, which I will bring here. They will then be two miles from the nearest black bees, and where it is a considerable deal colder, being much higher and at the foot of the hills. The Ligurian drones in their hymeneal excursions may come this way, but I do not anticipate that the black ones will go into such a cold place. At all events, it is the only chance I have of keeping them pure, and had it not been that so many around here had lost all their stocks, I could not have managed it.

Some wishing to purchase from me the pure stock I have been at this trouble, otherwise I am disposed to think that a mixed breed or hybrid would be an improvement. I have obtained

three of Woodbury's straw bar-frame hives from Neighbour and Sons, and I consider them a great improvement on the wood ones. I will never allow my bees to be all the winter in these again. They may be used in the summer, when there is no moisture to condense in the inside of the hive, or where the movement of the bees prevents it; but in winter they are always wet to a certain extent; but I intend to put straw tops on the wood, which will help them a little.—ALEX. SHEARER, *Yester*.

AGE OF QUEENS—DISTANCE BEES FLY.

THE age of queens is sometimes difficult to ascertain when bees are left entirely to themselves; they being able to replace the mother of the hive with a young one at the proper season if any accident happen to her. But in the case replied to at page 335 there is no foundation for doubt, and it served for an experiment to prove that the impregnation of the queen lasts her lifetime.

In 1848 I put two swarms together, leaving to themselves to decide which queen should be the ruling sovereign. The surviving queen appeared to be a little wounded in the conflict, both her wings being peculiarly cut, and this prevented her from flying. She had always to be watched at swarming time, and she led off swarms for seven successive years. She was of an unmistakeable appearance; for besides her injured wings she was very little larger than a worker, which rendered all my attention necessary to detect her.

It is the custom here for people to remove their hives at different seasons of the year. When they remove them in spring, a mile or a mile and a half suffices to prevent their coming back to the place they were removed from, and in summer two miles will suffice; but in the month of August, when taken to the heather, it is a regular thing for them to come back in great numbers the distance of three miles and a half. They are not so apt to come back in the height of the working season as when it is past and when necessity calls them to a distance.

The nature of the case described at page 336 was of twelve hives, which stood at Nempfar in the parish of Lanark. They were removed at three different times, four at a time, on a hand-barrow every other night to the parish of Carmichael fully six miles, and a pretty straight road—almost a direct line. There was a patch of heather about midway between these two places, which was a little earlier in bloom than the heather was at their new stand. This would entice them back to their old working-place. Part of the bees from every hive came back to their old stand and clustered till the following day, and then departed, probably in search of their hives. The people in Arran say that it is common to see bees on the Holy Island at Lamlash Bay, which is allowed to be a distance of three nautical miles from shore to shore, and no bees were kept on that island at that time. I have seen bees at least two miles from the shore between Arran and the Cumbræes alighting on the steamboats, which will show how far a bee will fly without alighting.—A LANARKSHIRE BEE-KEEPER, *Blantyre*.

DEATH OF QUEENS—BEE-KEEPING IN STAFFORDSHIRE.

I ENCLOSE two Ligurian queens, and shall be glad of an opinion upon them. One is a supernumerary that came off with a swarm, and is a fine insect and fairly coloured. The second is a very fine, well-coloured queen, and is, I fear, the old queen—i.e., one reared last year, from a storified-hive. The hive is densely peopled, but the bees have not yet taken to the super. If my opinion is correct, I much regret her loss, as she bred finer-coloured workers than any of my other queens—I think fully equal to my original one received from "A DEVONSHIRE BEE-KEEPER."

My four stocks all passed safely through the winter, and were strong and forward in the spring, and during the blossoming of the damson trees increased in weight. Since that time the weather has been most unpropitious, and still continues so. My experiments have, however, been much more successful than those made last year. I made my first swarm on the 9th, by taking four frames with brood and bees out of the swarm of June 4th, 1862 (as I believed that hive to contain the old queen), and placing them in a four-frame hive. I then put this and the parent hive side by side, when it was soon evident

that the queen was in the small hive, as there was great agitation in the old one. I placed the swarm on the stand of another stock, and in a day or two shifted them into a ten-frame hive, supplying them with four new frames of empty comb, and at the same time giving the old stock two frames of empty comb to discourage the building of drone-combs. Had the queen not been in the nucleus-box, I should have kept the bees in that hive until the young queens made their appearance, and then have shifted them into a larger hive.

On the 20th I made a second swarm, by abstracting a single comb with a sealed royal cell into a nucleus-box, and placing it on the stand of another stock. On the 23rd a swarm came out of the old hive, and another will, if the weather permit, come off soon, as they have been piping strenuously.

I am feeding the swarms liberally, as there is no honey to be had, and a poor prospect for the future, as the land is sadly burned up for want of rain. My hives were fully ventilated until the 8th of February, and the boxes consequently were perfectly dry, without the slightest condensation on the windows. In March, the condensation was considerable, but did not produce any evil consequences. Owing to the mildness of the season, the loss of weight in my hives was very considerable, about 10, 9, 8, and 7 lbs. in the four stocks respectively, from the 1st of November to the 1st of February. Where would they have been if they had only weighed 10 lbs. nett in September, as recommended by "G. F. B.?"

The advantages of the new arrangement in bars, and having a space between the bars and crown-board are very great, and most materially contribute to the well-being of the bees. The ventilation is rendered complete and perfect, as the current passes through between all the combs, and out at the central hole in the crown-board. Formerly I used to find a great deal of damp at the sides of the hives away from the centre. At the same time the approximation of the combs seems to greatly favour the breeding of the queen in the spring, as a much smaller number of bees covers a greater surface of combs than when the bars were placed at a greater distance from each other. I also find the indiarubber gloves invaluable.—J. E. B.

[The smaller of the two queens was a virgin, and was, doubtless, a supernumerary one that accompanied the swarm. The larger we ascertained to have been unquestionably impregnated, and regret, therefore, to confirm your fears as to her being the old queen. This is not the first instance in which we have found valuable queens fall victims to the rivalry of their daughters, either immediately before or just after the issue of a swarm, and we are inclined to believe that it is more common than is generally supposed.]

OUR LETTER BOX.

DUCKS AT BATH AND WEST OF ENGLAND SHOW.—The Cup for the best pen of Ducks was awarded to Mr. Rodbard's Rouens, and not to Mr. Fowler's Aylesburys.

ROUEN AND EAST INDIAN DUCKS (*W. W.*).—The Rouen is much the larger bird. The East Indian when pure bred is a small compact Duck. Both breeds are prolific, and the early laying is much regulated by the age and condition of the birds themselves. This season the Rouen Ducks generally have laid better than the East Indian.

PROFITABLE BREEDS OF FOWLS (*S. T.*).—In the neighbourhood of large towns, where new-laid eggs are in demand, either Cochins, Brahmas, or Spanish would be good birds for you, as they require but little range. If you have a large space for them, then any breed will thrive with you. Young healthy birds should be selected, as they lay earlier than older ones; and pullets for early laying should be introduced annually, and the older hens got rid of.

COLOUR OF GREY DORRING CHICKENS (*E. A. C.*).—Grey Dorking chickens vary very much in colour when first hatched, many appearing almost white and others as nearly black. The first feathers are often speckled with white, which disappears as the birds get older, and others seem to be as nearly black and then alter.

CROSS BETWEEN CANARY AND YELLOWHAMMER (*Wooton*).—We are not aware of any instance of the Canary and Yellowhammer having been cross-bred, but we see no reason why they should not breed together. The most probable British bird that the Yellowhammer would pair with would be a hen Greenfinch.

REARING YOUNG NIGHTINGALES (*An Old Subscriber*).—To rear young Nightingales feed them on fresh beef, scraped fine, and hard-boiled eggs, also chopped fine, with a little scalded bread; and when they are fledged, leave off the bread and give them occasionally a few mealworms. Keep them in a quiet place and shaded from the sun.

LIGURIAN BEES (*W. W.*).—If you write to T. Woodbury, Esq., Mount Radford, Exeter, he will give you all the information you need.

TAKING HONEY (*S. B.*).—Honey should be taken in the autumn, as soon as gathering is over and breeding either diminishes or ceases entirely. The mode of uniting bees by driving is fully described in pages 45 and 46 of "Bee-keeping for the Many."

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 74.6° and 51.0° respectively. The greatest heat, 97°, occurred on the 5th, in 1852; and the lowest cold, 35°, on the 30th, in 1849. During the period 152 days were fine, and on 100 rain fell.

PEAS, AND HOW TO GROW THEM.

serve the table no vegetable contributes more than the Pea—the Potato always excepted. It does moderately well on all soils, and in all parts of our climate, high elevations excepted. Peas, however, do best on lightish loams, and indifferently on a clay formation. For a very early crop the soil can hardly be too light, for it is not quality nor quantity that is aimed at, but extreme earliness. A somewhat stronger soil is best to afford a succession of early Peas, and a deep, loamy soil is what suits main crops. Heavy soils with a good deal of marl in them afford excellent Peas late in the season, and in dry summers heavy soil is better than light. Taken

in a general way, Peas delight in deep, rich, and friable loamy soil, and by well exposing heavy soil to the influence of the weather, and forking it over on dry, frosty mornings, the most tenacious soil may be brought into a condition to suit this crop. Trenching is almost necessary to secure good Peas; and an open site, but sheltered from strong gales, is essential. A liberal dressing of manure is necessary, and should be well mixed with the soil, for when the roots are very highly fed the Peas run too much to haulm, become gross instead of sturdy, and never produce so abundantly as those on moderately rich soils.

Peas may be divided into numerous sections, but I shall be content to deal with them in three ways. First, in small gardens; Secondly, in moderate-sized gardens; and Thirdly, in large gardens. I will provide for a succession of this prime esculent in all three cases, and give the earliest period they have come into bearing with me and my neighbours, and the latest period at which they may be expected.

The earliest period we have heard of Peas being gathered in this county (Yorkshire), was the Early May, on the 29th of that month, and I have gathered Peas myself on the 17th of December, and have heard of their being gathered on the 25th of that month. These, however, are extreme cases, and are no criterion to work by. In well-sheltered, sunny localities, and on light soils, the 7th of June is a very fair time to gather early Peas, and between that date and the 15th Peas may be expected in quantity. On heavy soils they will be a fortnight later, and in high, bleak, and cold soils, a fortnight later still. From that time Peas can be had until the frost cuts them off.

Very much depends on the weather, and the condition of the Peas, to determine the amount of frost that will destroy them. If the weather has been hot or dry some time before the frost occurs, 6° of frost will not harm them, and in one case I knew them stand 10° of frost

without sustaining any great injury; but if the weather has been warm and moist prior to a frost, very few degrees below freezing will destroy them.

1ST. PEAS IN SMALL GARDENS.—Large or tall growers are not adapted to limited areas. They take up too much room, and overshadow everything else. But, "I like Marrowfats," I hear some one say. Well, and you shall have them. Dig or trench the Pea-ground as early as possible in the autumn, giving a good dressing of manure, and if the soil be heavy or tenacious throw it into ridges as roughly as possible, throw it back early in February, choosing a dry frosty morning for the operation, breaking and pulverising with a fork (spades are puddle-makers on heavy soils), all the hard lumps not frozen, and leave the whole as level as possible. Any time after the 15th of February sow, when the weather permits, a gill of Dillistone's Early Prolific, and the same quantity of Sangster's No. 1, or its synonyme Daniel O'Rourke, choosing the warmest corner and most sunny part of the land set apart for Peas. Allow 3 feet between the rows; and if you like Spinach, and have the ends of the Pea-rows pointing north and south, sow a row between the Peas, and a few Radishes may be sown between also. The drills should not be deeper than an inch, and if the Peas be covered that depth it is enough. If sown much deeper the seed will rot, if the season be cold and wet, and what we very often blame the seedsman for too often is our own fault. Should any fear of mice being troublesome be apprehended, rub the moistened Peas in red lead before sowing, and set a brick-trap or two to prevent their nibbling the points of the shoots off when they appear, and if slugs are troublesome sprinkle soot over and around the Peas. There is another enemy, and that is my friend the sparrow. Black thread strung about 6 inches above the Peas hung with bits of glass, will keep him at bay; but pray do not kill him with poisoned wheat, he will make amends for his thieving propensities by eating thousands of caterpillars.

Early in March sow a row, a gill or a pint, according to the quantity of ground, of Sangster's No. 1, and the same of Bishop's Longpodded. Sow a little Spinach and a few Radishes, or a bit of Lettuce seed between the rows to gather or cut early. Never mind what this body or t'other body says about their spoiling Peas, for I follow this plan myself, and get a few nice dishes of Spinach for my master's table, some nice Radishes to eat with cheese, and a few Lettuce plants to transplant, and these are off before the Peas attain any great height, so that there is no fear of their being smothered.

Prepare some Larch or Spruce branches, for those make the best pea-sticks, Beech and Hornbeam are the next best, and Hazels will do well. Point those neatly, and set them in a corner to be ready against the time when the Peas are 3 inches high, when draw some earth to the Peas and put in the sticks on both sides of the row, keeping them as wide at top as at bottom, and not letting them meet at top, as if Peas were grown to be huddled and smothered. The sticks are best when a little longer than the specified height of the various kinds,

for a wet season induces them to grow taller, and a dry season dwarfer. But the main point of all in sticking Peas is to place them firmly in the soil. If placed so that they move to and fro in a gale, well-filled pods need not be looked for. The pea-haulm is so brittle and so liable to be broken, that good twiggy sticks, and firm set, is a main point in Pea-growing. Sticks for sorts growing 3 feet high should be 4 feet long, and all 1 foot longer than their height, so as to allow for the part thrust into the soil, and a little above, to meet the exigencies of the season.

Sow another crop on the 15th of March, employing Scimitar and Perfection (Veitch), allowing 4 feet between the rows. On 1st of April sow Perfection and Flack's Imperial Victory; again on the 15th sow Alliance, and on the 1st of May, and 15th of same, a sowing of Perfection to be made. June 1st, sow Hairs' Dwarf Mammoth, and on the 15th, the Prizetaker, synonyme Bellamy's Improved Early Green Marrow. Finally, sow Bishop's Dwarf, and Burbridge's Eclipse on the 1st of July. The following table will show at a glance, the beginning, half-way distance, and the end:—

Time of Sowing.	Sort.	Weeks Required to Mature from sowing in Average Seasons.	Height in Feet.
Feb. 15.	{Early Prolific	16*	2
	{Sangster's No. 1}	17	2½—3
March 1.	{Sangster's No. 1}	18	2½—3
	{Bishop's Longpod	17	3½
March 15.	{Scimitar	18	4
	{Perfection	17	4
April 1.	{Flack's Victory	16	3
April 15.	{Alliance	14	3
May 1.	{Perfection	16	4
May 15.	{ditto	16	3
June 1.	{Hairs' Mammoth	16	3
June 15.	{Prizetaker	14	4
July 1.	{Bishop's Longpod	13	2½—3
	{Eclipse	14	2½—3

All the varieties except Prolific (Dillistone's), which yields its pods together, will continue in bearing for fourteen days, and the late kinds to nearly six weeks. Stick, earthing previously, advancing crops, and in dry weather pour water freely—a drenching twice a-week; but if dribblings can only be given, sprinkle the haulms through a fine-rosed watering-pot. They are sure to be refreshed a little by the operation. Copious waterings prolong the bearing much, and weak guano or manure water is a good stimulant in dry weather, provided enough be given to reach the roots.

When the crop is fit to gather (which is when the Peas are not so young as to be after boiling a hollow inside filled with water, nor so old as to be mealy, but just between the two, and when nicely boiled will melt in the mouth like so much butter), do not pluck the pods off, for a sudden jerk frequently breaks the pea-haulm to the great injury of the remaining pods. A pair of scissors in the hand of the amateur will enable him to gather his Peas without injuring the remaining pods better than can be done with the hand by the initiated. Barren and half-filled pods more frequently are caused by the careless manner in which Peas are gathered than anything else. I have seen a flourishing crop of Peas after the first picking with the haulms broken, wrenched, and twisted about, and heard the owner complain of the weather preventing his Peas filling. When the pea haulm gets bent, to say nothing of broken, well-filled pods need not be looked for.

No good results from allowing pea-haulms to remain on the ground after the crop is gathered, but positive injury. They are an eyesore, and rob the soil of the benefit derived from exposure to the sun and air: therefore, remove all the haulm immediately the whole crop is gathered, and manure, trench, and dig the ground ready for the next crop; but as an amateur mostly pays for his garden ground by the yard instead of, as in the country, by the acre, it behoves him to look well after his fallows, and so keep every inch of ground under crop. I am one of the very few gardeners who contend vegetable-growing ought to pay, and I consider a writer's argument that few gardeners can, or employers expect, or amateurs wish, to make their gardens pay an absurdity. There is the gratification derived from gardening pursuits; but very few employers indeed would have a garden

if it cost more than the produce is worth, and many amateurs purchase their vegetables because they find it more profitable to do so than to grow them. A writer bringing out an idea with a flourish of trumpets in fruit or vegetable matters, and acting on the idea, "nobody expects gardening to pay," not only deceives himself but those who make gardening a profitable recreation.

Few amateurs grow Peas because writers tell them they can purchase them cheaper than they can grow them. I ask those who have been thus influenced to grow Peas but for one year; and if they do not like the Peas of their own growing better, because more sweet, tender, and well-flavoured than those purchased and for half the money, reckoning nothing for passing a few delightful hours in garden pursuits after the busy duties of the shop and office are over, set me down for a bungler. If the vegetables grown do not save the bread loaf, prevent the necessity for physic, place a stumbling-block before the dram and beershop door, and give smiling wives and happy homes, I will on evidence from the mouth of one witness make a public retraction and apology.

The land that we daily see set apart for building-ground lying idle for years, would, if properly fenced in, let readily to artisans and others for garden purposes, and yield good interest to the owner for the little money expended in fencing; whereas, as it is at present, it only forms a playground for the gambler. The difficulty in obtaining garden ground in towns, and the very little encouragement given to the cottage and amateur gardener by horticultural societies, is a great hindrance to town-gardening. Many horticultural societies that were formed to promote and encourage a love for gardening amongst cottagers and amateurs, have been perverted to serve the interest of the gardener. As a gardener, I hold this to be an injustice to those that contribute to the funds, and a direct discouragement to the amateur and cottage gardener. I do not see the propriety of giving £10 for twelve stove and greenhouse plants to be competed for by gentlemen's gardeners and nurserymen by a provincial society whose professed aim is to promote a love for garden recreations amongst the working classes. If those plants are shown as specimens at which the amateur is to aim, I must confess that it is as bad as teaching a child Euclid before he has learnt the alphabet. A few good prizes given by such society for subjects that any amateur can grow as well as gentlemen's gardeners is, no doubt, good; but to get subscriptions under the condition that they are to be applied to the object for which the society was founded, and fully two-thirds of the subscriptions appropriated to be competed for by gentlemen's gardeners, leaving but one-third to be competed for by amateurs and cottagers, is as wanton as it is wrong. I do not wish to hurt any one's feelings, but to give, as a public writer ought, a clear statement of circumstances that hinder or promote the interests of that we all seek—the advancement of horticulture.

Large prizes in any such society not only hinder many amateurs and cottagers for competing, but tend to make the amateur's garden a costly appendage, for he aims at growing things that are totally beyond his means, and so instead of being a blessing it becomes an injury. But these matters are so foreign to Pea-growing that I must leave them until a favourable opportunity offers; still, as they tend to make gardens costly, I wish to put the saddle on the right horse and not on the primrose of garden vegetables. I will endeavour to show that Peas are a paying crop even where land is high-rented.

I have not allowed anything for time and labour, for I consider the time and labour so spent more like pleasure than anything else, and I think that any individual will agree with me that the pleasure derived from gardening is more profitable than the alluring and deceiving delights of the many attractions and temptations in which towns abound.

Dr.	£ s. d.	Cr.	£ s. d.
Good garden ground can hardly be had near large towns under 1d. per yard per annum, and, as the annexed rough sketch will show, 100 yards are taken up with Peas	0 8 4	30 pecks of Peas at 1s. per peck (but where can they be bought for the money?)	1 10 0

Row of Strawberry.

A friend tells me that he used to spend at least 3d. every night, often more, on a friendly glass, and every Saturday night over rather than under a shilling. By chance he took a house with a bit of garden ground attached to it. He had now what he never had before—something to employ his time. Well, he accidentally fell in with an advertising sheet of *THE COTTAGE GARDENER*, and nicely asked the gardener to lend him a copy. He says he read all of it, and found what he wanted—what, when, and how to sow and plant, in Mr. Keane's weekly calendar. Unlike us gardeners, he did not wait until his employer bought him a copy, but ordered one at once. The other side of the picture is soon told. He spent his time and hard-earned money in his garden, learnt to see more beauty in nature than the beer-shop, and spent his evenings at home.

It was uphill work for a time, weeds were troublesome, land was poor; but now, in his own words, "I am a member of the Mechanics' Institute, have a few cocks and hens, a nice profitable garden, a Fern-case made on winter nights, and a little greenhouse." For what? "The money that used to go in drink." And, he added after a pause, "I have a few pounds in the post-office saving's-bank." With this case before me, I will uphold gardening to be a most profitable business. No matter what the crop, I consider it can be cheaper grown than bought. Digression upon digression must continue no longer, and I return to my theme.

One quart of early Peas will sow a row 15 yards long, and of Marrows 20 yards long. It is a bad practice to allow Peas to grow too thickly, but a good plan to sow thick rather than thin; for in one case it is an easy matter to thin, whilst in the other the crop is lost. My advice is, Sow moderately thick in all instances, and so be prepared for the enemies and adverse climate that may thin the crop. Mildew, however, is engendered by allowing the Peas to stand too thickly, and the yield is not so good from thick as from those moderately thin. A small grub very often attacks Peas in the pod; but I am no entomologist, and I only know that the sparrow is the best cure for it. A pod that we think has nothing in it of a hurtful nature the sparrow will open and take the grub out, and because he does this he must be destroyed by the sparrow-club members! Can any entomologist throw light on the cause of old Peas being infested by a small weevil, which completely destroys their vitality? and does the grub in the peapod change to the weevil that destroys the Pea in its dry condition? Information on this subject would, I think, be acceptable to more than one reader of this Journal. Old Peas never ought to be sown; they come up weak, and are more liable to mildew and to be eaten by grubs than new seeds. Steeping Peas in water before sowing we do

not like, for no amount of steeping will cause them to vegetate if sown in dry soil; and, depend upon it, if the Pea seeds required a morass to vegetate in we should find more of the Pea family by the side of swamps than we do. A far better plan than steeping Peas is to water the drills after the Peas are sown, and then cover up, and no amount of drought will then prevent those Peas from germinating.

Before quitting Peas in small gardens I should like to say a few words on another cause that hinders cottagers from growing Peas even in the country—the difficulty in procuring pea-sticks. Although noblemen and gentlemen are liberal in providing allotment gardens for their poor tenants, I must say they are very niggardly—at least their servants are—over a few pea-sticks. I have seen thousands of cords of brushwood lying rotting in the woods, and known every applicant to be denied taking a few by the steward who had control over them. I am firmly persuaded that if our worthy landowners were aware that a few pea-sticks would contribute to the happiness of the cottager they would as freely give them as they do their customary Christmas gifts. We do not ask leave for people to go when they please into game-covers disturbing the game, but that they may be allowed to take a few when the woodman plies his axe.

I speak from experience on this subject; for the first Peas that I ever grew were when I was a lad at home. Very good were they, as everything won with difficulty is. My father could not spare the land—he wanted it for something else; hares and rabbits would eat them, and the land would not grow them. But I set my mind on having them, and I remember my grandfather giving me sixpence to buy a pint of "Poor Man's Profit." I went to York, a distance of seven miles, and asked a nurseryman (Mr. Clarkson, who lived in Fulford Road), to supply me with the famous Poor Man's Profit. He gave me a pint of Blue Prussian for 3d., and I went home and sowed them that night. An old gardener told me to dig-out a trench, and put some manure in as I would for Potatoes, cover with a little soil, and then sow the Peas upon it. In nine days my Peas were up—April-fools-day—and as soot was placed round some Cabbages near, I put some round my Peas. No snail or hare touched them; and hearing some farmers telling what a famous thing guano was for making crops grow, I thought I would try it. My father had a few bags of the best Peruvian, and I just "forgot" to give a Potato-row its due share. This was sprinkled over the Peas, a smart shower afterwards saved the back of the purloiner, and in a few days my Peas were 6 inches high. They wanted sticking, but where were the sticks? In a plantation adjoining were fir-branches enough to stick an acre; but the keeper would not give me any. Every branch and twig had a pheasant's nest under it! A farmer at last gave me leave to cut some willow branches out of his trees. Slasher in hand, I had the branches quick, dressed, put in, and before I had done I fancied the tendrils had begun to twist round them, and the Peas had grown "ever so much." What a fine row and fine bloom had I! And, best of all, that very year my mother's birthday fell on a Sunday (July 11th), when we had a famous boil, and shall I say a treat? No, not one, nor two, but nine pecks from a nine-yard row! Thus I learnt to grow Peas on a small scale, and knowing some of the difficulties under which cottagers labour, I have endeavoured to pave the way for their removal. I shall not be so particular about the other two classes, as it is expected many of those know considerably more than myself. Suffice it to say I noted how to grow them in a twelve-acre field, have sown them in a gentleman's kitchen garden by the half-acre and one-eighth of an acre.—G. A.

(To be continued.)

RIBSTON PIPPIN TREES CANKERING.

IN No. 115, one of your correspondents asks if Apple trees of this excellent sort can be cultivated without that terrible disease, canker. I reply, Yes. My Ribston Pippin and Nonpareil Apple trees, two sorts notoriously addicted to canker, are growing and doing well, without a spot of canker upon them. They were planted seven years ago where they now stand, in a heavy, cold, wet soil, purposely selected, and the only peculiar culture they have received has been taking them up every alternate year in November, cutting-off closely any roots inclined to perpendicular growth, and carefully replanting, spreading all the young roots so as to lie near the surface, and giving to each tree two shovelfuls of manure spread on the surface round the stem. As a dry

season sometimes follows the removal year it is prudent to have your trees alternately removed, so that if six trees are planted three should be moved, say, in 1865 and three in 1866; you will thus have three trees established and three as little liable to being affected by their removal the previous autumn; but this, of course, depends much upon the nature of the soil and the season.—T. R.

THE ROYAL BOTANIC SOCIETY'S SHOW.

JUNE 24TH.

THIS was the last Show for the season at the Regent's Park, and it was fully equal if not superior to any of its predecessors; and the weather being favourable, though giving every token of an approaching thunderstorm, there was a large attendance of visitors. A storm, in fact, did come, but not till the great majority of the company must have reached their homes—then, in some parts round London, flash and peal followed each other in close succession, and the rain fell in torrents.

Stove and Greenhouse Plants constituted a principal feature of the Show, and of these numerous fine collections were exhibited, including most of those which were at Kensington in the previous week. By far the finest was that of date from Mr. Whitebread, gardener to H. Colyer, Esq., of Darford, the plants which he exhibited being equally remarkable for their great size and the abundance and beauty of their flowers. Particularly noticeable among them were *Ixora javanica* and *Pleoma elegans*, both of immense size, and the flowers of the latter, from their fine mauve purple colour, excited general admiration. There was also a remarkably fine *Erica Cavendishii*, though rather past its best as regards flowers. *Polygala Dalmaniana*, *Rondeletia speciosa*, and *Vinca alba rosea* were likewise very fine. Mr. Peed was second; his *Erica Parmentieriana rosea* was a blaze of the deepest rose-coloured bloom; in his *Allamanda grandiflora* was covered with numerous flowers; and, besides these, he had *Ixora salicifolia* and others, which formed part of the fine collection which he previously exhibited. Mr. Green was third; his *Erica obobata* was a splendid specimen, and his *Azalea Extranee* and *Juliana* were densely clothed with bloom. Mr. Baxendine, who was fourth, had in his collection *Camptretum purpureum* and *Bignonia grandiflora*.

In the Nurserymen's Class of ten Messrs. J. & Fraser were first; and here the two *Kalosanthes*, *Angelina* and *punicus*, lent a rosy tinge to the whole of the plants, in which were included a fine *Stephanotis*, and an *Ixora javanica* with some very large heads of flowers. Mr. Outbush, of Barnet, was second; Mr. Rhodes third. In the Amateurs' Class for a like number, Mr. Chilman came in first; included among his plants were *Erica Cavendishii*, fine *Aphelexes*, *Dipladenia cassiniana*, and *Hedera tulipifera*. Mr. Ingram, gardener to J. J. Blandy, Esq., Reading, was second, having *Hemantthus punicus*, the yellow scarlet flower-heads of which were striking; his *Pinelea mirabilis* and *Rhynchospermum jasmimoides* were also fine. In collections of six the first prize was gained by Mr. Page.

Plants remarkable for their foliage were contributed by Mr. May, gardener to T. P. W. Butt, Esq., of Arle Court, Cheltenham, who had the same immense specimens shown last week; by Mr. Hutt, of Highgate, among whose plants were a magnificent *Dicksonia antarctica*, a large *Latania borbonica*, *Alsophila australis* very large and fine, *Rhopala corcovadensis*, and *Alcacia metallica*; and by Mr. Taylor, of Highgate, in whose collection were *Dion edule*, *Encephalartos latifrons*, *Chamaecrops humilis*, and *Cycas revoluta*. Mr. Wheeler had likewise an excellent collection.

In the Nurserymen's Class for the same description of plants, remarkably fine collections came from Messrs. A. Henderson and Co., and Mr. Bull. The former had *Alcacia macrorrhiza variegata*, *Jacaranda filicifolia*, *Croton variegatum pictum* and *angustifolium*, *Caladium Chantini*, *Dracena ferrea*, *Maranta variegata*, and some others, whilst Mr. Bull had a *Rhopala corcovadensis* which reached to the top of the tent; *Tubianthus calyptratus*, also of very large size; *Araucaria Bidwillii*, *Pandanus javanicus variegatus*, *Hippomane longifolia*, *Areca rubra*, *Latania borbonica*, and *Yucca aloifolia variegata*. The plants in both collections, it is almost unnecessary to remark, were of large size, and without exception in excellent condition.

Cape Heaths were shown in abundance and great beauty, some of the most conspicuous being *Bergiana*, naturally a free-flowering kind; *ventricosa superba*, *grandiflora*, *Bothwelliana*, and *magnifica*; *Aitoniana turgrida* and *Turnbulli*, *Messoni*, *nobilis*, *obobata*, *Candolleana*, *Spenceriana*, and *metuliflora bicolor*.

Messrs. Jackson & Son were first in the Nurserymen's Class for ten, Mr. Rhodes second; and in the Classes for eight and six plants, first prizes were awarded to Mr. Peed and Mr. Chilman, and second to Mr. Page and Mr. Ingram.

In Orchids, of which there was a good display, there was nothing in the various collections much different from what has been previously noticed.

In collections of twenty, Mr. Baker was first, and Mr. Milford second, the latter having an extremely fine *Vanda tricolor superba*, and *Cypripedium villosum*, also fine; and in twelve Mr. Penny and Mr. Woolley had first, and Mr. Green and Mr. Page second prizes.

Of Ferns, excellent collections both of exotic and British were shown by Mr. Lavey, of Fetcham, and of the former by Mr. Bull, and Messrs. A. Henderson, the plants in the last two exhibitions being the same as those noticed last week as being shown at Kensington. Messrs. Ivory and Miss Clarkson had also collections of hardy Ferns. Some fine pans of *Lycopods* were likewise shown by Mr. Lavey, and by Mr. Young, of Highgate.

Euchais were exhibited by Mr. Gardener, of Clapham Park, Mr. Cannell, Mr. Green, and Mr. Weston, who received prizes in the order in which their names stand. Mr. Gardener had Senator, Madame Cornelissen, Prince Imperial, Rose of Castille, Isa Craig, and Fair Oriana, all of which were handsomely grown, and in fine bloom.

Mr. Cannell's plants were—Always Ready, Reine Blanche, Prince Alfred, Lord Elcho, Schiller, and Madame Cornelissen. Mr. Green's were larger but not so compact, and among them were *Souvenir de Chiswick*, *White Lady*, *Lord Clyde*, and *Masterpiece*.

Pelargoniums both Show and Fancy varieties were of surpassing excellence. The best in the Nurserymen's Class of twelve were from Mr. Turner, of Slough, the kinds being *The Belle*, *Ostris*, *Marie*, *Bijou*, *Glowworm*, *Bacchus*, *Ariel*, *Nestor*, *Viola*, *William Bull* (a glowing carmine), *Perdita*, and *Spotted Gem*. Messrs. Fraser were second.

In the Amateurs' Class of ten nothing could be finer than the plants exhibited by Mr. Nye, gardener to Miss Foster, at Clewer, and which consisted of *The Belle*, *Ariel*, *Ursula*, *Golden Hue* (splendid), *Perdita*, *Viola*, *Empress Eugénie*, *Eastern Beauty*, *Bacchus*, and *Matilda*. Mr. Wiggins, gardener to W. Beck Esq., Isleworth, was second with some nice plants.

In Fancies, Mr. Turner and Messrs. Fraser were equal first in the Nurserymen's Class. The kinds shown by the former were *Cloth of Silver*, *Delicatum*, *Sarah Turner*, *Cheerfulness*, and *Claudiana*, all of them splendid plants; whilst Messrs. Frasers' were *Delicatum*, *Cloth of Silver*, *Acme*, *Bridesmaid*, *Marionette*, and *Arabella Goddard*. In the Amateurs' Class Mr. Bailey, of Shardeloes, was first with *Crystal Beauty*, *Negro*, *Lady Craven*, *Arabella Goddard*, *Rosabella*, and *Musjid*, all of which were exceedingly fine; as were also those from Mr. Shrimpton, who was second.

Prizes were offered for Pelargoniums, the test merit in which was to be health, large size, and abundance of bloom, and the highest award was made to Mr. Nye, gardener to Miss Foster, for truly magnificent plants, some of which could not be less than 4 feet across. They were *Viola*, *Desdemona*, *Sanspareil*, *Bracelet*, *Fairest of the Fair*, and *Sir C. Campbell*. Some large and well-grown plants of *Scarlet kinds* were also shown, as well as several collections of Pelargoniums sent out in the autumn of 1861, or since, in which Mr. Turner was first, Messrs. Fraser second, and Mr. Wiggins third. Mr. Turner's were *Novelty*, *Fair Rosamond*, *Royal Albert*, *Timon*, *Celeste*, and *Lord Chancellor*.

Cut Flowers, principally Roses, constituted an exhibition of themselves. For fifty Roses, Mr. Turner had first prize for a splendid collection, awards being also made to Mr. Mitchell, of Piletdown Nurseries, and Messrs. Paul & Son. Miss Crawshaw, of Caversham Park; Mr. Terry, of Youngsbury; Mr. Turner; Mr. Hollingworth, of Maidstone; and Messrs. Paul and Son were likewise successful exhibitors in other classes; and Mr. Francis, of Hertford, with pot Roses on the *Manetti* stock. Pinks were shown by Messrs. Turner, Bragg, Parker of Walthamstow, and Hooper of Bath; Pansies by Messrs. Downie, Laird, & Laing, Bragg, August, Fraser of Edinburgh, and others. There was likewise a good show of *Verbenas* from Mr. Turner, Messrs. Perkins, and Mr. Perry of Castle Bromwich. Messrs. Barr & Sugden had *Iris*, early *Gladioli*, and *Ixia*. Some *Sweet Williams* were also staged.

Among Miscellaneous Plants, many new ones were exhibited which have been already noticed in our columns, such as Messrs. Veitch's handsome *Cyanophyllum*-like *Spharogynis latifolia*, *Miconia pulverulenta*, and the blotched-stemmed *Alocasia zebrina*. They had besides a new and very ornamental *Escallonia* from Chili, of free-flowering habit, and which may prove hardy; also, the new Ferns *Selliguea pithiifolia*, and *Alsophila Tenaxis denticulata*, a crested form of *Pteris serrulata*, a hybrid *Cattleya* between *Loddigesi* and *Acklandiae*, *Paneratium amboinense*, the variegated *Rhynchospermum*, &c. Mr. Williams, of Holloway, had a collection of fine-foliated and new plants, in which were *Cibotium Schiedei*, *Gleichenia semivestita*, *Agave filifera*, *Pandanus reflexus*, and *Guzmania picta*; also, his new *Cyrtopodium Stonei*. Mr. Bull contributed the handsome new *Athyrium filix-femina diffusum*, *Centaurea argentea*, the Golden-powdered *Gymnogramma Lauchiana*, *Latania Verschaffelti*, *Sparkler*, and other new *Mimulus*; also, his new *Pelargonium* and *Petunias*.

Messrs. Low & Co. had the handsome *Alocasia Lowii*, also *Dendrobium Parishii* and *nodatum*; Messrs. Ivory & Son, *Athyrium filix-femina glomeratum*; Messrs. Carter, Snowball *Geranium*, white; Mr. Turner, *Bougainvillea*; Messrs. Henderson, *Mimulus*, *Centaurea argentea*, and an interesting collection of *Ivies*; and Mr. Standish, his beautiful new *Deutzia*, *Lychnis Senno*, and other new Japanese plants.

FRUIT.

The exhibition of Fruit was very extensive and generally excellent. Pines were both numerous and of large size; and of Peaches and Nectarines there were many remarkably fine exhibitions besides those which received awards. The most defective part of the Fruit Show was the collections, not one of which was up to the mark.

Mr. Kuffert, gardener to Lord Palmerston, was first with Black Hamburg and Muscat Grapes, a Melon, a Pine, Elruge Nectarines, Galande Peaches, and Lee's Perpetual Figs. Mr. Henderson, of Trentham, was second with four Pines, Trentham Black and Buckland Sweetwater Grapes, two Melons, Royal George and Violette Hâtive Peaches, Violette Hâtive Nectarines, Circassian Cherries, Brown Turkey Figs, and some inferior Strawberries. Mr. Young, of Havart; Mr. Masters, of Sherburn Castle; and Mr. Turnbull, of Blenheim, were the only other competitors.

Of Figs, excellent collections of four and more fruits were shown by Mr. Young, of Aberaman, and Mr. Bailey, of Sharncliffe, among which were two Providences, from Mr. Young, of 9 lbs. 6 ozs. and 8 lbs. 11 ozs. respectively, and several Queens weighing more than 4 lbs. In Providences, Mr. Young had an immense fruit of 11 lbs. 6 ozs., but which being over-ripe had to be passed over in favour of one weighing 8 lbs. 3 ozs. from Mr. Cawhill, of Tickhill. Mr. M. Henderson, of Coleorton Hall, had one of 7½ lbs., which stood next on the prize list; and Mr. Muggleton, gardener to W. Cubit, Esq., Andover, had also a fine fruit. Mr. Hall, gardener to Lord Scarborough, had five fine Queens, one of which weighed 4 lbs. 11 ozs.; Mr. Smith, of Norwood Grove, one of 4½ lbs. Fine fruit of the same kind were likewise shown by Mr. Moore, of Redland Lodge, Bristol, and Mr. Young, of Aberaman, the latter having also an Enville of 7 lbs.; whilst Mr. Bailey had Prickly Cayennes, an Enville, and Lemon Queen; Mr. Chalmers of Drayton Manor, a fine Moscow Queen; and Mr. Taylor, of Temple Newsum, a very good Black Prince.

Melons were extensively shown, and both as regards appearance and, we believe, flavour, were excellent. The best in the Green-fleshed class was a hybrid Persian from Mr. Meredith, of Garston; King's Green-flesh from Mr. Tegg, was second; and in Scarlet-fleshed kinds Mr. Chilman had first prize; the second being awarded to Mr. Mounsden, of Moreton Hall, Congleton, for a kind called Moreton Hall.

The display of Grapes was not only large, but of great excellence. In three dishes of distinct varieties by far the finest were those from Mr. Hill, of Keble Hall, which had Buckland Sweetwater, Black Hamburg, and Black Prince; all were fine, but the bunches of Black Prince were magnificent, the finest of the three was not less than 20 inches in length, compact, even in size of berries, perfect in colouring, and covered with a beautiful bloom. Their weight was 9 lbs. 5 ozs. Mr. Henderson, of Trentham, was next with Black Hamburg, Victoria Hamburg (very fine), and Buckland Sweetwater. Mr. Peachy had Grizzly Frontignan, and Golden and Black Hamburg.

Several baskets were exhibited, the best being Black Hamburg from Mr. Meredith, weight 16 lbs.; the same kind, also very fine, from Mr. Hill, and Bailey's Muscadine from Mr. Bailey.

In Black Hamburgs, three bunches, Mr. Meredith was again first with splendid bunches and berries; and for Black Prince Mr. Hill had the highest prize for three bunches weighing 7 lbs. 12 ozs., and equally fine in appearance with those already noticed. For Muscats Mr. Turner had the first prize, the bunches and berries though fine were not ripe enough; and Mr. Turnbull, Mr. Embray, and Mr. Clements had also good exhibitions.

In the Any variety class, Mr. Hill had very fine bunches of Buckland Sweetwater, the three weighing 6 lbs., for which he had the first prize; Mr. Drewett, Chasselas Musqué; Mr. Peachy, White Frontignan; Mr. M. Henderson, Grizzly Frontignan; Mr. Smith, Norwood, Golden Hamburg; and Mr. Constantine, Chavoush. Fine but unripe bunches of the Black Alicante were also shown by Mr. Petch.

Peaches and Nectarines, as already observed, were extremely fine, and to particularise all that were worthy of notice would occupy more space than we can afford. Mr. Dawson, gardener to Earl Cowper, Panshanger, had Downton and Hunt's Tawny Nectarines, and Violette Hâtive and Galande Peaches, all of which were very fine. He received a first prize, the second going to Mr. Turner, of Slough. In two dishes, one of Nectarines and one of Peaches, the best came from Mr. Wills, of Oulton Park, consisting of Royal George Peach and Elruge Nectarine, both very large and perfection in ripening. Mr. Constantine, of Hillingdon Court, was second for Royal George Peach and Violette Hâtive Nectarine, which were also very large and fine.

Of other fruits, good Figs were exhibited by Mr. Smith, of Syon; Cherries, by Mr. Snow, who had Elton and Circassian, and by Mr. Turner, who had the latter kind; and Strawberries, by Mr. Widdowson, who had fine dishes of Empress Eugénie, Admiral Dundas, Sir C. Napier, and Sir Harry. Some excellent Vines in pots were shown by Mr. Stone, Mr. Young, of Highgate, and Mr. Humby, of Brentford; those of Mr. Stone in particular being very fine, and bearing good-sized bunches. Lastly, Messrs. Fraser had Peaches and Pears, and Messrs. Lane & Son Figs, Cherries, Apples, Pears, and Plums in pots.

PREPARING STRAWBERRY PLANTS FOR FORCING.

I INTEND potting some Strawberry plants from runners. Is it better to do so in small pots and repot into six-inch pots in the spring, or strike them from runners into six-inch pots at once, as the latter would save trouble if there is no disadvantage?—A. Z.

[Both modes are good in proportion to the management. We frequently ourselves take off the runners as soon as made, and the roots are shown in embryo, and plant about 3½ inches apart in light soil above a slight hotbed, and as soon as they form roots and balls, lift them and pot in six or seven-inch pots. Owing to the dry weather our runners are scarcely fit for using any way as yet, but in a week we hope they will be so. Of the two modes suggested by you—layering in a small pot, or layering in a large one at once, we prefer the first mode, and on the whole we do not think we incur more trouble or labour, whilst we think we obtain some advantages. By the small-pot process at first there is little primary care needed, whilst by potting at once in large pots much care in preparing the pots is necessary, if good success is to be obtained; and there is a great trouble in wheeling to and rewheeling from a quarter 32 or 24-sized pots instead of 60's.

Our general process is to take a barrow nearly filled with light loam and leaf mould, and the top filled with large 60 or 54-sized pots to the Strawberry-quarter, put a crock in the pot, fill with soil, and fasten the layer in the middle of the pot either with the fingers or by placing a pebble or good-sized crock over it. These fairly watered will soon fill the pots with roots, and when that is done the runner is cut, and the pots and plants wheeled to a shady place for a few days, in order that by watering and syringing they may get over the partial check of being severed from the runner. Then they are finally potted, using rather stiff rich loam, and placing the plant so that the bud shall be at least as high as the rim of the pot, and potting as firmly as fingers and

a wood rammer can make the soil. The two advantages of this plan are—first, the security that the bud or centre of the plant shall not be too much sunk, as in that case the plant will rarely fruit well; and, secondly, the making sure that the pot all through will be filled with fine fibry roots, so that the whole ball shall be matted with them; and thus the second potting disconcerts a natural tendency of the plant to send its roots at once to the sides of the pot, and to cluster there while the centre of the ball is comparatively free from fibres.

By the second mode—putting the runner at once in the fruiting-pot, there will be as much care required as in the second potting by the above mode, and thus at least at first and in the busiest season more of first trouble will be necessary. True, we have seen thousands so done without much trouble. The pots (large 32's) were taken to the place and drained, the plant placed on the surface of the soil, growing well, making fine foliage, and moved some time in autumn, with the runner a rather nice plant sunk down an inch or two or more below the rim of the pot, and all looked nice, though we seldom heard much of their wonderful fruitfulness. The mode by which we have succeeded best by the at-once-layering in the fruiting-pot, is as follows:—The pot was suitably drained, a little moss and soot placed over the drainage, and the soil packed in firmly, leaving a small cone a little loose on the surface for the runner, that cone being from half an inch to an inch above the rim of the pot, for before autumn the soil would have sunk, perhaps, half an inch below it. So treated these plants did well, though not better or hardly so well as those laid in small pots and again repotted. Our chief reason for not following the plan often is, the much greater time and trouble it takes for securing rooted plants in the first instance, and that at a season of the year when it is a serious question to decide what should be done first. By the period the layers need repotting we generally have a little more breathing time. If our correspondent "A. Z." decides on the layering in the fruiting-pot at once, we would draw his attention to the above conditions; if he layers in a pot filled lightly with soil, we would not hold out great hopes of a fine crop. We have seen hundreds of instances in which such quick work was done, and other more tedious processes decried, but we have heard few boastings at gathering-time under such circumstances, and especially if the fruit was wanted at all early.—R. FISH.]

CRYSTAL PALACE ROSE SHOW.—JUNE 27.

If any doubt could have existed as to the increased and increasing popularity of the queen of flowers, such doubts would have been inevitably removed at the sight which the frequenters of the Crystal Palace were permitted to witness. Whether one looked at the vast number of entries, especially amongst amateurs, amounting in some of the classes to upwards of thirty stands, or the immense crowd of people assembled to see them, it must surely be conceded that no flower is so universally admired or more widely grown than the Rose. And notwithstanding the awful thunderstorm which swept over the south and east of England on Wednesday night, shattering the hopes and the Roses of many an exhibitor (for many who had given notice were unable in consequence to attend), and severely injuring others that were exhibitors, I think one can safely say that, although there have been years when many much finer Roses have been exhibited, yet on the whole the collections were in fair average condition, while some of the blooms were of surpassing excellence. The backwardness of the season, too, was against them; for although we have had almost forcing weather for the last ten days, yet until then Roses were in some districts not in bloom. My esteemed friend, Mr. Hole, told me on the 17th he had not any in bloom save Gloire de Dijon; and Mr. Paul of Cheshunt, and Mr. Francis of Hertford, both complained to-day of the backwardness of their flowers; it was, however, a most grand display, and their fragrance, freshness, and beauty well merited the superiority of her floral majesty.

Amongst the first questions asked at a Rose show is, Which is the best new Rose? and hence the boxes of new flowers of 1861 and 1862 first claim a notice. There were, from whatever cause, not any finely exhibited. There were only three stands, and in one of them hardly a new Rose of last autumn was to be seen. The same causes which affected the general aspect of the Show may have been at work here, and we may, perhaps, look to see them better a little later. The first prize was awarded to Messrs. Paul & Son of the Old Nurseries, Cheshunt, for Peter Law-

son (1862), a new Rose of promise; Souvenir de M. Rousseau; Wilhelm Pfitzer; Turenne, very bright; Duchesse d'Alençon, worthless; Lord Clyde (1862), a splendid bloom with fine foliage, decidedly the best new Rose exhibited there; Monte Christo; Louise Darzins, very white, but wants the substance of Mdle. Bonnaire; Paul Feval; Etienne Lecrosnier; Archevêque de Paris; Madame Caillat, bright, but thin; Prince Camille de Rohan, very dark, good; Gloire de Chatillon, will not do; Maurice Bernhardt, a fine Rose; Madame Helye, bright; Olivier Delhomme, very good; Professor Koch, double and good; Maréchal Vaillant, very bright; Souvenir de Comte Cavour (Margottin), very fine; Richard Smith; Vulcain, slaty; Le Rhone (1862), promises to be one of the best of the new Roses; Jean Gousson (1862); Triomphe de Caen; Beauty of Waltham, a fine Rose but soon flies; Princesse d'Orleans; Madame Charles Wood, a bright, large, and good Rose. Mr. William Paul was second, with Charles Lefebvre, good; Triomphe de Caen; Turenne; Madame Caillat; Wilhelm Pfitzer; Duc de Rohan, good; John Cranston (Moss); Gloire de Chatillon; Christian Püttner, good; Souvenir de Lady Eardley, good, but not in character; Emile Dulac, pretty imbricated Rose; Professor Koch; Seedling Mdle. Emain; François Lacharme, very fine and good, one of the best of the Roses of 1861; Reynolds Hole, bright pink; Vulcain; Comtesse de Seguier; Prince Camille de Rohan; André Desportes, good; Souvenir de Comte Cavour; Beauty of Waltham. Mr. Standish was third, with Madame Charles Wood; André Leroy (1862), good; Madame Standish; Mrs. Dombrain (1862); Vulcain; Vicomte Vigier; Turenne; André Desportes; Grégoire Bourdillon; J. F. Lombard (1862); Madame Boutin, Reynolds Hole, and Souvenir de Comte Cavour.

It is, I believe, hardly worth while to give in so large a number as ninety-six varieties the names of the flowers in each winning-stand. I believe that while the best flowers are generally selected for these stands, the more generally useful ones are in those of smaller numbers. I shall, therefore, simply give the names of the most remarkable flowers in the two winning-stands. The first prize was awarded to Mr. J. Mitchell, of Pitdown Nurseries, near Uckfield, Sussex, and amongst his flowers I particularly noticed Prince Imperial, Duc d'Ossuna, Madame Caillat, Madame Charles Crapelet (a beautiful bloom), Souvenir de Comte Cavour, Evêque de Nîmes, Catherine Guillot, General Washington (a beautiful bloom), Homère (a fine Tea), Paul Ricaut, Louis XIV, Sénateur Vaisse, Triomphe de Rennes, Général Jacqueminot, Gloire de Dijon, Souvenir de la Malmaison (very good), Peter Lawson, Comtesse de Chabillant, and W. Paul (1863, a very promising Rose). Mr. C. Turner, of Slough, was second. His best blooms were Paul Ricaut, Baron Gonella, La Brillante (very fine), Souvenir de l'Elise, Madame Willermoz, Jules Margottin, Professor Koch, Narcisse, Anna de Diesbach, Niphotos (a splendid bloom), Madame Charles Crapelet, Céline Forestier, Madame Furtado (excellent), Souvenir de Comte Cavour (a wonderful bloom), Louis XIV (very fine), Darzins, Coupe d'Hébé, Mrs. Rivers, Vicomte Vigier, François Arago, and François Lacharme.

In Class 2, forty-eight varieties, three trusses of each, the first prize was awarded to Mr. B. R. Cant, of Colchester, for Mathurin Regnier, Grégoire Bourdillon, Jules Margottin, Madame Willermoz, Souvenir d'un Ami, Olivier Delhomme, Eugène Appert, Comte de Paris, Baronne Prevost, Comte de Falloux, Général Jacqueminot, Comtesse de Chabillant, Pauline Lanzezeur, Adam, Victor Verdier, Madame Bravy (fine Tea), François Lacharme, Orderic Vital, Lord Raglan, Wm. Griffith, Charles Lawson, Souvenir de M. Rousseau, Sénateur Vaisse, Mrs. Rivers, Anna de Diesbach, Duchess of Norfolk, Monte Christo, Bougère, Rubens (a very fine Tea, exhibited in several stands to-day), Duke of Cambridge, Lælia, Madame Boll, Victor Trouillard, Madame Knorr, François I., Madame Domage, Paul Ricaut, Modèle de Perfection, Devoniensis, Empereur Napoléon, Triomphe de Lyon, Souvenir de Comte Cavour, and C. Lefebvre (very fine).

Mr. Charles Turner, of Slough, was second, with Général Jacqueminot, Comtesse de Chabillant, Gloire de Dijon, La Ville de St. Denis, Madame Charles Wood, Baronne Prevost, Géant des Batailles, Madame Vidot, Eugène Appert, Souvenir de Comte Cavour, Madame Bravy, Jules Margottin, Madame Guinnoisseau, Devoniensis, Alphonse Damazin, Triomphe de Rennes, Anna Alexieff, Catherine Guillot, François Arago, Victor Verdier, Louis XIV., Vicomte Vigier, Coupe d'Hébé, Madame de Cambacères, Souvenir d'un Ami, La Brillante, Duchess d'Orleans, Madame Knorr, Jean Bart, Evêque de Nîmes, Madame C. Crapelet, Céline Forestier, Modèle de Perfection.

tion, Paul Ricaut, Lord Raglan, Mathurin Regnier, Narcisse, La Reine, Senateur Vaisse, Wm. Griffith, Buffon, La Fontaine.

In Class 3, twenty-four blooms, three trusses of each, Mr. Francis, of Hertford, was first with Colonel de Rougemont, Jules Margottin, Eugène Appert, Mademoiselle Bonnaire, Louis XIV., Madame Boll, Anna de Diesbach, Général Jacqueminot, Charles Lawson, Souvenir de la Malmaison, La Reine, Catherine Guillot, Anna Alexieff, Mrs. Rivers, Senateur Vaisse, Victor Verdier, Wm. Griffith, Paul Perras, Paul Ricaut, Gloire de Dijon, Lord Raglan, Baronne Prevost, Géant des Batailles. Messrs. Paul & Son were second with Paul Perras, Senateur Vaisse, Victor Verdier, Parmentier, Mathurin Regnier, Triomphe des Beaux Arts, Madame Caillat, Triomphe de Paris, Anna Alexieff, Lord Clyde, Général Jacqueminot, Mdle. Bonnaire, Général Castellane, Transon Goubault, Jules Margottin, Madame Charles Wood, Madame Boll, La Ville de St. Denis, Comtesse de Barbanne.

In Class 4, twenty-four varieties, one of each, Mr. W. H. Treen, of Rugby, took first with Baronne Prevost, Général Jacqueminot, Louis Buonaparte, Anna Alexieff, Paul Ricaut, Lord Raglan, Brennus, Lanei (Moss), Madame Helye, Mrs. Rivers, Senateur Vaisse, Coupe d'Hébé, Sidonie, Gloire de Dijon, Eugène Appert, Jules Margottin, Charles Lawson, Reynolds Hôle, Empereur de Maroc. Mr. C. Turner took first in twelves.

I must pass on to the Amateurs, who came out nobly, both as to the number and blooms, Mr. Hedge, of Colchester, still bearing all before him, obtaining three first prizes and one third with some excellent flowers, but on the whole not quite up to what he had last year. Of the thirty-six varieties I have no note, but in twenty-fours he had Comtesse de Chabillant, Madame Vidot, Rubens, Madame de Cambacères, Leo X., Comtesse de Kergorlay, Madame Boll, Triomphe de Lyon (Tea), Madame Maason, Coupe d'Hébé, Senateur Vaisse, Mrs. Rivers, John Hopper, Gloire de Dijon, La Reine, L'Enfant Trouvé (grand), Paul Ricaut, Letitia, Lord Raglan, Jules Margottin, and Cynthée.

In Class 8, Mr. Hedge was again first with Comtesse de Chabillant, Madame Vidot, Charles Lawson, Adam (very fine), Madame de Cambacères, Souvenir d'un Ami, Boula de Nanteuil, L'Enfant Trouvé, Jules Margottin, Mrs. Rivers, Madame Maason, Rubens, Madame Boll, Gloire de Dijon, Lord Raglan, La Fontaine, William Griffiths, and Madame Sertot, Mr. Ingle, gardener to C. G. Round, Esq., of Colchester, was second, with Pauline Lanzeur, Devonians, Col. de Rougemont, Jules Margottin, Anna Alexieff, Elise Sauvage, William Griffiths, Gloire de Dijon, Prince Léon, Imperatrice Eugénie, Eugène Appert, Madame Furtado (splendid), Baronne Prevost, Général Jacqueminot, Souvenir de la Malmaison, and Comtesse de Chabillant.

In Class 9, twelve blooms, the first prize was obtained by a new competitor, Rev. V. Knox Child, of Dunmow, with Madame Knorr, Madame C. Crapelet, Victor Verdier, Napoléon, Comtesse de Chabillant, Senateur Vaisse, Souvenir de la Malmaison, Jules Margottin, Gloire de Dijon, Général Jacqueminot, and Triomphe de Lyon. The second by Mr. Pullinger, gardener to F. G. Wilkins, Esq., Leyton, with Louis XIV., Gloire de Dijon, Madame Boll, Madame Guinnoisseau, Madame Bravy, Comtesse de Chabillant, Madame Rivers, Senateur Vaisse, Victor Verdier, Gén. Jacqueminot, Baronne Prevost, and Turenne.

There were several objects of interest, but my hand tires and my head wears, and so, with many a pleasing thought of a hard day's work, I must draw to a close. I cannot do so without again saying that the comfort of all concerned was amply provided for by the Company, and that the indefatigable exertions and constant courtesy of Mr. Houghton, were again rewarded by a most brilliant and successful Show.—D., *Deal*.

Prizes were offered in Class 11 for thirty trusses arranged for table decoration; Mr. Turner, Mr. Hedge, and Mr. Cranwell, Penge, were the successful prizetakers. However Roses are employed for decorative purposes, the effect is seldom otherwise than pleasing, and these arrangements certainly were so; but though the stands varied considerably in character, there seemed to be too much of sameness in the mode in which the flowers themselves were disposed.

In Class 12, Mr. W. Paul had the first prize for twelve varieties of pot Roses in large pots. Among them were included magnificent plants of Lælia, La Reine, Madame de St. Joseph, Gloire de Dijon, Coupe d'Hébé, and other kinds which that distinguished cultivator has so successfully exhibited this season.

In the next, Class 13, for twenty-five Roses in eight-inch pots,

he had also first prize, a similar award being made to Messrs. Paul & Son; and a second prize to Mr. Turner.

Some miscellaneous objects were also shown, among which were included a Cucumber, called Paul's Emperor, from Mr. W. Paul; fruit trees in pots from Messrs. Lane; Irises from Messrs. Barr & Sugden and Butler & McCulloch; double dwarf Poppies, which might easily be mistaken for Hollyhocks, from Hooper and Co.; also a fine stand of Pinks from the same. Messrs. F. & A. Smith had in addition Fuchsia Pillar of Gold, with yellow variegated foliage; Messrs. Downie, Laird, & Laing, Antirrhinums, Pansies, seedling Phloxes, &c.; and a Japanese flax for tying purposes came from Mr. Allison, of Laurence Pountney Lane, City.

PRUNING AND MANURING ROSE TREES.

SOME time ago Mr. Beaton gave your readers some advice respecting the treatment of Roses raised from cuttings, which he said should be cut down in the June after they were planted out, to encourage the growth of one or more strong shoots from near the ground. I have already tried this advice on half-a-dozen plants, and with complete success so far, for they have thrown-out very strong shoots, some from 8 to 10 inches long, and very robust.

Now, I want to know how I am to treat them when they are full grown. I suppose they are to be headed-down, but at what height, and whether are they to be trained as standards or as bushes?

May I also ask what manure is best for Roses where neither stable nor farmyard manure is available? I am in the habit of collecting all the weeds, leaves, stalks and other vegetable refuse of my garden, and mixing it with lime: would this suit Roses? Would it be improved by the addition of a little salt? My soil is a stiff loam on yellow clay.—S. M.

[You do not say what your Roses are—Perpetuals, Bourbons, Chinas, or Teas. Mr. Beaton intended Rose trees from cuttings to be treated as dwarfs; for we never knew him recommending any one to put Roses on stilts, as is the fashion now-a-days. He always advocated that there was no stock good enough for the queen of flowers, nor any root so likely to feed it as its own.

Presuming your Roses are Perpetuals, you must cut a strong shoot down to five eyes, and a weak one to three, always cutting very weak shoots close off. You must not allow any shoot to overlap another; keep the centre of the tree somewhat open, and so arrange the shoots that next year's growth will form a compact bush. In future years the shoots may be cut down to a couple of eyes, or if you want size, to five or six. If you would prefer a pyramid, and they are handsomer than standards, choose a strong shoot in the centre of the tree, and if the tree has three or more shoots over and above the centre shoot cut them to six eyes each, and the centre one to four. All this pruning should be done as soon as the trees are leafless or from that to the middle of March. In July stop the centre shoot and the side shoots from the leader of the previous year to six leaves; but the lower shoots must not be stopped at all—they cannot be too vigorous, yet as you will have six shoots on each branch, reduce them to three, taking away the two lowest and every other afterwards. Should the leader break strongly after stopping, stop it again at the fourth joint, and so on. In the autumn you will have the basis of a pyramid, and you will then prune the centre shoot or leader to eight eyes, take three of them away in spring, and stop the leader the same as the year before, so as to encourage the side shoots to make good wood. All the other shoots should be cut to two or three eyes according to their strength, taking care to prevent crowding, and to admit plenty of light and air into the centre of the tree.

If you are anxious to have a standard, put a stake to one of the strongest shoots, removing all the others, and let it grow to the required height and as much longer as it may the first season. Cut the shoot down to the required height at pruning time, and in spring disbud the stem, taking away all the shoots except three at the top, or five at the most may be left. In summer stop any shoot that is more rampant than its neighbours, and in winter prune to five eyes the first, three the second season, and so on, always pruning so that a compact head will be formed. Standard Roses on their own roots would be quite a novelty, and if they are longer-lived than those on the Dog Rose it will prove a fact in gardening (as yet but asserted) worth knowing. After all your Roses may be Bourbons, but if they are the treatment recommended for Perpetuals

will suit them; strong growers of either require moderate, and weak growers close, pruning. China Roses do not require much pruning, but a thinning or regulating of the shoots. Teas, too, do not like the knife; they flower better with moderate than close pruning.

Under the circumstances we do not think you could have a better dressing for your Roses than decayed vegetable matter; a little Peruvian guano sprinkled around the trees in March would do them no harm; it would be washed down to the roots with the first strong shower, and they would not be long before they showed its effects. We never use salt, and we should be cautious about doing so. A little might do no harm, but we think anything like a large quantity would be hurtful.]

MIMULUS CUPREUS.

THIS recently imported plant is a gem in the class to which it belongs—an acquisition for small greenhouse and conservatory decoration. Let its bedding properties be what they may, owing to its slender and somewhat delicate habit I fear it would not stand well out of doors in this part of Ireland, although we have moisture enough, if that is of any advantage; and I likewise fear it will not be found to stand well in the south, if the seasons prove at all dry, for the *Mimulus*, delighting in plenty of moisture, nothing suffers so quickly from drought. Its cultivation is simple enough. Seed if sown in February and carefully attended to, will produce blooming plants by May. I purchased a packet of seed from a London house. The plants are now beautifully in bloom and promise to remain so for some length of time.

The three new kinds, crosses from *cupreus*, figured in last month's "Florist and Pomologist," without doubt are pretty; but in my opinion fall far short of the original, for which we have to thank the Messrs. Veitch.—JOHN EDLINGTON, *Crom Castle*.

DESTROYING INSECTS—DEODORISING.

RECENTLY you stated that soot (half a peck to twenty gallons of water), is good to wash trees and plants infested with insects. Do you prefer it to tobacco water? and does the latter, or Gishurst compound, or Neal's plant soap, injure the foliage or flowers of plants, as Geraniums, Calceolarias, &c., on which it falls? and can you recommend a wash to syringe Roses covered with green fly that would be effective and not injure the foliage and flowers beneath them?

Would a little chloride of lime take away the smell from liquid manure for in-door use? And if so what proportion should be put to a gallon and not to injure the plants?—H. G.

[The greater our experience the more fully are we convinced that the man who discovers any effective wash that will destroy all insects, and yet be perfectly harmless to plants, may soon, if he chooses, be able to ride in a coach and six, and have a mansion and establishment to match with such external grandeur. We have also proved repeatedly that what will destroy insects at one time will not do them much injury at another time, and hence the importance of not relying upon any one specific. Hence also the importance of using liquids which are distasteful to insects, and which will rather tend to increase the vigour of the plant than otherwise. Soot water of the strength mentioned above will not kill insects so effectually as tobacco water, if it be strong enough to kill at once, but it will be as effectual as very weak tobacco water. Our own experience tells us that tobacco water, strong enough to kill the insects at once, will also injure the shoots and foliage, and so with all the other things named—Gishurst and the rest of them. Careful people, therefore, prefer weaker doses repeated instead of a strong dose at once. We have cleared many Rose bushes of green fly with clear soot and lime water alone, and left no marks on the plants beneath them, and this could hardly be said of Gishurst or tobacco water. We have, moreover, seen days taken in dipping and washing shoots of Roses in tobacco and other waters, and the leaves getting almost as much injured as the insects; when the same time would have enabled a person to run his fingers along the shoots, crush all that came in his way, and then wash off all the remains either with clear soot water or clear soft water.

There is this objection to all washings—that some of the insects will most likely escape, and they will soon give you a fresh brood; and therefore smoking with tobacco is the most

certain cure, as the smoke will get into every hole and cranny. Even that, however, must not be too strong, continued too long, or presented in a hot state, or the tobacco may do more harm than the insects. A glazed cloth covering to put over bushes is a good mode for smoking them, only the smoke must be cool. The green fly is easily killed, but we have noticed the viviparous progeny come from the dead bodies of their parents, and thus, independently of eggs, occasioning fresh necessity for the smoke and the wash. Nothing that has come in our way equals in this respect the brown and black insects of the *Aphis persicæ*, and the evil is that they get in wood, on walls, in pots, in the earth anywhere and everywhere; and when you have settled one generation, in a short time you have several more to try your patience and resignation. On a hot day recently we found a hard gravel walk swarming with them. Last night we smoked them, and on examining an infested shoot with a microscope could not discover one alive. We placed the shoot and leaves in a cup, covered it up securely, and find that out of some hundreds two or three have recovered so as to be just sickly; many others that last night were plump and fat-looking are now thin and shrivelled as well as dead; but lots of little brown things are sticking about, too large to have come from eggs, and showing every sign of having come from the dead bodies of their parents. Plenty of young, but not living, could be squeezed from the dead bodies of their parents; so we must just smoke again. These trees have had washings of almost everything, and with the fingers too; but if the wash was very strong the trees suffered, and if weak they only tended to lessen the evil; and even when the fingers were used, and they and the liquids killed where they touched, a very small point—even a quarter of an inch missed—would, from containing some scores, soon give you millions to kill and destroy. Smoking is, therefore, the most effectual remedy next to catching them and killing them. In most cases, whether by smoking or washing, one or two applications will generally be ineffectual, because, though strong enough to kill all which are alive, it will not kill those not then alive, or even the eggs that may be deposited. Our opinion is that there is but little production in summer by eggs, but that most new races are produced in a viviparous state; but information on this subject is necessary.

One word more. When the fingers are used to squeeze such insects—and an active boy will soon thus go over a Rose tree—care must be taken to wash off all such remains of the insects with syringe or engine, or the famed hydropulps, as such squeezed remains are as hurtful to the plants as a strong dose of tobacco or Gishurst. Dusting the insects with *nux vomica*, *hellebore*, snuff, &c., will soon settle those on which it lights; but the difficulty is that the quickest eye cannot see them all, and then there is just more room for those that are left to breed all the faster. Very few of such insects will stand 130° of hot water syringed on them; but then, whatever part is missed will give you occasion for another repetition, and growing plants will not stand that long without injury—in fact at this season 120° is high enough. Of course the water gets cool a little by being thrown on—a different affair from dipping. If dipped at once, even in 120°, few insects will live; but the branch must not remain above half a minute or a minute in the water. The natural history of some of those insects by one of our first-rate entomologists, such as those whose initials sometimes honour these pages, would be extremely interesting.

A little chloride of lime would remove the smell from liquid manures, as sewage, guano, &c., and should be given in proportion to the strength of such manure. Superphosphate of lime is one of the best manures for inside purposes, and when in small quantities on the surface soil, or mixed up with water, hardly retains any smell after the watering. For all out-door purposes the earth is the best deodoriser.—R. F.]

CYANOPHYLLUM MAGNIFICUM.—I give you the dimensions of a plant which I have of this. I bought it in June, 1862, with one pair of leaves about 6 inches in length, and the stem not more. The stem is now 3 feet high from the surface of the pot, and the following figures give the length and breadth of the last four pair of leaves respectively, beginning at lowest:—24½ inches by 11½, 27½ by 12½, 29½ by 13½, 27½ by 14½. This last pair have not yet attained their full growth. The plant is in most vigorous health, having received from the first moist stove treatment, a rich compost, and frequent waterings with weak liquid manure water.—A SUBSCRIBER.

THE PROPOSED GARDENERS' SOCIETY.

I HAVE from week to week anxiously conned your pages, fully expecting to meet with some short article from more than one, giving their opinion as well as their full concurrence in the proposed Society, the prospectus of which appeared in your columns a few weeks ago. I was loath to take up my pen to advocate its claims to the notice of the craft generally, for the simple reason that I know there are plenty of older and more able hands who could set the Society in motion if they would only put their shoulders to the wheel, which if once fairly started I think there need be no danger apprehended.

That some such society is required few will deny; and I am only more astonished to see it is not by this time in working order. You have as journalists done all that could reasonably be expected; but the apathy displayed by those for whose benefit it was intended, I fear shows that the scheme was only received with the "cold shoulder." Notwithstanding all this, I still trust the Society will go on and progress; and you may rest assured if once fairly started it would not suffer for want of members and sub-scribers to its funds.

It was only the other day I had the question put to me by a neighbouring gardener, "What society do you belong to?" My reply was, "Well, none at present. I am waiting to see what was to be the upshot of the proposed new Society." "Exactly the same with me; and farther than that, should the Society not go on I shall join another in connection with our profession." Through him I was induced to write thus briefly on the subject; and although the suggestion remains dormant I hope there is life in it, and that it will spring up into vigorous action. Is it not possible to secure at once two hundred members and start the Society? Remote as we are, and cut off to a considerable extent from the society of gardeners, I still fancy Ireland would furnish her quota of members.—A PRACTICAL GARDENER, *North of Ireland*.

[We can only remark upon the above that we are quite as much surprised as our correspondent by the apathy evinced by gardeners towards a society so calculated to secure for them comfort in sickness and old age; but the apathy is as manifest as it is lamentable.—EDS. J. or H.]

"PROCEEDINGS OF THE ROYAL HORTICULTURAL SOCIETY."

THE June Number of this Journal, and a list of the Society's Fellows, Committees, &c., are suggestive of a few commentaries.

It is satisfactory to find announcements in the Journal indicative of an attention to economy. The "Proceedings" are not to be published in August, September, October, and November—"that part of the year when most of the Fellows are abroad or out of town." This will be a saving, though a small one, and if it stood alone would be on a par with ceasing to purchase "Moore's Almanac," which a spendthrift announced as a beginning of economy; but the next item of retrenchment is larger—Mr. Weir, the Society's collector in Brazil, is recalled.

In addition to the above official announcements, there are rumours afloat that the expenditure on the Kensington and Chiswick Gardens is to be very largely reduced, but having no specific information we refrain from commentary further than to say that wages, forming a large item in the last balance sheet, other than those given to the Society's garden staff, might be reduced without decreasing the Society's efficiency.

THE MERITS AND DEFECTS OF ANNUALS.

I AM glad to see that you have lately drawn so much attention to annuals in your valuable Journal; I have given much time and trouble to them for several years. No other tribe of plants, in my opinion, combines such a brilliancy of colouring with a graceful and slender habit of growth. I fear I must add, no other plants require so much care and attention.

Annuals have so many enemies, and are liable to so many diseases unless they get exactly the treatment they like, that I have often been almost disheartened with the failure of many once-promising pets. I persevere, however, always trying by experiment to find out those which are at once hardy and beautiful, requiring no protection from slugs, and not liable to damp-off. I keep a list of such to which I am continually adding the

results of my experiments. This list is especially valuable to me in one way. Every spring I give the children of our national school, and also those cottagers who are in the habit of exhibiting flowers or vegetables at our horticultural show, packets of seeds of annuals, &c., and I find it is almost useless, except in a very few cases, giving such as the slugs are particularly fond of, or such as require very careful and delicate handling.

Every year I am deluged with catalogues of annuals from the different London houses in common with every one else who has the good fortune to possess a garden. I am often, indeed, astonished at the liberality, or generosity, or whatever it may be, of those firms who year after year present me by post with a book got up generally in a most elaborate way, with a great deal of literary and scientific skill, and to whom, notwithstanding, I have never given an order even for a threepenny packet of seeds. It may afford them some gratification, at least, in return for their liberality, to know that the perusal of their catalogues is a source of great enjoyment. The *Saturday Review* says that you may enjoy your continental tour twice over, first of all in turning over the leaves of your "Bradshaw," seeing therein all the places to which you might go, and finally choosing which you will visit, and secondly in the actual travelling. In the same way I, for one, thoroughly enjoy looking over the lists of annuals, "new," "good bedders," "showy," &c., which may be bought at prices varying from 3d. to 2s. 6d., even though I have resolved at the outset not to spend more than one guinea in the purchase of the same.

While on the subject of catalogues, I cannot help remarking that they are very far from being what they might be, and that describing almost every annual as an excellent "bedder," simply because "bedding" is the fashion, is more likely to do harm than good.

One catalogue gives a very useful list of "ineffective annuals." With regard to this character, there must, of course, be always two opinions. For instance: your correspondent, Mr. W. Earley, Digswell, places *Nolana prostrata* in a list of "twenty select annuals," while Messrs. E. G. Henderson & Son place it among annuals not worth growing. In this case I am myself inclined to side with Messrs. Henderson, while I would not with them exclude the golden showers of yellow Hawkweed.

But why should not the catalogues give us a little more practical information, marking, for instance, with an asterisk those annuals which open only in sunshine, and again distinguishing those to devour which a slug will walk or crawl a hundred yards even in dry weather; in fact, those plants which are to them what toasted cheese is to mice—a treat of peculiar flavour and delicacy, and scented from afar? If any one of your readers has been unfortunate enough (a long while ago, of course, but perhaps not quite forgotten yet), to put his *Portulacas* in a shady situation, or discovered a fine, fat, black slug eagerly devouring his French *Marigolds*, he will understand the value of such information as I have suggested.

As Mr. W. Earley, Digswell, says that he makes the attempt to select twenty annuals "rather in a spirit of inquiry," I would venture to criticise his list thus: Nos. 1, 2, 3, 4, 14 open in the sun only, and are, consequently, not, I think, generally useful, although there can be no two opinions with regard to the beauty of 1, 3, 14.

Again: Nos. 5, 6, 8, 9, 15, are fit for the greenhouse only, and are, therefore, subject to the same remark. No. 16 is too much like, and at the same time too inferior to, the *Verbena* to be a select annual. No. 10 is, as I have already said, unworthy of such a position, and, I think, in selecting twenty out of the great numbers of truly select annuals, there is no occasion for giving, as in Nos. 1, 2, 3, 4, 8, 9, two different species of the same genus.

Were I to give a list of annuals at once generally useful and select, confining myself to annuals strictly so called, it would be (omitting *Mignonette* and *Sweet Pea*, as universally acknowledged to be both) the following:—

- | | |
|---------------------------------|---------------------------------|
| 1. French Marigold * | 11. <i>Saponaria calabrica</i> |
| 2. <i>Clarkia</i> of kinds + | 12. Poppy of kinds |
| 3. <i>Collinsia bicolor</i> | 13. <i>Linum grandiflorum</i> ° |
| 4. <i>Lavatera</i> | 14. <i>Love-lies-bleeding</i> |
| 5. Ten-week Stocks | 15. <i>Lobelia gracilis</i> |
| 6. <i>Malope grandiflora</i> | 16. <i>Silene pendula</i> + |
| 7. <i>Perilla</i> | 17. Candytuft of kinds + |
| 8. <i>Convolvulus minor</i> °† | 18. <i>Eschscholtzia</i> + |
| 9. Virginian Stock + | 19. Sunflower of kinds |
| 10. <i>Nemophila insignis</i> * | 20. <i>Ipomæa</i> |

Those marked thus *, readily devoured by slugs; thus †, left altogether untouched by them; thus °, open in sunshine only.

Of the above, Nos. 5, 7, 9, 10, 11, 13, 15, 16, are alone of any use for bedding purposes. Nos. 4, 6, 14, 19, are especially beautiful in those glorious old borders of tall herbaceous plants which are still to be found in some gardens. Some may be astonished at my inserting No. 16, which so very much resembles common Robin-in-the-hedge, but if sown in autumn it makes in April and May what the children call a "pink pie"—that is, a perfect semi-ball of pink flowers, which can be seen half a mile off, and, as far as colour goes, quite equals the well-known *Saponaria*; the latter sown in spring will immediately succeed the *Silene*, with another pink pie.

I make these remarks in the same spirit of inquiry as Mr. W. Earley, Digswell, and shall be glad to see any further suggestions from correspondents of wider experience than—S. L. J., *Cornwall*.

P.S.—Mr. W. Earley, Digswell, may, perhaps, say that while striking out 5 from his list because of opening in the sun only, I have myself suggested two which do so. But the usefulness in other ways, and the great beauty of the scarlet *Linum*, and the minor *Convolvulus*, more than make up for this great deficiency.

ALYSSUM SAXATILE.

I AM glad your correspondent, "RUSTIC ROBIN," at page 414, has called attention to the merits of this fine spring-flowering plant. With regard to the variety called *compactum*, I might add that we have had it in general use for several years, and the past spring we had some hundreds of plants of it in flower. Hitherto we have simply called it *A. saxatile*, dwarf, not knowing it was dignified with a distinct name; it is of very compact habit, and the whole plant is covered with a half-globe of the closest-packed golden flowers, which also continue much longer than many other flowers of similar hue. With us it bears cutting-in and transplanting at any time of the year, and always yields its myriads of blossoms at the proper time.

For many years we were in the habit of propagating the *Alyssum* extensively for planting in the beds that are in summer devoted to bedding plants, the plant itself looking well all winter, and flowering early in spring. Occasionally beds of evergreens are edged with it, and nothing could look richer than some beds of newly-planted *Rhododendrons* that had an edging of the dwarf variety the past spring. I find it is most easily cultivated from seed, and the dwarf one comes true raised in that way; it also strikes very freely from cuttings, but of late years we have adopted the mode of saving a little seed and raising a stock. A variegated variety we are obliged to propagate from cuttings, and as a variegated plant it looks well, and flowers freely; it is less compact than our dwarf, but less lanky than the old *A. saxatile*. Of all spring-flowering plants none excel this for general utility in dry soils.

The *Hepaticas* are deservedly favourites, but somehow we cannot get them to do here; they will not endure moving twice a-year and flower well, as this *Alyssum* does. On the merits of other plants I shall at a future time more fully enter, but none are greater favourites with me than that spoken so well of by "RUSTIC ROBIN."—J. ROBSON.

THE TRAINING OF THE PELARGONIUM.

At the metropolitan exhibitions there are few things which excite more surprise among the uninitiated in gardening matters than the training of *Pelargoniums*, and, strange as it may appear, even some of those who might be considered *au fait* in such matters have not hesitated to confess their want of knowledge, for but a few years back, we heard the late Mr. M'Nab remark at Chiswick, "I think nothing of your *Heaths*, having better at home; but how those magnificent *Pelargoniums* are produced I cannot understand;" and, certainly, when we look at the small pots and vast mass of foliage and flowers, it does almost appear incredible that they could be so produced; and, great as may be the merit in growing a fine *Heath*, it is quite certain that more expense and attention are requisite to grow a comparatively fine specimen of *Pelargonium*. Those who have not tried the experiment will laugh at the idea of *Pelargoniums* requiring as much skill as *Heaths*; but we have grown both, and consequently can speak from experience; and we are quite sure more attention for the time is required to grow a perfect specimen of *Pelargonium* than to grow a specimen *Heath*; and it is rather remarkable that the man who may excel in the management of

one plant is rarely first-rate at the other. In fact, hardwooded and softwooded plants require treatment entirely distinct from each other; the first requires time and attention, the other little time, great attention, and rich manure, for it is only by much nutriment and careful management in watering, by seeing the plants receive sufficient, and yet are never glutted, that success in the management of softwooded plants can be rendered certain. If larger pots are allowed, less attention would be required, but merit would decrease in the same proportion, and consequently small pots are preferred. We all know that a *Heath* or any other hardwooded plant with its indurated foliage, and comparatively small respiratory powers or surface, cannot require so much aqueous support as a *Pelargonium*, but yet they are generally grown in larger pots, and consequently in larger masses of soil. How is this? Let those who have their management inquire, and we have no doubt the investigation will repay the trouble.

Various plans have been recommended for training the *Pelargoniums*, and doubtless the low bushes generally seen are not of the most elegant form that could be conceived, but possibly they are the most suitable, and hence necessity, our great preceptor, has compelled us to adopt that form. Anything, however, is better than the long-leggy formless things we used to see, and which in some places are seen even at the present day. The pyramidal form would certainly be the best, but nature rebels against it, and it is found impossible to get plants equally covered with bloom or of equal growth. It is well known that the sap of a plant in its progress rises always to the most vertical point, and that in consequence it is impossible to get equal growth over the whole surface of the plant; for pinch, top, depress, or do what you will, the flow will still be upwards, and the growth must be strongest at the most vertical points, and there will be bloom, while the lower branches will scarcely produce a flower. Even on the dwarf system of training it is found very difficult to insure an equal distribution of sap, as some shoots, especially those upon the most central and vertical branches, are always disposed to produce the strongest shoots, and it is only by occasionally removing them, or tying the points below the level of the weaker shoots, that an equal distribution of sap and growth can be insured: therefore, great watchfulness is necessary, and considerable practical knowledge to guide aright the energies of the plant.

It is sometimes remarked that *Pelargoniums* require neither training nor staking, indeed there are certain writers who would interdict the use of stakes altogether. Such writers, however, are more to be pitied than laughed at; they belong to a race of arm-chair gardeners, who find it more convenient to teach by precept than example, and whose lucubrations are more remarkable for detailing what they would do than what they have done. Such men are useful in their way, for even slovenly gardening is better than no gardening at all. But, once for all, we may say *Pelargoniums* cannot be grown to any size without supports; when in free growth a rough wind would blow them limb from limb; and as for carrying them to an exhibition without smashing them to pieces, it would be impossible. That less stakes than are generally used may suffice, and that they may be used of a much smaller size is quite true; but to attempt to carry a plant without staking is quite out of the question. Do not, however, use any more than are absolutely necessary, and let them be as thin and unobtrusive as possible. The best are the young shoots of the *Snowberry* (*Symphoria racemosa*), and the next small tough, dry, young *Willow* shoots. Either of these kinds will stand for a season, and when dry they are so tough and wiry that they may be bent in any direction, and will retain their form.

The annexed engravings show a set of young plants from the

Fig. 1.

Fig. 2.

first start in October in small pots, up to a fully-formed plant. Fig. 1 is a young plant just purchased from the nurseries, the

head of which has been taken off to form a cutting, and the buds of which are breaking into young shoots. Three shoots are produced, and those after growing to the length of 4 or 6 inches are stopped by pinching out the points, produce their lateral shoots and flower in the autumn; and after being thoroughly ripened by exposure to the full sun, are cut down as represented in fig. 2. This is what, in nursery parlance, is termed a young stool or bottom, and is the sort of plant which an amateur should select to grow into a nice specimen. In fig. 3 we have

Fig. 3.

the same plant grown another season and cut down; and here it will be seen it has added materially to its size, and has become a really fine ground-work for a specimen plant. But to form these bottoms is not quite so easy as to write about them. Young Pelargonium shoots are formed of brittle material, and hence considerable care and patience are necessary to get the shoots into the requisite form. We first begin with long hooked pegs, and peg the shoots into their places a little at a time, say depressing each shoot a little every three or four days until it gets into proper shape; always, if possible, taking advantage of the sunny part of the day, and allowing the plants to be rather dry at the time. In the afternoon of a sunny day, and before watering the plants, you may take much greater liberties with the young shoots of a Pelargonium than would be safe in the morning; and hence that time should always be chosen. When the plants get too large for pegs, small sticks of the necessary strength are used, placing them wherever it is necessary to draw the branches to, and to avoid using many stakes a band of bass, mat, or wire is passed round below the rim of the top and made fast; a piece of fine matting or string is then tied to the various branches, and each is drawn into the position it is destined to occupy. When the branches are depressed below the level of the rim of the pot, an arrangement of this kind is indispensable, and independently of that, it is a very neat way of accomplishing our aim. Without a properly formed stool it is impossible to get a perfect plant; and, therefore, no pains must be spared to arrange the branches properly before they get too much crowded with foliage. Sometimes branches are liable to split in the fork—that is, where they start from the parent stem, and then, before attempting to train them, the branches must be tied together by means of strong pieces of soft matting. Thus arranged, with perseverance and patience, the plants may be made to assume any form you please, but they must be gently handled; and hence, never attempt to train a plant except when you have leisure to do so carefully, and without hurry.

Fig. 4.

In fig. 4 we have the plant advanced another year, and it is

now of a size sufficiently large for all ordinary purposes. Such a stool, with proper management, and if of a free-growing kind, such as Queen Superb or Reine des Français, would form a plant from 4 to 6 feet in diameter, and should produce more than a thousand trusses of flowers—a sight worth seeing, and an ample recompense for the trouble that has been taken in its formation. Such stools are rarely to be bought; those who have them do not like to part from them. The stools represented in our engravings are not ideal sketches, but actual portraits of plants growing in our own establishment, which we shall be happy to show to any one who may call upon us. No. 2 is a young stool of Jenny Lind; 3, that delicate kind called Picturata; and 4, Queen Superb. Larger stools of the same kind may be found, but not more perfect than Nos. 3 and 4. Of such free-growing kinds as Queen Superb, it is possible, by sacrificing the flower, to grow a plant of the size in one season; but of Picturata, Formosa, or Fairy Queen, it would be good work to get them of the same size in three seasons. The reason is this, they only produce wood-buds at or near the base of the shoots, and hence we have no choice but to cut back to them; but the Queen-bred ones, as they are called, grow more vigorously, and hence may be cut much longer.—W. P. AYRES, "*The Fancy Pelargonium*."

LEAVES OF BEGONIA GRIFFITHII ROOTING.

ON the 4th of June, 1862, some of the leaves of Begonia Griffithii, along with numerous others of the same class of plants, were given to a lady in this vicinity. I was surprised to learn about three months ago that one leaf of Griffithii was still fresh as the day when it was taken off the plant, and had actually made roots in the glass of water wherein it was put at the time the others faded and died. But to have a full conviction of the fact I examined it on the 9th of this month, being one year and five days since I took it off the plant. Well, its silky-looking roots fold round the inside of the glass which contains nothing but pure rain water; and all up the stem, which of course is constantly immersed in water, there are a dozen or more young plants showing themselves, but none at the base of the leaf, where it is generally propagated from. Griffithii was in close succession after Rex was introduced. It is a well-known fact that Begonias like a moist close place; but becoming an aquatic is another matter.—ALPHA.

[The fine-leaved Begonias have, many of them, singular powers of vitality. We have found slips and pieces of leaves rooting on damp floors, where they had been accidentally dropped. They will do even with little water if the atmosphere is at all moist.]

TYING MATERIAL.

HAVING read Mr. Robson's article in No. 116 of your Journal I beg to inform him that I have received from Messrs. Dickson, Hogg, & Robertson, of No. 22, Mary Street, Dublin, three samples of different materials as substitutes for matting and Cuba bast. They are labelled, "Japanese Flax," "Green China Grass," and "White China Grass." The two latter are best; they are cheaper than bast, and much superior to it for both in-door and out-door work. They are first-rate for tying pot-plants, as they can be drawn to a hair-like fineness; they are much improved by being put in water for an hour before use.

I think when they become better known they will entirely supersede Cuba bast and matting for garden purposes.—G. G. Wells.

JOTTINGS FROM PARIS, 1863.

UNDER this head there is in page 432 of THE JOURNAL OF HORTICULTURE a sort of account rendered by "D." of Deal, of the vegetable part at the last horticultural show in Paris. Having been absent from home I only yesterday became acquainted with the article in question, the real motive of which I leave others to appreciate.

Had my Strawberries really been such as "D." of Deal finds particular pleasure in representing to the readers of THE JOURNAL OF HORTICULTURE, I am sure that not only the Judges would not have given them a first prize, but they would not even have been admitted by the parties charged with the arrangements of the Exhibition. If "D." of Deal did possess a little more

practical knowledge of gardening he would not have considered it strange that in France, on the 8th of May, some of the sorts composing my lot were not of the same size as those frequently shown in London by Mr. Smith and others. This is easily explained. Of course on the 8th of May no out-door Strawberries are ripe in this part of France, and consequently my lot consisted chiefly of what is called "afterfruits" of forced plants, the finest of which were then gathered. Thus it is quite natural that the berries generally could not be of enormous size. Had the Exhibition taken place a fortnight earlier, when my crop was at its best, the fruit would have been very near the size attained by the best growers round London early in June. This, I think, sufficiently proves that in France there is something better than the "Fraise des quatre saisons;" and that upon the whole it would have been wiser of "D." of Deal to abstain from his satirical report.

As to his observation of my having written "prodigious things" on Strawberries, I leave my fragarian friends in England to decide whether there was any exaggeration in what I humbly submitted to the public. Whatever I wrote was done in the most impartial spirit, and never exceeded the truth.—FERDINAND GLOEDE, *Les Sablons, Moret-sur-Loing, France.*

SUCCESSION OF FLOWERING HERBACEOUS PLANTS.

I SEE in the gardening world those who, like myself, are not so passionately fond of so much bedding stuff. Why should we? Are there not many hardy herbaceous plants equally beautiful that would require but little care? Like our bedding plants, the more care taken of them the better they would become.

We have great men who take economy for their motto. Would it not be more economical if they were to turn their attention to those plants that are much hardier? We now have to find pits, frames, covering, besides a great deal of labour and some firing, to protect them. Surely that is not economy.

I have talked to some about this matter. They say "We should not have the great variety of colour which we have in the bedding stuff." No, neither do we want it. Where is the need of a number of shades? In my opinion we only want distinct colours, and we have these in the hardy plants.

I think if our nurserymen and cross-breeders were to spend half of the time and money on the hardy class that they do on the most tender things, we should soon have them much better than they already are. Or have they been so much improved that there is no more room for improvement?

Why I thus plead the cause of hardy plants is this. I am writing in the middle of June when bedding plants have scarcely made a move, and before they get properly into bloom it will be at least mid-July; or, supposing we count from now, there will be June, July, August, and then comes September, when we may expect frost to cut them off. So we have to nurse them from eight to nine months, and we have only three months of pleasure from them. That would not be the case with the more hardy plants. There are many that bloom early and late. I will give a list; every one wishing to have bloom all the year round might select from them and their varieties:—

JANUARY.—*Eranthis hyemalis*, *Helleborus niger*.

FEBRUARY.—*Arabis alba*, *Bulbocodium vernum*, *Cyclamen coum*, *Helleborus foetidus*, *Hepatica triloba*, *Scilla sibirica*.

MARCH.—*Anemone apennina*, *Anemone nemorosa*, *Arabis alpina*, *Aubrietia deltoidea*, *Aubrietia purpurea*, *Cyclamen europæum*, *Erythronium dens-canis*, *Gagea glauca*, *Helleborus atro-rubens*, *Leucojum vernum*, *Narcissus Tazetta*, *Scilla amœna*.

APRIL.—*Alyssum saxatile*, *Arabis rosea*, *Atragene canadensis*, *Doronicum caucasicum*, *Erythronium grandiflorum*, *Fritillaria imperialis*, *F. præcox*, *Gentiana acaulis*, *Iris pumila*, *Leucojum æstivum*, *Libertia grandiflora*, *Narcissus jonquilla*, *Omphalodes verna*, *Ornithogalum umbellatum*.

MAY.—*Achillea ptarmica*, *Achillea tomentosa*, *Ajuga alpina*, *Ajuga genevensis*, *Ajuga reptans alba*, *Armeria dianthoides*, *Armeria maritima alba*, *Asperula odorata*, *Bellevallia operculata*, *Corydalis sibirica*, *Czakia liliastrium*, *Dielytra spectabilis*, *Dodecatheon integrifolium*, *Hesperis matronalis*, *Hoteia* (*Spiræa*) *barbata*, *Iris cristata*, *Iris sub-biflora*, *Lupinus macrophyllus*, *Lupinus polyphyllus*, *Ornithogalum montanum*.

JUNE.—*Adenophora verticillata*, *Allium Moly*, *Asphodelus luteus*, *Camassia esculenta*, *Cerastium tomentosum*, *Gladiolus*

byzantinus, *Iris amœna*, *Iris florentina*, *Iris sambucina*, *Iris-lirion montanum*, *Lilium bulbiferum*, *Mimulus variegatus*.

JULY.—*Acanthus spinosissimus*, *Aconitum variegatum*, *Asclepias syriaca*, *Asclepias tuberosa*, *Epilobium spicatum*, *Epilobium spicatum albiflorum*, *Liatris squarrosa*, *Lilium tigrinum*, *Lychnis chalcidonica*, *Mimulus cardinalis*.

AUGUST.—*Aconitum japonicum*, *Chelone obliqua*, *Coreopsis grandiflora*, *Funkia subcordata*, *Liatris spicata*, *Solidago humilis*.

SEPTEMBER.—*Acis autumnalis*, *Allium azureum*, *Amaryllis belladonna*, *Anemone japonica*, *Bulbocodium versicolor*, *Colchicum byzantinum*, *Colchicum variegatum*, *Liatris elegans*, *Oporanthus luteus*, *Solidago canadensis*, *Tritoma pumilis*.

NOVEMBER.—*Aconitum autumnale*, and many more might be added. I have given the time of these coming into bloom; some of them will last two or three months.

In giving the above list let it be understood it is not intended to exclude the bedding plants altogether—far from it. They will make a good addition to herbaceous plants. I hope some of our more experienced men will give their opinion on the subject.

P.S.—I forgot to put in the proper place the following well-known favourites, which might be added to the above list:—*Asters*, *Phloxes*, *Dianthus*, *Larkspurs*, *Foxgloves*, *Snapdragons*, *Hyacinths*, *Tulips*, *Daisies*, *Polyanthuses*, *Pansies*, *Violets*, *Forget-me-not*, *Hollyhocks*, *Pentstemons*, *Campanulas*, *Crocus*, *London Pride*, &c.—G. H.

HOT WATER VERSUS FLUES.

I THINK that the gardening world is much indebted to Mr. Robson for bringing this subject so prominently forward. I am perfectly satisfied that the more it is ventilated the more good will be derived from it. I, like Mr. Robson, am situated in a dear coal country, with coal at 19s., and steam coke at 21s. per ton without cartage, which adds 2s. 6d. per ton to the cost. I cannot advocate the cause of flues against hot water from experience, having had the working of flues and hot water in the same place, for the vineries followed in succession, thereby depriving me of the data which are necessary to arrive at a correct estimate. I always felt certain that, making allowance for the difference in temperature, a third less fuel was consumed by the vinery heated with hot water.

I perfectly agree with Mr. Robson, that the best boiler is not yet obtained. I have a No. 5 tubular boiler from an eminent firm in London, that when we are in the full tide of forcing, consumes more than two tons of coke a-week. Some time ago, out of curiosity, I placed a thermometer in the top of the chimney, about 16 feet high, in eight minutes it indicated 260°. How high it would have read I do not know, as the thermometer split to pieces the instant I replaced it.

I feel convinced I could work a small vinery of 25 feet by 12, with the waste heat of this boiler. Such is the opinion I have formed from four years' experience of its working here. As far as my experience goes, I am inclined to think that boilers are not so much at fault as the contractors for the heating apparatus.

If more piping were allowed—say a third more than what is now considered to be sufficient, the apparatus after becoming heated would not require so great a combustion to keep up the desired heat. A more steady and moist heat would thus be obtained, and if a third less fuel could be saved, which I think might be the case in those counties where coal is so dear, the balance will do far more than outweigh the first cost of piping.—W. MC. L.

MILLIPEDES—CLUB ROOT—GARDEN MICE.

How could I destroy the insect which I have enclosed? It is most destructive to my Strawberries. I have gathered quantities of these with holes eaten quite through, and have found the insects curled up in the middle of the berry. With me I think they are more destructive than the slugs.

Is it the same insect that causes the Cabbage and Broccoli to club? I cannot plant anything of the kind that has to stand in the ground long, without a large ball being formed at the root to the size of a half-pint cup, and I find from two up to twenty or more of these insects when I take up the roots.

I am also very much troubled with what is called the grass mouse. This mouse has destroyed nine Melons, the largest one

at the time being the size of a good Apple. Four of them were nibbled in two or three places, and the leaves and runners I could take out of the frame by handfuls, till one light was literally cleared of the foliage altogether. I tried to trap them, but could not catch one, and to poison them, but they would not eat the bread that I put the poison on.

If any of the readers of your Journal could instruct me as to the best way to get rid of these pests, I should receive the information with thankfulness.—A CONSTANT READER.

[The specimen sent is the snake millipede. We have seldom found them so destructive. The centipede is more fond than the millipede of getting into fruit and coiling itself up, as in Apples, Peaches, &c. You can do little now with your Strawberries, unless in the way of prevention. We have tried beanstalks cut into six-inch lengths, and dipped in a weak solution of sugar and water. They will at times lodge in these, and you must dislodge them as you would do an earwig. A dressing of lime and soot would help to keep them also from the Strawberries, as they do not like travelling over such materials. The eggs are deposited in holes in early summer, and are soon hatched with the heat. Lime and soot are very disagreeable to them. This is all we can say. Would some friends be kind enough to help in this, and also the following cases?

The Cabbages are clubbed by quite a different animal—a small weevil; and the chief cures for it are examining the plants before planting, removing all the small clubs or knots, if any, and killing the small grub weevil; then dip the roots in a thick paste mortar formed of soot, lime, and soil, three parts of the latter to one of each of the former, before planting, and use soot in the first watering afterwards. If a little soot and lime are put on the ground after the plants begin to grow all the better. This weevil seems to shun all nitrogenous matter and ammonia. It will also be good policy to change the Cabbage ground every year. If so looked over at planting time, and the ground is freshly and well dug, and well manured, and if soot and lime are used in watering, there will be little of the club in old or young plantations. In places where the weevil has become very numerous, it is a good plan to let the plants grow to a fair size, and to well examine them before final planting.

We can sympathise with you as to the grass mouse. He is not easily trapped, and is also difficult to poison. We have poisoned him by throwing with a brush, not with the hand, a little arsenic into the pieces of Melon or Cucumber he had been tasting. Generally, traps baited with bread, or poisoned wheat, &c., are useless, he will not look at such hard materials; but we have caught him in figure-four traps, by placing some tempting green delicacy below the overhanging heavy tile, and nibbling about it brought it down. If he lodges in a hole of the bed, he can also be brought out thence as a half-drowned mouse, by pouring painful after painful of water in the hole, and, having previously removed the glass from the frame, there is little difficulty in pouncing upon him. The most certain way, however, is to notice his runs, and place in his route either small steel traps, less than for rats, or hair traps, made of a stout hair, with a running noose, exactly on the same principle as the poacher adopts for rabbits, hares, and pheasants. We have used all these means with fair success, when we have been troubled with such visitors. It is useless, in general, to present such a mouse with anything tempting, unless it be green. We once had a pit of *Calceolarias* levelled with the ground. The frost was intense outside, and they had not been uncovered for three weeks. The worst of it was, the mouse had eaten but little, and he seemed to have hit upon cutting over for diversion. Most of the roots broke again though weak, and the cut tops made good cuttings, if not too much nibbled.]

ENTOMOLOGICAL SOCIETY'S MEETING.

THE June Meeting of the Entomological Society was rendered a special one, the members having been especially summoned for the purpose of taking into consideration the following report of the Library and Cabinet Committee, dated the 30th March last:—"That the present income and the financial prospects of the Society do not warrant this Committee in believing that the Society is or will be able to provide the sums requisite for forming a collection of British insects which shall be worthy of the Society, and for maintaining the same in a satisfactory state. This Committee, therefore, recommends to the Council that the Society's collection be discontinued, and that proper steps be

taken for the disposal of the specimens and cabinets. The Committee, however, further recommends, that the type specimens be not dispersed but placed in some public institution where they will be readily accessible and available for scientific purposes, and the Committee suggests the feasibility of some arrangement by which the specimens in question might be placed in the British Museum."

At its first foundation the Society's chief objects were—1, the formation of an entomological collection; 2, the formation of an entomological library; 3, the publication of the Society's "Transactions." The valuable collection of the late Mr. Kirby was presented entire to the Society by its venerable possessor, and large additions were made by the late Messrs. Children, Hope, and many other members. It was, nevertheless, found after the experience of many years, that a small society like that of the London Entomological Society was only encumbered by the possession of a collection which required the attention of a Curator, involving considerable expense. In addition to which it was found that the collection did not keep pace with the progress of the science, whilst the expense it entailed on the Society crippled the more serviceable objects of an entomological library, and especially the publication of the Society's "Transactions." Several years ago, accordingly, it was proposed by some of the members that the entire collection should be disposed of (as had been done by the Entomological Society of France, and has since been done by the Zoological Society of London, and is also proposed at the present time to be done by the Linnean Society), but the proposition was only partially adopted by the sale of the exotic portion of the collection. Circumstances have since, however, shown that it would be advisable to carry the proposition fully out, especially as the original constitution of the Society contemplated the study of exotic as well as British entomology, and the objections against retaining any part of the collection were equally strong against the British as against the exotic portion of the collection. Under these circumstances, and with the examples of so many other Societies before them, it is not surprising that the proposition of the Library and Cabinet Committee was adopted by the Society at large, and we have since had the pleasure to learn that the type specimens, including, of course, Mr. Kirby's collection of British Bees and other insects, rendered valuable from having served as the type of the descriptions published by other entomologists, have been transferred to the British Museum, where they will have a much surer chance of being preserved and made available for the use of students than they would have had if they had remained in the possession of the Entomological Society.

At the general Meeting of the Society held on the same evening, the President in the chair, Mr. Stainton exhibited some small Lepidopterous larvæ which had been found mining in the leaves of the Hazel. The same larvæ having been also found on *Kibes sanguineum* and in Birch leaves. They were supposed to be those of *Incurvaria pectinea*.

Mr. G. R. Waterhouse exhibited specimens of an apparently new British species of *Homalota* (a genus of minute Staphylinidæ).

Mr. F. Bond exhibited hermaphrodite specimens of the Orange-tip and Swallow-tail Butterflies; in both of which the right side of the individual exhibited the female, and the left side the male form, contrary to the usually observed state of such specimens.

The President also exhibited drawings of two hermaphrodite specimens of the Honey Bee, the different parts of the body exhibiting sexual differences of the male and worker Bees; also, specimens of *Braula cœca*, a small wingless parasite infesting the hives of the Honey Bee, which had been imported into this country with the Ligurian Honey Bee, in a hive of which variety these parasites had been found.

Mr. McLachlan read descriptions of three new British species of Caddice Flies (*Trichoptera*), of which he exhibited specimens.

Mr. Stainton read some notes on a curious Lepidopterous insect, *Tinea vivipara* (Scott), described in the "Transactions of the Entomological Society of New South Wales," as being viviparous in its habits; also, notes on the "Proceedings of the Entomological Society of Philadelphia."

The Secretary also read a letter from Mr. C. A. Wilson, of Adelaide, giving an account of the entomological captures of Mr. F. G. Waterhouse, the naturalist attached to the South Australian Exploring Expedition under Stuart, which had recently succeeded in crossing the Australian continent from Adelaide to the north-west coast and back again.

SOME PLANTS AND GARDENING OF AFFGHANISTAN.

The dwarf Palm, which mainly composes the "jungal," or brushwood, in this district, and is called in the vernacular "Maizarri," or "Mzarrai" (Tiger-grass), is applied to a great variety of useful purposes by the natives. From the entire leaf are made fans; from the leaves cut into strips are plaited mats; from the fibres of the leaf and its stalk, which are first prepared by maceration in water and bruising, so as to separate them from the parenchyma, ropes are made; and from the finer fibres are made the sandals commonly worn in the country, and termed "chapli." The chapli is usually worn by all the hill tribes of Afghans, instead of the ordinary shoe, and though not so durable perhaps, is much better adapted for walking over rocky ground. The downy hair found in the axil of the sheathing leaf-stalk of the dwarf Palm is used as tinder, and is sometimes soaked in the sap of the Mulberry tree to make it more inflammable. The delicate white embryo leaves in the centre of the leaf-bud have a sweet and astringent taste, and are in great repute, and of common use, as a domestic remedy in cases of diarrhoea and dysentery. These same leaves, however, when they become more developed, lose their sweet taste and become very sour, and are still astringent. In this state they are used as a purgative medicine, but chiefly, however, for horses and cattle.

The Logar district produces corn in great abundance, and, together with Ghazni, is one of the principal granaries of Kabul. It also produces great quantities of Apricots and Grapes, both of which are extensively exported to Hindustan. The Vines in this district are cultivated in the same manner as in Turkey, and differently from the method usually adopted in other parts of the country. Here, instead of being grown in deep trenches, and their branches supported on the intervening ridges of earth, or on frameworks of wood, the Vines are planted in regular rows, and trained like bushes by pruning and clipping their branches and tendrils. The Grapes are chiefly of the varieties known in the country by the names of "Hussaini" and "Shaikh-khali." They are gathered before they are quite ripe, and packed in "drums" of poplar wood between layers of cotton wool, and in this state exported to Hindustan. So great is the trade in these fruits that the Poplar tree is regularly cultivated in copses for the supply of the material for these "drums." The trees grow to a great height, and very straight, and no branches are allowed to grow except near the summit. About the eighth or ninth year the trees are fit to cut down. The wood is very white and soft, and from want of durability is never used for building purposes when other timber is procurable.

Besides these fruits, all the vegetables commonly met with in England, except the Potato, are largely cultivated; and among others a kind of Leek, called by the natives "Gandanna." The leaves of this plant are used as a vegetable in these parts, in the same way as Spinach is with us. The plant is perennial, and cultivated in a peculiar way. The roots are never dug up, but the leaves are cut away two or three times in the year, a new crop succeeding in due course of time after each cutting. In the spring and autumn the surface earth is carefully turned, mixed with a top-dressing of manure, and freely irrigated. Some of these Gandanna-beds continue to yield for an astonishing number of years. In Logar we were credibly informed that several fields of this vegetable were twenty-five and thirty years old, and that in Kabul there is still flourishing a field of Gandanna which was sown in the time of Nadir Shah, upwards of a century ago. Clover and Lucerne are extensively grown in Logar as fodder. The crops, after being cut and dried, are rolled into thick cables, and thus stored for winter use.

During our march through this district our camp was daily supplied with quantities of Rhubarb, of which our troops and camp-followers consumed several bullockloads, both raw and cooked. Rhubarb is a very favourite article of food amongst the Afghans, by whom it is eaten both in the fresh and preserved state. In the former case it is as often eaten raw as cooked, but in the latter it is only added as a relish to other dishes, meat or vegetable. The plant is never cultivated, but grows wild on the neighbouring hills and in the stony soil at their base; and in these localities it is collected by the neighbouring villagers, who bring it into the populous districts for sale. We met with the plant in two forms. In the one the leafstalk was greenish-red externally, coarse and stringy within, and altogether extremely acid and disagreeably bitter. In this state the Rhubarb is called "chukri"

by the natives, and it is simply the natural condition of the plant. The other form was quite different from this. The stalk was white and smooth, very juicy, and of a pleasant subacid taste. This is called "rawash," and is the blanched leafstalk of the wild plant. This condition is produced artificially by the villagers, who, in the spring, when the leaves are just commencing to sprout, cover them over with a heap of loose stones and gravel, so as to shut out the access of light. This "rawash," when cooked, has a delicate flavour, and is much superior to the Rhubarb commonly met with in England.

The Vine is very extensively cultivated in the suburban gardens of Kandahar, and they produce no less than nineteen different kinds of Grapes. In two or three of the largest vineyards there are wine-presses, but the quantity of liquor produced is very limited, as its use is entirely confined to the chiefs and wealthy classes, who can indulge in the forbidden drink with less fear of obloquy or punishment than the poor people, who are more amenable to the discipline exercised by the priesthood. The wine made at Kandahar is red, and is prepared from Grapes of the same colour, which are known to the natives by the terms of "Rocha-i-Surkh," "Sahibi Surkh," "Lal i Sufaid," "Lal i Surkh," &c. The Hindu population consume large quantities of a fiery spirit distilled from dried Grapes, called "Kishmish i Sufaid," and "Kishmish i Surkh;" and they are helped in this by many of the Mussulman inhabitants of the city, who, however, do so secretly. The Khatin Grapes produce the well-known Manakka Raisins, met with in India. The Sahibi Surkh and Sahibi Ablak produce the sun-dried raisins, called, from the fact of their being void of pips, "Kishmish i bedana." These raisins are very small, of a light green colour, and very sweet taste. They are largely exported, and also consumed at home in immense quantities. The "Rocha i Surkh" and "Rocha i Sufaid," as also "Toran," are Grapes of an inferior kind, and are mostly consumed in the fresh state by the poor. The "Hassaini" and "Shaikh Khali" Grapes are of great size, of a pale green colour, and very delicate flavour. They are gathered before they have quite ripened; and, packed in drums of poplar wood between layers of cotton wool, are exported to Hindustan in vast quantities, and even find their way down to Calcutta. The "Acta" Grape is also of large size, but its flavour is inferior. It produces, however, excellent raisins, called "Kishmish i daghi," or "abjosh," which very much resemble the best kinds of the bloom-raisin met with in the English market. They are prepared by dipping the fresh and ripe bunches for a moment or two into a boiling solution of quicklime and potash, previous to drying in the shade. Besides the Grapes noticed, there are other varieties, which are either altogether consumed in the fresh state, or else are converted into raisins by drying in the sun. And in this form they are largely exported to Hindustan.

Besides Grapes, the gardens around Kandahar produce many other kinds of fruit, such as the Apricot, Plum, Peach, Cherry, Apple, Pear, Quince, &c.

Of the Apricot (Zard-ālu) eleven varieties are to be found in the Kandahar district. The "Kaisi," "Charmaghz," and "Charbaghi" varieties are those most esteemed. They are largely consumed in the fresh state, and are also preserved for exportation to Hindustan by drying in the sun. But previous to this process the fruit is sliced open, its stone removed and split, the kernel extracted, and then replaced in the fleshy part of the fruit. In this form the Apricot is called "Khubāni." The variety named "Pas-ras" is, as its name implies, the last to ripen. There are two kinds, a large and small. These, together with other varieties, named "Surkhcha," "Sufaidcha," "Plan," "Shams," and "Shakarpara," though generally consumed in the fresh state, are also dried; but the stone (or putamen) is not removed: in this state they are called "Taifi." To the taste they are very acid, being generally dried before quite ripe: they are chiefly used as a relish to many Afghan dishes, and as a component of some kinds of sharbat. Gold and silver-smiths use a hot decoction of these fruits for the purpose of cleaning and giving a bright lustre to their metals.

Of the Peach (Shaft-ālu) there are only two kinds at Kandahar. The one called "Babri" is an inferior fruit, of small size and acerb flavour; but that known as "Tirmah" is a very splendid fruit, of great size and luscious flavour, and much superior to any I have ever met with elsewhere.

Of the Quince (Bihi) there are three kinds—viz., the "Shakar," or sweet Quince, the "Tursh," or sour Quince, and the "Mians," or Quince of medium quality. The first kind is generally consumed fresh, and is also often carried about the person on ac-

count of its agreeable perfume. The other kinds are generally candied, made into jams, or cut into slices and dried for future use as an adjunct to other dishes. The seeds of each kind are demulcent, and are added to sharbats. Both the fruit and the seed are exported.

Of the Pomegranate (*Anar*) there are six or seven varieties. Those grown at Panjwai are the finest, and most highly esteemed; they are of great size; the pips are of blood-red colour, very juicy, of excellent flavour, and perfectly sweet, without any of the tartness belonging to other kinds of this fruit. The Panjwai Pomegranates are justly celebrated throughout the country, and large quantities are carried from this to the Kabul market. The fruit-rind of all the varieties is an article of export, as well as of home consumption, for the use of tanners and dyers. The root bark is a common domestic remedy for diarrhoea, and is also used as a vermifuge.

Of the Fig (*Anzir* or *Anjir*), which mostly grows wild, there are two varieties: one bears a black fruit called "Makkai;" the other a white, called "Sada." The fruit of both kinds are small and sweet. The former are strung on thin cords and exported; the latter are consumed at home.

Of the Mulberry (*Tut*), which also grows wild, there are nine or ten different varieties. Some of them are preserved in the dried state, and eaten with Almonds and raisins, or with Walnuts and parched Maize or Lentils. In the northern parts of Afghanistan the Mulberry tree is very abundant, and the people of these districts use its fruit as a substitute for corn flour. The bread made from the flour of dried Mulberries is said to be sweet, wholesome, and fattening.

The abundance and consequent cheapness of all sorts of fruits in this country is quite astonishing. The natives indulge in them often to excess, always most freely, and suffer in consequence, especially the poor, who, for several weeks of the summer season, know no other food.

Before taking our leave for the night, Fattah Mohammad Khan arranged a shooting party for the early morning, to beat over the corn fields around the city walls, which were now swarming with quail, and proposed that on the conclusion of the sport we should join his breakfast party in the garden of the Sardar Rahmdil Khan, where he promised we should have an illustration of the Afghan style of feeding.

The invitations for both were accepted, and accordingly daylight found our party, gun in hand, on the quail ground, where shortly afterwards we were joined by Fattah Mohammad and his suite. Our dispositions were soon arranged, and by sunrise we commenced beating the fields outside the Kabul gate of the city. Gradually working our way round the southern walls, we at length struck off towards Rahmdil Khan's garden, where we arrived at about ten o'clock. Here we found a large assemblage of guests awaiting our arrival in a tastefully decorated "baradarri," or summer-house, the upper balconies of which overlooked a piece of ornamental water that seemed to extend nearly the whole length of the garden, and terminate below another baradarri at the other end. We had hardly commenced examining the fairland scene before us when our attention was drawn off to the noisy activity of a small army of cooks, who were busy under an adjoining clump of Mulberry trees preparing the various dishes that were soon to regale us, and the savoury odours from which vied with those from the flower-stocked parterres that in one continuous strip of fringe bordered on either side of the tank already referred to, whilst both combined to perfume the air with most grateful and appetising effect on the olfactory—warning of the good things that were coming.

Whilst breakfast was being prepared, we seated ourselves on divans in an open balcony that overlooked the greater extent of the garden, and faced another but smaller summer-house near its opposite end. The garden itself is a walled enclosure of, perhaps, six or eight acres in extent, and of an oblong shape. Near the centre of the distant sides stand the two summer-houses. Each is a tastefully-devised but gaudily-painted building, consisting of two stories; the lower is occupied by stabling and servants' houses, whilst the upper contains a principal central room that opens on to the balcony, on each side of which are the projecting windows of the side rooms; the walls of these rooms are decorated with flowers, arabesque patterns of mosaic, and figures, principally, however, of dancing girls and boys.

Along the centre of the garden, and extending from one summer-house to the other, is a shallow masonry reservoir full

of water; it is so arranged that at intervals of 50 or 60 yards or more, the reservoir rises in a step of 4 or 5 feet, producing a small cascade by the falling of the water from the one to the other below it. On the sides of these reservoirs are series of fountains, the perforated tubes of which indicated the variety of elegant patterns in which they were arranged. Beyond the fountains and the border of the reservoirs the ground was laid out in one long continuous strip of flower-beds on either side, which at this time were in full bloom, and from the variety of their bouquets and hues imparted to the scene a most charming appearance and delightful fragrance. The fountain-tubes were, unfortunately, greatly out of repair from long neglect, "or," as Fattah Mohammad said, "he would have made them play, for their not working was the only thing that detracted from the resemblance of this garden to 'Bihisht,' or 'Paradise.'" On either side, and beyond the flower-beds, were straight gravelled paths, some 4 feet or more wide. Each extended the whole length of the garden from one summer-house to the other, and, like the reservoirs, &c., rose in terraces, by a few steps at a time, at intervals of 50 or 60 yards. These walks were flanked on the outer side by single rows of stately Cypress and white Poplar trees, which formed a boundary wall, as it were, to the ornamental portion of the garden, for the rest of the space beyond them was laid out in vineyards, orchards, and corn fields. The orchards were composed mostly of the Apricot tree; but there were also the Plum, Cherry, Quince, Mulberry, Fig, and other fruit trees. Notwithstanding the delights of this garden in its fresh and fragrant youth of spring, there was great room for improvement in that portion of it allotted to the pleasure and ornamental grounds. On this part the artist's labour was certainly very deficient, for there was a painful absence of variety or taste in the disposition and arrangements of the different terraces.

Looking from the balcony of the large summer-house to the one at the opposite end of the garden, the intermediate space was occupied by a series of rigid straight lines. In the centre lay a narrow and long sheet of water, which stretched away in low terraces to the other end of the garden, where it seemed to end in a point under the opposite summer-house. On either side of this was a band of variegated flower-beds, then a plain path, and finally a single row of tall slim Poplar and Cypress trees that ranged after each other in alternate succession. Beyond these the space was one confused mass of foliage. The little cascades in the centre of the prospect, produced by the water falling from one terrace to the next below it, were the only exceptions to the otherwise stiff and monotonous appearance of the garden.—(*Bellew's Mission to Afghanistan.*)

WORK FOR THE WEEK.

KITCHEN GARDEN.

HOE in dry weather between all crops in rows if they are not mulched with grass or short dung, to kill weeds and to loosen the soil around the plants. We strongly recommend the mulchings between the rows of vegetables, for wherever the ground is at all stiff and exposed at this season to the powerful action of the sun, it is apt to crack and rend in several directions, by which the roots of vegetables are in many instances destroyed. *Beans*, a few Mazagans may yet be put in, which will produce late in the season, if the weather proves favourable. *Broccoli*, Cape and Grange's Cauliflowers may now be planted where the early Peas have been gathered. If the weather continue dry they will require an abundant supply of water. *Cabbage*, sow a little more seed immediately, if the sowing recommended last month has failed. *Chervil*, another sowing to be made for succession. *Dwarf Kidney Beans*, the last principal sowing to be made. Earth-up the advancing crops. Those in flower would be benefited by a good soaking of water. *Endive*, continue to plant out a few once a fortnight to keep up a succession. Another sowing to be made. *Leeks*, those sown in drills to be thinned to a foot apart in rich ground. The thinnings will do to plant out. *Parsley*, a sowing to be made so as to get strong plants by the winter. *Peas*, earth-up and stick the advancing crops; water those that are in bearing. A few more may be sown, which will come into bearing if the autumn is favourable. *Radishes*, make a sowing of the various sorts. The Turnip-rooted are generally preferred at this season. *Vegetable Marrow*, these plants will require a liberal supply of water during the continuance of dry weather. Stop the main shoots to cause

them to throw out laterals. In all cases of earthing-up crops in dry weather, give them a good soaking with water previously.

FLOWER GARDEN.

The Roses should now receive particular attention, the standards to be well staked, the shoots disbudded and stopped, and the roots mulched or supplied with liquid manure as they may require. Budding to be commenced on all stocks from which the bark will rise freely, and such as are more sluggish in their circulation to be excited by a copious supply of liquid manure. Do not be afraid of thinning the free-blooming sorts of a Perpetual character. The old Bourbon Queen and the Crimson Perpetual, for instance, will produce twice as many blooms as they can permanently maintain. By a judicious and constant attention in this way, fine blooms will be insured until the frost sets in. Take up Tulip-bulbs whenever the weather will permit. We do not imagine that the late excessive rain has been of any service to them. When lifted do not separate the offsets from the parent bulb, or remove the roots or skin. These had better remain to a later period. Tie carefully the spindling shoots of Carnations and Picotees, not too tightly. Lay Pinks and Cloves for potting. Russian Violets may be separated and fresh plantations made. Remove all decayed flowers and seed-vessels from American shrubs. This will not only give them a neat appearance, but will in a great degree add to their strength, and as a result of this, an abundant bloom next season will be secured. Now is a fine time for layering Rhododendrons, Belgian Azaleas, &c., just as they are coming into full growth. Push Dahlias on by watering freely when the weather is dry; also, assist them by mulching the ground with decayed stable-manure. Take care that the plants do not chafe where attached to the blooming-sticks. The present is a favourable time for putting in cuttings of all the most showy herbaceous plants, selecting for the purpose the small shoots not furnished with bloom. A north border is a suitable place to strike them, and a hand-glass will facilitate their rooting. Pansies for autumn-blooming may be treated in the same way. Attend to the staking such of the herbaceous plants as require it before they get blown about and injured by high winds that sometimes occur about this time, and do not huddle the stems together as is too frequently done. Give plants infested with green fly a liberal washing with the engine, or syringe them with tobacco water. Mildew sometimes becomes troublesome after this season; it may, however, be kept in check by applying sulphur to the parts affected the moment it makes its appearance, first wetting them with water in order that the sulphur may stick.

FRUIT GARDEN.

Proceed with nailing-in the young wood of wall trees, and see that they are perfectly clear of insects; also stop any gross shoot, and endeavour to secure a fair supply of bearing wood all over the tree. Gross shoots that were stopped early in the season should be divested of all the laterals if not wanted to fill up vacant spaces. Strawberry-runners to be procured for new plantations. Those who cannot spare ground for a new plantation may prick them out in prepared beds about 6 inches apart, and remove them with balls in October. Also complete as quickly as possible the layering of runners for forcing next season, bearing in mind that one week now is worth two at the end of the month, and that strong well-matured plants are only to be obtained by early layering and good after-culture, and that no amount of care next spring will compensate for late, and, consequently, badly-rooted plants.

GREENHOUSE AND CONSERVATORY.

Should these plant-structures require repairs or cleaning, the stock may be removed with greater safety at this than at any other period; it is injudicious to leave the completion of such work until late in the season. This is generally a critical month with greenhouse plants out of doors. The fervid heat is sometimes so great as to produce the tropical winter of vegetation when the parching heat of the sun acts upon and produces in some degree a dormancy in the system of plants, and at other times when showers fall and we see the surface of the soil in the pots moist, we are satisfied until the drooping or withering foliage upbraid us for our neglect, and, perhaps, with Heath, New Holland, and other such plants it is noticed when too late to save. These ill effects may be avoided by plunging the pots in coal ashes, and by syringing the plants overhead of an evening, and examining them when doubtful on the subject by gently turning one or two out of their pots to see the state of

the ball, as it requires some experience to distinguish whether a plant wants water or not from the ring produced by rapping the knuckles against the side of the pot. W. KEANE.

DOINGS OF THE LAST WEEK.

MUCH the routine of previous weeks, such as staking Peas, hoeing ground, pricking-out as well as planting-out Celery, Broccoli, Cauliflower, &c., earthing-up slightly Potatoes to prevent the tubers being greened, cleaning Mushroom-bed, spawning fresh piece, regulating Cucumbers, and giving manure water to Capsicums, Tomatoes, &c.

FRUIT GARDEN.

Went over trees as much as we could get at them; thinning and fastening-in Apricot and Peach shoots; ditto Pears against walls; thinning shoots and picking the points off from dwarf standard Apple, Pear, and Plum trees; washed and engined Cherries and Plums against walls, using rather strong clear soot water; put the litter closer up to rows of Strawberries, and netted them from birds. Crops pretty fair, single specimens not so magnificent as usual. Those in front of an orchard-house are still rather the best for flavour. Have never seen, however, Black Prince finer out of doors, and what is better, many housekeepers are thanking Mr. Cuttill it has proved such a firm good preserving Strawberry, and though darker in colour, yet superior, on the whole, to the old scarlets generally so used. Keens' Seedling used to be very much in vogue for preserving, but it is much inferior to the Prince, being much more soft and juicy. Some late kinds, as Elton and Eleanor, preserve well, if not too much ripened. These do well whole in Currant juice. Find that from strewing the ground slightly with soot and lime, there is little probability of trouble from slugs or other crawlers. Planted-out forced plants as room could be found, as such plants turned out last year are by far the finest and most fruitful now. Was obliged to smoke the Peach-house, though the fruit is ripe and ripening, and we would have avoided it if possible, as the fruit will last us for some weeks yet. We, therefore, pulled all that were ripe, that they might not be tainted with the laurel and tobacco smoke; we found we could not keep the Aphis persicae, that horrid brown and black insect, in check without it, as some of the fruit was getting discoloured from their excrement. Had to do the same with the orchard-house, after being pretty well beaten with the dusting and washing process. The orchard-house was kept in smoke from two to three hours, but the smoke was chiefly from burning laurel leaves that had previously been well bruised. Smoke from tobacco alone for that period would have been dangerous. Last night we could not find an insect alive, but to-day a few have revived, and lots of small ones have appeared, so that we shall smoke again to-night. Some that were put into a close vessel, seemingly dead, appear so this morning, with the exception of a very few very sickly, but there also appear a number of small dots of young ones that were not there the night before, no doubt viviparous productions. We never had this aphid before last year, and thought we had got rid of it in the autumn; but if spared another winter we will look after it even more sharply. All other insects we have met with are trifles to it. The hot weather, and being busy elsewhere, enabled it to reproduce itself quickly, and its powers of increase are almost fabulous.

In the Peach-house we syringed well where we could do so without displacing the fruit, as the few aphids left alive were very sickly; and as that syringing would bring them to the floor, strewed the floor with lime and soot, and watered slightly all over with hot water from a rose. Watered Fig trees heavily, as we knew we could not make the water stagnant. Late ones in orchard-house are showing well, and were also watered. If a Fig in a pot gets at all dry when it has very young fruit, they will drop to a certainty. This is one reason why, without this care Figs in pots are more uncertain than those planted out. With this precaution, comparative dryness to ripen the wood in autumn, and more dryness and freedom from severe frosts in winter, water gradually given until all the ball is moistened in spring by the time the fruit shows, and regular moisture at the roots afterwards, without stagnant water, no tree does better in a pot than the Fig. Without these cares it will be better planted out, and stubby shoots secured by confining the roots, and pinching the shoots. Went over the trees in orchard-house; and as respects Peaches, Nectarines, Plums, &c., gave them pretty well their final thinning of fruit, as most of them are set,

and altogether have set some ten or twenty more fruit than could be left. We fear we have pretty well overdone the Cherries with crops, yet the trees do not show it. We must try and get some more plants another year. We hear that such kinds as we have been growing in an open house, and gathering for three weeks, and which in ordinary seasons would not be ripe for nearly a month out of doors, are considered better flavoured than when grown out of doors—such as Bigarreau, Napoleon, Belle Magnifique, Reine Hortense, or even Empress Eugénie, to say nothing of May Dukes now over, unless a few late ones. These have scarcely been touched by an insect, though the beetle was so troublesome on the Peaches. It is right to state, however, that some of the trees of the Peaches were in rather an unhealthy state before they were covered with glass.

Gathered Melons from frames before they were too ripe, and potted-off others for succession, as we have kept the soil so dry that there is no great chance of the old plants breaking strongly. In planting afresh, will put in small drain-tiles upright, that we may moisten the soil beneath without wetting the top as the fruit approaches maturity. Placed the fruit thickly set in a brick pit on saucers. They had previously been elevated in pots, but we like the fruit to be shaded by the foliage instead of exposed. Proceeded with cutting-out bunches of Grapes, and thinning those left in a late vinery as we could get at them, as the bunches will have to hang through most of the winter.

ORNAMENTAL DEPARTMENT.

Proceeded with potting, &c., as detailed in previous weeks. *Ranunculuses* ripening should be taken up. Tied herbaceous plants; prepared for doing so with Hollyhocks. Hoed the beds on lawn, and tied and pegged where necessary. Mowed and machined the grass on lawn; find that Green's single-man machine of 16 inches is liked better than a two-man machine of 22 inches. One of our neighbours works a twenty-two-inch one with one man; but I should not like to be the man. The lesser machines are so beautifully hung that one man uses the sixteen-inch one with less toil than two men do the twenty-two of most makers. We find that the objections we made a year or two ago about the chains do not apply to the nice steel chains now sent out. We are glad to say that our men prefer them by far, and as being easier work than the scythe. At the same time people who send men to cut long grass, and the ground is all up and down and unlevel, need not be surprised if the machine is thrust into a corner, and the men cannot and will not use it. We must, however, pass this and a great many other matters over to say a few words on

SHADING.

Owing to the extreme heat and force of the sun, we shaded the upright front of our conservatory by painting the glass with jelly size made hot to boiling, putting in a quart of jelly, a half quartern of turpentine, and the same of boiled oil, and about the size of a walnut of pounded whiting. This is put on pretty hot and very thinly on the glass when dry, and then a dry brush daubs it, and it looks neat like ground-glass, and will keep on until the dark days of autumn. Some pits needing a dense shade had the same material put on with a whiting-brush, and no nice daubing given afterwards. For a slight shading in an extra hot day, we find nothing better than just colouring some water with whiting and throwing it on the glass with a syringe; and thus the glass may be pretty well covered, or just slightly spotted to blunt the force of the rays. Some people object to all such simple modes, and equally object to blinds and rollers outside; but would like a neat permanent shade for their greenhouses inside, so as to be independent of rains, winds, &c. Well, the best we know for this purpose is bleached calico or linen, or white canvass made into pieces to suit one or two lights. On such pieces place small rings top and bottom, and every 18 or 24 inches along the sides, and place these rings on hooks at similar distances in the rafters and sash-bars. Such nice blinds may remain up from the month of April to October, and even then it would be easy to unhook them if required in dull weather. If the material is thin and white, this unhooking will seldom be necessary during the summer, and the method has much of neatness and even of economy in comparison with outside blinds to recommend it. Of course, such blinds might also be made to roll; but that would increase the intricacy and the expense, and for particular places we would prefer these removable blinds.—R. F.

TO CORRESPONDENTS.

We cannot reply privately to any communication unless under very special circumstances.

WORMS IN STRAWBERRIES (Tyro).—The "worms" are Snake Millipedes (Julus). We know of no mode of preventing them eating the fruit. They breed in the soil, and the only effectual remedy would be to pare and burn 6 inches depth of the entire surface soil.

WORKS ON GARDENING (A Young Beginner).—"The Orchid Manual," 2s. 6d., "The Fern Manual," 5s., and "In-door Gardening," 1s. 6d., are all published at our office, and can be had free by post if sixpence additional is sent. They contain all the information you mention.

SEEDLING VERENAS (H. Barham).—They were totally shrivelled.

INSECT ON CUCUMBER LEAF (C. P., St. Margaret's).—It is a small crab-spider (Chelifer cancrioides), which, doubtless was among the red spiders on the Cucumber leaves for the purpose of devouring them.

IMPROVING A LIGHT SOIL (A. L., Birmingham).—Clay, chalk, marl, and bricklayers' limy rubbish are the only additions to your light soil that will permanently improve its staple, and thus enable it to retain moisture better in summer. In the absence of those improvers cocoa-nut fibre dust, half-decayed tanners' bark, and the vegetable mould you mention, would be good additions. If you cannot permanently improve the staple of the soil the best compensation is mulching the surface. If this were done between the rows of crops and over the roots of trees with spent tanners' bark, or, still better, cocoa-nut fibre dust 2 inches deep, we believe that with liberal manuring any hardy plant may be well grown on a light soil.

GUANO WATER (A Cottage Gardener).—Half an ounce to a gallon of water is strong enough for potted plants, and one ounce to the gallon for plants in the beds.

CAMELLIA SOIL (Idem).—Turfy loam and sandy peat in equal quantities form the best soil for Camellias. What is written in "Work for the Week," and "Doings of the Last," except as to the stove and greenhouse departments, are as applicable to the cottage as to the mansion, and we are always prompt to answer queries. Amateurs should have our "Garden Manual," and our "In-door Gardening," and "Out-door Gardening." In them will be found all the usual routines of culture for common plants; and with these and answers to queries in our correspondent columns no one need find gardening difficulties frequent and never insuperable.

MOWING MACHINE (Civis).—Any one of the machines will do its work well. We cannot recommend any maker.

APPLE BLOSSOM (John Shaw).—The Apple blossom is a fine semi-double flower, which we suspect is not permanent. Has it come so before? If it has, graft the shoot which produces them on an Apple stock, and you may be able to secure this new form.

MANAGEMENT OF ANEMONES-BRED (W. B.).—If the foliage of the Anemones be quite yellow, take them up at once. When left in the ground the matured root is prone to start into growth. Choose a fine day to take them up, dry them in the sun, and keep them in a dry cool place until October, when they may be planted in the bed again. After the Anemones are taken up add a little fresh soil to your bed, fork it in, and you may then plant any kind of bedding plant in the bed, as Geraniums, Verbenas, &c. If you do not like the trouble of taking up the Anemones every year, and have not the convenience to keep bedding plants, we would advise sowing some of the showiest annuals between the Anemones the last week in May, scattering a little fine mould over them. Any of the following make good beds:—*Blues*.—*Nemophila insignis*, *Nolana atriplicifolia*, and *Convolvulus minor*. *Reds*.—*Centranthus macrophyon*, *Saponaria calabrica*, and *Candytuft*. *Yellows*.—*Venidium calendulaceum*, *Erysimum Peroffskianum*, and *Bartonia aurea*. *Whites*.—*White Candytuft*, *Sweet Alyssum*, and *Nemophila insignis alba* and *maculata*. The best plan, however, would be to take the Anemones up and plant Stocks, Asters, French Marigolds, or anything of that kind immediately.

SEEDLING PEACH (Alice).—After waiting so long, it would be a pity to destroy the Peach tree now; but you might insert a number of buds in it near the base of the shoots. It may be worth nothing when you get it; but to prove what the fruit would be, we would thin the wood of the tree liberally, so as to give sun and air to the shoots left, and thus induce the ripening process. Then, in the middle of September, we would either root-prune, or replant this tree, and keep the tree shaded from sun until the leaves would stand without flinching. This would also encourage ripening of the wood, and lessen mere growth the next season.

CROSS-BRED GERANIUM (Christine).—We discovered only a small leaf, of which we can say nothing; but, from the description, we should have doubts as to its being a cross with Geranium. We can, therefore, as yet say nothing as to the hopes entertained.

CROSS-BRED VERENAS (Idem).—As to the crossed Verbenas, we expect something of the kind took place that our valued coadjutor, Mr. Beaton, demonstrated as respects Verbenas. Perhaps, however, your dwarfs might be made to grow. If not, like the piny Geraniums, they will be more interesting than useful. Such facts, however, are most valuable for enabling us to form correct theories. Your deductions from this and general facts are quite correct; but the more care in hybridising, the better may the results be expected to be. We earnestly hope that our friend Mr. Beaton will be able soon to enlighten us on all such matters.

GRUBS ON VINE LEAVES (X. F. Z.).—It is useless sending a leaf with insects wrapped up in an open letter. They ought to be securely enclosed in a box, or, at least, covered up securely with oiled paper. There were no insects on the leaf, but marks as if thrips had been there; but then we are doubtful if it was thrips from your saying that they eat into the leaves and the berries; for, though the thrips will soon suck the juice out of leaves and render berries very unsightly, it is seldom they make holes that can be easily seen. Your best remedy is to persevere with the smoking, unless you would go over the lower side of the leaves with a sponge and water, when you would most likely catch them.

HOLES IN VINE LEAVES (A Subscriber, Kilmarnock).—We think the leaves are injured by a caterpillar or some kind of weevil. Watch the place with a lantern at night, wrap the stem round with wool and oil, and that may keep them off.

ERROR.—At page 416, last line of first column, for "5 inches" read "5 bars."

EXHIBITING STRAWBERRIES (Ellen).—At the Royal Horticultural Society's Kensington Exhibitions the Society provides dishes; but the exhibitor, or the exhibitor's deputy, must attend to arrange the fruit.

SEEDLING PANSIES (Taffy).—We do not think that the flowers sent are equal to many of the same character which are now in cultivation. The Geranium was so fallen to pieces that we could make nothing of it.

BLACK DEPOSIT ON PELARGONIUM LEAVES (Elizabeth).—The black appearance is chiefly the excrement of insects, as green fly and thrips, particularly the former. The leaves had better be removed. We discovered no live insects. The warty appearance on the back of the leaf is almost a sure sign of stagnant water and insufficient drainage, or a too low close atmosphere. Good root-action and a dryish airy atmosphere are the best antidotes for this, and also for securing a healthy vegetation and freedom from insects. If the plants are in bloom and green fly on them, you had better remove them by the fingers, as smoking is apt to injure the blooms. If not in bloom smoke, but do it judiciously—not too much tobacco, nor yet allow the smoke to be hot.

VINE-BORDER COVERING—TREBBIANO GRAPE (B. J. J.).—You do not furnish us with enough of evidence to decide whether the gangrening of the berries has anything to do with the condition of the outside border. If, as you say, that the Vines are healthy and the roots near the surface, then we should be inclined to think that the fault was to be found in management, overcropping, &c. However, there can be no question that covering the border with glass will tend to the well-being of the Vines, as the light will get to the soil and cold rains be excluded. We have never yet done so ourselves, but we can see what an advantage such a covering would be; but that advantage will chiefly depend on the ground of the border being exposed beneath the glass in summer. If at such a time you cover the border with plants, either in pots or otherwise, then we have no great faith in the advantages you will attain. We know one case where Vines were much injured by such a glass covering, but the border had its top in a sloppy state all the summer from watering plants upon it, and the dense foliage kept the sun's rays from reaching it. The Trebbiano Grape is a strong-growing kind producing large white bunches, which, if well ripened in autumn, will hang all the winter with ordinary care, and the flavour is rich and sweet. Some people are very fond of it. It is chiefly useful in a late house.

CUCUMBERS DEFORMED AND YELLOW (A Perplexed One).—We fear you are expecting too much fruit from your Cucumbers. Though some varieties show three or four fruits at a joint seldom more than one swells, or should they all swell they are short crooked things, but more frequently they turn yellow at the point, as in your case. This is owing to the roots being unable to supply nourishment to the young fruit in sufficient quantity to keep them swelling freely. One cucumber at a joint, and that in every foot of space, is enough. Cucumbers seldom turn yellow at the point in the early stages of their growth, or not until a good many have been cut, which we attribute to a little over-greediness on the part of the cultivator. Although we consider too heavy cropping the chief cause of Cucumbers failing, yet anything like a check to the roots will bring about quite as unsatisfactory results. Too little bottom heat, too much or too little watering, or watering with water considerably lower in temperature than the heat of the bed causes an inactive state of the roots, and that will cause the young Cucumbers to die-off at the point. Syringing the plants with cold water, and allowing water to drip off the ends of the young fruit, and the sun striking them in that state, scalds them. Allowing a current of cold air to suddenly reduce the temperature will throw the sap back and hinder the fruit from swelling. Should none of the above account for the failure, water with weak liquid manure twice a-week, warmed to the temperature of the bed; for, if the fruit forwarded be a fair specimen, your Cucumbers lack nourishment. Keep the house moist by sprinkling every available surface twice a-day with tepid water. Give air early in the morning, and shut up early, never allowing the thermometer to fall much before you shut up. From 75° to 85° is quite hot enough for bottom heat in any stage.

GLASS (W. X. W., Bingley).—The sample enclosed by you would do very well for pit-glazing.

NAMES OF MOSSES (J. E. Dangstein).—1, Hypnum splendens; 2, Hypnum tritetratum; 3, Dicranum undulatum.

NAMES OF PLANTS (E. S., Hampton Court).—One of the Hippeastris, but not recognisable (if, indeed, it be not one of many wholly unrecognisable seedlings) after being squeezed flat. (*J. K. Rossiter*).—Cannot tell a plant from a mere leaf like that. (*James McBey*).—It is what is called *Echites picta* in gardens. We do not know *E. rutilans*. Camellias sometimes go spotted like yours; it is a sign of deficient vigour. (*W. B.*).—Looks like *Erigeron philadelphicus*. (*Omega*).—1, *Lotus corniculatus*; 2, *Orchis pyramidalis*; 3, bad, some crucifer without leaves; 4, *Matricaria chamomilla*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

EGGS SAT UPON AND THEN CHILLED.

I SHALL feel obliged by any of your correspondents giving me their opinion, from experience, as to the time when eggs being under a hen and then left would be bad. I put fifteen Sebright eggs under a hen at ten o'clock at night. She appeared to sit close. In the morning at six o'clock she was off the nest and the eggs quite cold. At eight o'clock the same morning they were put under another hen, and every egg proved addled. Would the six or seven hours be sufficient time to cause this? How soon does vitality commence, so as to spoil eggs if afterwards left to get cold?—**Evesham.**

[The fact that at six o'clock the eggs were quite cold, and that they were not put under another hen until eight, would account for their being addled. The hen should always be tried for three days on common eggs to see that she is really broody. Upon the question how long eggs may be sat upon and yet not

be spoiled if chilled, we should like to hear the results of the experience of our readers; and shall be obliged by such results being communicated, stating at the same time the variety of fowl by which they were laid.]

A FACT FOR NATURALISTS.

To-day I have an opportunity of reading of two cured specimens of the "Pintailed Sandgrouse" (*Pterocles setarius*), being in the possession of Mr. Wm. Emmett, of Pudsey, having been "murdered" by him only last Wednesday, at a neighbouring village called Farsley, and, so far as I can see, if all "naturalists" are of Mr. Emmett's stamp, both these and all other rare animals will continue to be very scarce, both on the undulating hills of Farsley and all other parts of these dominions. No doubt, now that Mr. Emmett's exploits have been duly chronicled, other naturalists (and members of the sparrow-shooting societies) will be on the look-out for the fortunate twelve out of the fourteen which so far have escaped the range of Mr. Emmett's rifle; and it seems very probable that the whole covey of fourteen will be utterly destroyed or driven to more barbarous climes to seek that existence which they are denied in this civilised land of ours.

It seems a great pity—nay, I may say, it is a national misfortune—that so many of my countrymen should exhibit such selfish propensities (I cannot use a milder term), in destroying those rare specimens of the feathered tribes which occasionally visit these shores, in order that they may have the gratification of exhibiting in their private collections stuffed and inanimate specimens of what but for them would be living types of the species to which they belong, and be a means of instruction and a source of pleasure to thousands.

I have not the slightest knowledge of Mr. Emmett. No doubt he is an enthusiastic if not a distinguished naturalist, and I give him credit for the best intentions; but I put it to him, whether he is not contracting rather than expanding a knowledge of nature by such acts? If the "Sandgrouse" are common on the arid plains of Persia, and found in plenty on the coasts of the Mediterranean, we have no occasion to shoot the few which visit us in order to procure specimens for our instruction.

Thanks to Mr. Emmett for preserving for us the plumage of the "Pintailed Sandgrouse" stuffed with "shoddy," with intelligence beaming from a pair of glass eyes; but no thanks to him for depriving us of the pleasure of seeing our native woods and valleys adorned with living specimens of these persecuted beauties, and debarred the pleasure alike of studying their habits, and admiring the splendour of their living forms.—**PRO BONO PUBLICO.**—(*Leeds Mercury*.)

[Heartily do we coincide in this condemnation.—**EDS. J. OF H.**]

PROLIFIC DUCKS.—I can add my testimony to your correspondent's relative to Ducks laying soon after having hatched a brood. One of my Ducks brought out a brood on Monday, May 4th, and on the following Sunday had laid three eggs. Even while sitting she did not avoid the drake. My other Duck was then sitting, and brought out her brood on the 2nd instant, and yesterday laid her first egg. The Duck that hatched her eggs on the 4th of May had on Friday last, the 12th of June, twenty-one eggs in her nest, and is now sitting on seventeen or more. She began to sit on Sunday last. A shopkeeper in this village informs me that one of his Ducks laid several eggs under the coop, and he has already (June 23), had two broods from the same Duck this year.—**K. O. T.**

LARGE EGGS OF SPANISH FOWLS.—The Rev. C. A. Moore, of Sutterton Vicarage, Spalding, bought some Spanish poultry about two and a half years since of Mr. Fowler, of Aylesbury. He says, "I have been very particular in keeping up the breed, and have had some very remarkable eggs from my stock. One egg which a hen produced about a fortnight since weighed 3½ ozs.; but the most remarkable one is that which the same fowl laid on Saturday, and which actually weighs nearly 4½ ozs. This egg I have had painted white in order to preserve it. My fowls have every disadvantage—being confined to within a very small space."

EXPULSION OF YOUNG BEES.

I HAD on the 1st of May a very strong hive of bees, a swarm of 1862. I cut a hole through the top of the hive (an old conical one) about the above date, and put on a super about the last week in May, when it was immediately filled, and the bees began to work. On the 1st of June it was abandoned, and the hive threw an immense swarm the next day. On the 13th the hive threw a second swarm, of which I cannot tell the weight; but there were about three quarts of bees. Two days after this I saw quantities of young bees unable to fly, ejected from the hive; and these were carried out again directly if returned. Two days later (the 17th) the hives threw a third swarm nearly or quite as strong as the last. And to day (the 18th) I again see scores of young bees under the hive—evidently ejected. There were also three young queens which were dead. The other bees were all alive and crawling about. I returned some dozens, but they were directly seized, carried out, and dropped on the ground. I am certain that many hundreds have thus been destroyed and cannot account for it, as food is very plentiful, and the hive though much weakened by throwing three swarms, has plenty of bees in it, and a very large number of drones. Indeed, I was almost led to fancy the destruction of young bees was because the drones took more food than the workers could provide; but there may be some other cause, and I shall be most glad to learn it.

The following incident occurred here a few days since. A swarm left a hive belonging to a bee-owner, and fortunately was seen to go off. They flew direct to a deserted hive full of old comb, standing in a cottage garden nearly half a mile off, where they entered and remained. The owner saw them go in and recovered them, making some compensation for the hive, in which I saw them to-day working beautifully.—ROBERT LEVETT.

[Although we never met with a similar instance, we should be disposed to attribute this wholesale expulsion of the rising generation to unfavourable weather setting in immediately after swarming had taken place, and thus calling into play that remarkable instinct which leads bees in extremity to sacrifice the weaker members of the community. Liberal feeding would probably have put a stop to this massacre of the juveniles. Nothing is more common than a swarm taking possession of a deserted hive.]

TRANSPOSING STOCKS—A QUEENLESS SWARM—DRIVING.

I HAD, on the second Wednesday in June, a second swarm, which I hived into a box about one-third full of comb and honey; in fact, all the upper part, the lower having been cut away because of its age. Having read of some of your correspondents transposing hives in order to strengthen weak stocks, I thought I would do the same with this, and therefore in the middle of the first fine day, the fifth after being hived, I changed places, the swarm with a strong old stock. The result was much fighting for two days and the weakening of the old stock as though a prime swarm had left it, without a very perceptible strengthening of the swarm. I now fear the swarm has no queen, because no pollen is carried in; nevertheless, as they are quiet, I infer they have some brood from which to raise a sovereign, but comb-building does not go on.

Now, were I to feed copiously, would the bees, having no fertile queen at liberty, build drone-comb only, permanently injuring the stock, a common square box with close top? And would it not be better to wait till pollen is carried, and then feed? What precautions are necessary in transposing hives to strengthen weak ones? What precautions are necessary in artificial swarming in consequence of the tendency of bees to build drone-comb while raising a queen, honey being abundant? How are the impressed wax plates fixed in frames, and is it desirable to employ them when perfect combs cannot be had? In the Woodbury straw hive are the bands of straw horizontal or perpendicular, and is it fitted with a straw cover?

There is one thing more. I made two unsuccessful attempts at driving to form an artificial swarm. The stock was a square box packed full of bees; the time I selected 5 A.M. The stock was carefully turned up and another box the same size put on, the box with comb afterwards tenanted by the second swarm above referred to. After drumming about ten minutes and thinking about half the bees had gone up, from the view I had through the box windows, I lifted the upper one off and put it in what

was to have been its place on the board of the old stock, treating the old stock according to the Bee-book. I congratulated myself on having cleverly accomplished my object; but in about an hour it was evident I had failed. I was, therefore, obliged to restore the hives as before. Nothing daunted, I tried again next morning and drummed longer, taking about half an hour in the process. Again I thought I had succeeded, though the bees were more savage; but again time showed it was another failure. I tried no more. It does seem to me there is some mystery in driving. I thought I was very careful, gentle, and precise in adhering to the directions. I am half inclined to suppose the stock had no queen at liberty, being engaged in rearing one, which would account for the failure; but I have had no experience in driving, and do not like to be beaten. The stock was populous, but has been at a standstill for a month, although rich in sealed honey. Does driving usually succeed, if continued long enough, in getting all the bees out? Are there some things to be carefully avoided in driving?—A. B. C.

[Transposing stocks succeeds best in the middle of a fine day, when honey is very plentiful. This is the grand secret of success. Every bee returning full of honey is usually a welcome visitor to any hive, and in this case little or no fighting results; but when honey is scarce and strange bees return with empty pouches, they are ignominiously expelled as a race of paupers attempting to saddle themselves on the resources of the community. No such transfer, however, should be attempted with a second swarm until it is certain that the young queen has commenced egg-laying. In your case the natural result has evidently followed. The queen, on her return from one of her excursions, has gone to the old spot and has been put to death by the strangers. As no brood can now exist in the hive, the colony must speedily dwindle away unless it is supplied with brood-comb, or, better still, a couple of royal cells; or, best of all, a fertile queen. If you wish the latter, and cannot obtain it on the spot, write to T. Woodbury, Esq., Mount Radford, Exeter. Bees without a queen build drone-comb only. Do not, therefore, feed copiously until this all-important deficiency has been supplied. Artificial should generally imitate natural swarming in this respect, that the swarm has the old queen and consequently builds worker-comb, whilst the queenless bees remain in the old hive, which is already filled with comb. Artificial partition-walls are easily fixed in frames by means of melted wax. The vendors will give you full instructions on this point. They are a great assistance when natural combs are unattainable. In the Woodbury straw hive the bands are horizontal. It is usually fitted with a wooden cover. We can add nothing to the usual instructions for driving bees. You should operate in the middle of a fine day, and persevere until you succeed. When once you have accomplished it all difficulties will vanish—at least, it was so in our case.]

LOSS OF A SWARM—DISTANCE BETWEEN BARS—ABNORMAL BEES.

HAVING procured a stock of bees last February, and being light, I fed them well through the spring till May 23rd, when they swarmed, weighing but 2½ lbs. Hearing piping two days before, I concluded the prime swarm had escaped unobserved. I wish to know if it is as my books tell me, that piping is never heard till after the first swarm. There has been no appearance of another. Am I to expect more from it?

I have used bar-hives 1½ inch from centre to centre, but found them too wide. What is the proper breadth, as bar-frame-hives are useless if each bar does not exactly contain a comb on its centre?

I here is on some of my bees the unusual appearance (at least to my eye), of an extra pair of antennæ of a yellow colour, growing from the insertion of the real antennæ. Have any of your numerous apiarian correspondents noticed it, and what may the cause be?—BEE FRIEND.

[Piping is so rarely heard prior to the issue of a first swarm, that you may be tolerably certain that yours has escaped unobserved, nor can you expect that another will now issue. Our bars are about a sixteenth under 1½ inch from centre to centre; but we consider the latter a very good distance. Singularly enough the proceedings of the bees themselves do not always afford the best guide as to distance, as they are so much in-

fluenced by the requirements of the moment. If honey be very plentiful they are apt to build thicker combs (almost to the exclusion of brood), than when honey is scarce, and the queen lays an egg in every cell as soon as it is braced out. We should be glad if you would forward in a small box by post a few living specimens of bees possessing an extra pair of antennæ.]

BEES DYING IN JUNE.

LAST year I had not a single swarm out of four hives. This year I have not had any yet, but expect three daily out of the three hives I have living. Last week a stock died, and I do not know the cause. They came out of the hive, and died on the board. When I saw this I took up the hive and saw but a very few bees left in, and they seemed quite stupified, and they all dropped on the board dead. I took out two combs, and found very few of the cells with young bees in them, these had grubs in them, but they were dead. The hive in May seemed quite well, and worked hard. What was the cause of death?

Last year I had a stock which died in March, with plenty of honey in store, but they were in a Nutt's hive. The bees were well and strong in February, and in March they died, and when I came to look at them the combs were quite mouldy. I thought that I must have taken the hive from under cover (I have a wooden shed) too soon, as it was very wet and cold in March last year.—W. W. C.

[The first-mentioned stock died of starvation—pretty strong evidence that the honey season in Lancashire is a bad one. The second was probably destroyed by that pest of wooden hives, internal moisture. Feeding would, of course, have been the obvious remedy in the one case, whilst ventilation might have palliated the evil in the other.]

VARIATIONS IN COLOUR OF THE COMMON HIVE BEE.

HAVING a wish to improve the circumstances of a poor neighbour in the country, I empowered him to purchase a hive and stock of bees, for which he (or rather I) paid 14s., that is 2s. for the straw hive, and 12s. for the bees. On going to see them a few days afterwards, I was surprised to find them so unlike my notions of bees—so slim, so small, so colourless, they answered to the French word of *mouches à miel*, but not of *abielles*. The man, however, declared he was used to this sort, and that they were making honey very fast. The situation lies between two parks, where, although there will soon be many lime trees in bloom, there are not many other flowers. Some mignonette and some borage have been sown, and I am told that buckwheat is a great favourite. I do not find these particulars mentioned in THE JOURNAL OF HORTICULTURE; and certainly the description of bees, whether Ligurian or British, by no means seems to correspond with these. Can they be wild ones?—A. A. Y.

[*Apis mellifica* is the only species of hive bee, whether wild or domestic, indigenous to Great Britain; and to this species the bees in question undoubtedly belong. They sometimes vary slightly in colour; and Mr. Lowe, of Edinburgh once possessed a variety of a lighter tint than usual, but these appear to be mere accidental variations. The Ligurian bee (*Apis Ligustica*) which has lately been so successfully introduced into this country, differs so notably from the ordinary bee, that it is ranked as a distinct species.]

SIMULTANEOUS ATTACKS ON DRONES.

On the only fine day of this week (or month), I received an expected first swarm from A, Woodbury bar-hive, two hours afterwards whilst looking on I observed a great and general issue of drones from A, B and C, and B and C having swarmed once and twice respectively, the workers appeared to attack the drones, riding on them curled up as they attack robbers. Being severely stung, I did not observe much more, but was surprised. First, Why should drones be turned out of a hive directly after the first swarm issues? Secondly, Why should the drones issue, if A, B and C be simultaneous, or were they all merely at play? I observe a few but not many dead drones about, and can still see them in A through the glass.

I have an old straw hive that was nearly burnt out by the accidental firing of my Vine-border when covered with litter. The bees issued for a moment on the 17th of June, but returned. They have clustered out largely for some weeks, and so continue. I purpose taking it when the proper time arrives? To-day I have added a glass-frame bar-super covered, to induce them all to enter and make comb. Is that right? I should like, on the issue of this swarm to join it (by sprinkling) to Wednesday's A swarm in a new complete frame-hive bought from Messrs. Neighbour. Will this answer with a housed swarm that has done nothing? I have fed them.—T. P.

[If the young queens in B and C were impregnated, the attack upon the drones is all in due course, and will probably be persevered in until all are expelled; but with A the case is different, the assault seeming to be a mistake, which when found out was at once discontinued. Owing to the bad honey season after the issue of the swarm, the bees found themselves with a sparse worker population, and scanty stores, which there was no immediate prospect of replenishing. These are just the circumstances which lead to the destruction of drones, which would, doubtless, have been consummated had not the virgin condition of the queen necessitated a reprieve. That all three stocks should inaugurate a simultaneous attack was a remarkable instance of like causes producing similar effects. Adding a super may be of use, if the weather improves; at any rate it will do no harm. The probability is, that the two swarms will unite peaceably.]

BEES NOT ENTERING A SUPER.

I HIVED a swarm of bees on the 17th of May, and in less than a month the hive appeared by its weight to be filled. For more than a week the bees have clustered out round the mouth of the hive, and small particles of comb are scattered about it also. There does not appear any diminution in the activity of the bees. In order to prevent a maiden swarm, as I believe it is called, I put on a good-sized glass super. The bees make no attempt to fill it. I should not have intruded upon you, but I cannot explain the cause of the scattered particles of comb in the front of the hive, and shall feel obliged by a notice of it in your paper.—A BEE-KEEPER.

[The particles of comb arise from the unsealing of the brood, thousands of young bees having quitted their cradles during the past few weeks. Try inserting two or three pieces of guide-comb in the super, and filling the cells with honey or syrup.]

PRESERVING PEAS GREEN FOR WINTER USE.—This desirable result has certainly not yet arrived at the state of perfection we expect of it, and we have heard of many failures; but the following mode has been reported to us by a person well qualified to judge of such matters, as being very successful:—Carefully shell the Peas—then put them in tin canisters, not too large ones; put in a small piece of alum, about the size of a horsebean to a pint of Peas. When the canister is full of Peas, fill up the interstices with water, and solder on the lid perfectly air-tight, and boil the canisters for about twenty minutes; then remove them to a cool place, and they will be found in January but little inferior to fresh, newly-gathered Peas. Bottling is not so good—at least we have not found it so; the air gets in, the liquid turns sour, and the Peas acquire a bad taste.—(*American Gardeners' Monthly*.)

OUR LETTER BOX.

ILL-SUCCESS IN HATCHING (*B. H.*).—Your case is that of many this season, and is in a great measure attributable to the sharp frosts during the spring. The outer eggs get chilled, and then assume the appearance you describe. It is a good plan to put not more than seven or nine eggs under the hens for early hatching.

DORKING COCKERELS (*M. D.*).—If you wish to show Silver-Grey Dorkings, none of those you mention are fit for the purpose. It is imperative that cocks in those classes shall have black breasts and tails. No. 1 has not either. They must also have pale, almost white, hackles and saddle. No. 2 is here at fault; and as in a matter of colour (at least so far as poultry is concerned), comparison is not allowed, the fact of No. 3 being blacker than No. 1, but nevertheless not quite black in breast and tail, will not help you. If you are bent on showing in a Silver-Grey class, if you have hens or pullets of faultless colour, and if No. 2 is perfectly black where required, that is the bird to show. If you are showing for general competition, take No. 1 by all means. It is the height of absurdity to be deterred by a few white feathers on the breast, or a white shade on the tail. You have to look for symmetry and size, and save in a White or Silver-Grey class, colour has nothing to do with decisions.
